Blood count: Reds, 5,050,000; Hb. 79 per cent.; white ells, 4100; differential count normal; eosinophilia on one occasion.

August, 1930, tapped twice weekly, 18, 16, 5, 24 pints on various occasions.

October, 1930, laparotomy; spleen large, exhibiting nfarcts; removed. Liver, marked cirrhosis; no evidence of carcinomatosis.

Death occurred a week later.

Autopsy: Small cirrhotic liver, no evidence of carcinomaosis. Kidneys normal, both macroscopically and microcopically.

Biochemical observations—

Commentary.

The cases referred to above definitely support the theory that depletion of plasma proteins from any cause will lead to the production of œdema. Three of the patients had ascites with high protein content, in the others there was extensive ulceration of the stomach presumably leading to long-continued loss. Loss from the plasma of albumin, rather than of globulin, is known to be characteristic of œdema of the so-called "renal" type, and in this, as in many other respects, the cases described above presented striking similarities to the group often described as "nephrosis." Albuminuria, however, was absent and the blood cholesterol was within normal limits, whereas in nephrosis it is raised.

A recent experimental attempt to imitate the pathological condition occurring in nephrosis has been made by Barker and Kirk. These workers removed successive quantities of blood from dogs, centrifuging the corpuscles down, decanting the specimen, adding an equal quantity of saline, and then reinjecting the corpuscle-saline suspension. In due course the animals developed œdema and hypercholesteræmia, and this "plasmapheresis" was considered by these workers to be comparable to the plasma loss via the kidneys occurring in nephrosis. It is worthy of note that œdema did not appear until the albumin fraction of the plasma had been reduced to below 1 per cent. In the experience of the present authors and others, œdema often appears at a much higher plasma-protein concentration in human beings. Barker and Kirk state that after œdema had developed albumin appeared in the urine, and the kidney when sectioned later showed the characteristic tubal changes of nephrosis. From this they conclude that the kidney was damaged by a lowered plasma-protein content, and accept this as support for the theory that nephrosis is a disease of extrarenal origin.

We feel that the conditions in the cases quoted by us above are closely similar to the plasmaphereses in the dogs of these authors. The depletion of proteins in our cases, sometimes by passage into the peritoneum, sometimes by apparent leakage from ulcerating surfaces, was equal to that occurring in dogs, the duration was in all cases longer, and massive œdema was present in all. It is, therefore, important to note that in not one of these patients was there evidence of renal damage. The urine was free from albumin, casts, red blood-cells, or any abnormal constituent. In three of the cases death occurred, and at the autopsy the kidneys were found to be normal. In the others tests of renal efficiency, such as the urea-concentration and water elimination test, failed to demonstrate any renal lesion. Admitting that such tests are usually negative in early nephrosis, the post-mortem findings in three of the present cases, and the constant absence of proteinuria, may be taken as fairly conclusive evidence that the kidneys were normal in all. We must, therefore, assume that in the human subject the diminution of plasma proteins, even for a considerable time, does not produce changes in the kidney.

The importance of this in relationship to the ætiology of nephrosis is, we feel, very great. The "diabetes albuminuricus" theory ascribes the cause of nephrosis to a modification in the protein molecule rendering it permeable to the kidney, with the result that massive loss occurs in the urine. Œdema then results and the renal changes which occur have been thought to be due to the loss of plasma proteins. Unless it be argued that the mere passage of the abnormal protein through the kidney is capable of

producing renal lesions, it would appear that this argument falls to the ground, since extrarenal plasmapheresis in man does not damage the kidney. This forms a strong argument in favour of the view that the kidney is at least one of the primary seats of damage in nephrosis, and that the renal lesion causes the alteration in the constitution of the plasma proteins, and not vice versa.

SUMMARY.

Massive loss of protein may occur from the blood by routes other than the kidney. Œdema follows this loss, and the mechanism of its production is the same as that operating in nephrosis—i.e., diminution of the plasma proteins. In such cases no pathological changes are produced in the kidneys. This is definitely opposed to the theory that the renal lesions of nephrosis are secondary to plasma-protein depletion, and not vice versa.

We are indebted to Dr. V. Dickinson for permission to publish details of one case.

CANCER OF THE SKIN.

A STATISTICAL NOTE.

By Alex. R. Somerford, M.D. Manch.,

MEDICAL REGISTRAR, MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES; ASSISTANT MEDICAL OFFICER, VENEREAL DISEASE DEPARTMENT, ANCOATS HOSPITAL, MANCHESTER.

THERE is a tendency at the present time for observers to regard cancer, at least in its squamous form, as occupational in origin when it occurs in the skin of a manual worker. There is evidence to demonstrate the occurrence of skin cancer in tar workers and epithelioma of the scrotum in mule-spinners, but few statistics exist on the incidence of skin cancer of other parts of the body in various trades.

The statistics given here are compiled from the patients attending the Manchester and Salford Hospital for Skin Diseases, and to the honorary physicians of the hospital for their kindness in allowing me to publish these figures I tender my sincere gratitude.

Yearly Incidence.—The number of patients attending the skin hospital suffering from cancer of the

TABLE I.

Year.	Patients.	Squamous-celled.	Basal-celled.	Year.	Patients.	Squamous-celled.	Basal-celled.
		%	%			%	%
1919	10,113	22 (0·22)	92 (0·91)	1925	9,489	32 (0·34)	126 (1·32)
1920	10,439	18 (0·17)	93 (0·89)	1926	9,502	47 (0·49)	117 (1·23)
1921	9,644	16 (0·17)	97 (1·00)	1927	9,903	39 (0·39)	115 (1·16)
1922	9,003	26 (0·29)	76 (0·84)	1928	10,267	50 (0·49)	137 (1·33)
1923	9,378	36 (0·38)	106 (1·10)	1929	10,466	67 (0·64)	134 (1·28)
1924	9,418	32 (0·34)	100 (1·06)				

skin increased from 114 in 1919 to 201 in 1929. The increase was most marked in cases of the squamous variety—namely, from 22 in 1919 to 67 in 1929—but a definite increase also occurred in the basal-celled type. The increase was not only in actual numbers but also in the percentage of the total number of patients attending the hospital who suffered from malignant disease.

It is difficult to determine how far these figures can be regarded as a true index of the incidence of the condition and how far the apparent increase is due to better and more careful diagnosis, as the result of which the patients are referred to hospital more frequently. The almost trebled number of patients suffering from the squamous-celled type, however, seems to suggest a true increase in its incidence (Table I.).

Until 1929 the cases were not recorded in detail, but since that date 57 cases of squamous and 175 of the basal type have been noted.

Squamous-celled Carcinoma.

In 14 out of 57 cases the tumour was superimposed on a previously existing lesion; in 11 cases this lesion was lupus vulgaris, while in the remaining 3 it was lupus erythematosus. All these patients had been treated by X ray radiations at some time previously, but in only two cases was there a history of an X ray burn. Our experience did not confirm the common statement that a wart is often present at the site of the tumour; in only one case was there reason to suspect that the injudicious application of caustics to a wart of some years' duration had initiated malignant change in it.

Sex- and Age-incidence.—Males were affected to a greater extent than females in the proportion of 3 to 2. The large number of patients below the age of 40 is accounted for by the number of carcinomata secondary to other lesions which occurred for the most part in early adult life. Apart from these, the largest number of cases in any five-year period occurred between the ages of 65 and 69 (Table II.).

TABLE II.

—	Total.	M.	F.	—	Total.	M.	F.
Below 40..	12	4	8	60–64..	5	5	0

45–49..	6	4	2	70–74..	4	3	1
50–54..	6	2	4	75–79..	2	1	1
55–59..	7	6	1	Over 80..	1	1	0

Occupational Incidence.—In histories of exposure to carcinogenic agents persons performing the same task give different answers. For instance, whereas one stripper and grinder in a mill stated that his clothes and whole body were saturated with oil; another man carrying out the same work said that his skin was never in contact with oil. How far this discrepancy may be due to better conditions obtaining in some mills or to different standards of personal cleanliness in the individual workers it is hard to determine. In examining these figures it must be remembered that they were obtained from hospital practice to the exclusion of the professional and business classes (Table III.).

TABLE III.—*Men.*

Tar workers	5	Railway guards	2	Flyer-maker	1
Carters	2	Mill-hands	6	Paper-maker	1
Labourers	6	Clerks	2	Engineers	3
Colliers	2	Bleacher	1		
Gardeners	3	Window-cleaners	2		

Five of these men had worked in a mill before their present employment, and 13 stated that their previous or present work necessitated the use of mineral oil or tar.

TABLE IIIA.—*Women.*

Housewives	15	Mill-hands	2	Box-maker	1
Hemstitcher	1	Clerk	1	Dyer	1

Six women had worked in a mill before their

marriage, and seven had used oil in the course of their various employments.

Situation of the Lesion.—Forty of the 57 cases had the lesion on the face, while of the four patients who had the tumour on the arm three were tar workers and the other a mule-spinner (Table IV.).

TABLE IV.

Face	40	Limbs	8

Lids	3	Arm	4
Cheek	26	Leg	1
Lips	4	Hand	2
Nose	4	Body	1
Neck	2	Scrotum	6

Basal-celled Carcinoma.

Sex- and Age-incidence.—In this type the women predominated, there being 102 women to 73 men. The greatest number of cases occurred between the ages of 60 and 64, showing a maximum age-incidence in the five-year period preceding the maximum for the squamous type. The incidence for male and female ran approximately parallel (Table V.).

Nose	23	Limbs	2
Lid	3	Elbow	1
Ear	1	Arm	1

From these figures it will be seen that by far the most common situation of both forms of cancer of the skin is the face. This fact, in our opinion, is against an occupational cause, since the face is the part of the body least likely to be brought into contact with irritating substances used in any occupation.

THE DICK TEST IN PREGNANCY AND ITS RELATION TO PUERPERAL SEPSIS.

BY DUGALD BAIRD, M.B., B.SC. GLASG., D.P.H.,
SENIOR ASSISTANT TO THE MUIRHEAD CHAIR OF OBSTETRICS AND GYNÆCOLOGY; ASSISTANT GYNÆCOLOGIST TO THE ROYAL INFIRMARY, GLASGOW;

AND

ROBERT CRUICKSHANK, M.D. ABERD.,
BACTERIOLOGIST TO THE ROYAL INFIRMARY; LECTURER IN BACTERIOLOGY IN THE UNIVERSITY, GLASGOW.

THE Dick test was performed on 600 pregnant women, of whom 22 per cent. reacted positively, the incidence and intensity of positive reactions being greater in primiparæ, irrespective of age, than in multiparæ. Among multiparæ the proportion of strongly positive reactors decreased with increasing age; so also did the incidence of puerperal sepsis, whereas both remained constant for all ages in primiparæ. A correlation between a positive Dick test and susceptibility to puerperal sepsis was thus suggested, but was not supported by further analysis.

Previous streptococcal infection—scarlet fever, tonsillitis, puerperal sepsis—did not appear to influence the reaction to the Dick test. On the other hand, the reaction became negative when Dick-positive patients who had puerperal sepsis, however slight, were retested immediately after the pyrexia subsided.

The puerperia of 500 women in the series were investigated. When all cases of puerperal pyrexia, whether notifiable or not, were divided into puerperal sepsis and pyrexia due to other causes, the analysis showed that women who reacted positively to the Dick test were not more liable to develop puerperal sepsis than were negative reactors. However, infection when it occurred tended to be more severe in the Dick-positive than in the Dick-negative cases. An investigation of the factors predisposing to puerperal sepsis showed that sepsis was much more frequently associated with a difficult or mismanaged labour and/or a poor condition of health than with a positive reaction to the Dick test.

SCOPE OF THE WORK.

During the year 1929 an investigation was conducted at the Royal Maternity and Women's Hospital, Glasgow, into the value of the Dick test—i.e., the cutaneous reaction to the intradermal injection of scarlatinal streptococcus toxin—as an index of susceptibility to puerperal sepsis. Because of the commonly expressed view that the toxins produced by the hæmolytic streptococci causing scarlatina and puerperal fever are identical, it was thought that sensitiveness to the scarlatinal toxin might indicate susceptibility to puerperal sepsis, and, if this were so, that the Dick test might serve as a guide for the prophylactic immunisation of susceptible cases.

The Dick test was performed in a series of 600 pregnant women, either during labour or in the last few weeks of pregnancy. Careful histories were taken on cards specially designed for the investigation, inquiry being made regarding previous streptococcal infection—e.g., scarlet fever, tonsillitis, puerperal sepsis—the obstetric history, and the health during the current pregnancy. Full particulars of the labour and the puerperium were subsequently obtained in 500 cases; a morbid puerperium, even although not notifiable according to the British Medical Association standard, was classed as puerperal sepsis if there was clinical evidence of local

uterine sepsis. Pyrexia due to other causes, such as urinary infection, bronchitis, or operation, was separately classified. A number of Dick-positive reactors who developed pyrexia in the puerperium were retested immediately after the pyrexial period to see if any change in the reaction had occurred. Some of these were again tested six months later.

Method.—The toxin used was the standardised product in use for the Dick test in scarlet fever and was kindly supplied by Dr. R. A. O'Brien, of the Wellcome Physiological Research Laboratories. Initially, two different dilutions of toxin were used, 1/250 and 1/1000, 0·2 c.cm. of each being injected intradermally on the flexor aspect of the left forearm about three inches apart. On the other arm an injection of 0·2 c.cm. of heated toxin served as a control. A positive result was indicated by an area of redness, at least 10 mm. in diameter, appearing within 30 hours, and in the subsequent analysis one plus represents 10–20 mm., two plus 20–30 mm., and so on. In order to determine the optimum dilution of toxin an analysis was made of the first 200 cases in whom the two strengths of toxin, 1/250 and 1/1000, were used. Of these only 16 (8 per cent.) were positive with 1/1000 dilution, whereas 43 (21·5 per cent.) were positive with 1/250 dilution. In all cases where the 1/250 dilution gave a reaction over two plus there was a positive reaction with the 1/1000 dilution, but to a smaller extent. The analyses which follow have, therefore, been based on the results obtained with the stronger dilution of toxin for two reasons: (1) too small a proportion of the women gave a positive reaction with the weaker dilution, and (2) the extent of the reaction with the stronger dilution (1/250) was a measure of the degree of susceptibility to streptococcus toxin.

RELATION OF DICK TEST TO AGE AND PARITY.

Of the 600 cases tested, 135 (22·5 per cent.) gave positive reactions; 44 (25 per cent.) of 179 primiparæ and 91 (21·5 per cent.) of 421 multiparæ. A division of the cases into three age-groups, 15–25, 26–35, and 36–45, showed that the incidence of Dick-positive reactions did not decrease with advancing years either in primiparæ or multiparæ. The impression was formed, while doing the tests, that more marked reactions were obtained in primiparæ than in multiparæ. Consequently the Dick-positive cases were divided into two groups according to the intensity of the reaction: (*a*) those of 1–2 plus and (*b*) those of 3 plus or over. It was found that 39 per cent. of the primiparæ and only 17 per cent. of the multiparæ gave a reaction of 3 plus or over. Primiparæ, however, belong mostly to the youngest age-group, and a more detailed analysis was made to find whether age or parity was the more important factor in determining the intensity of the reaction. In the last column of Table I. it is seen that in multiparæ the percentage of strong reactors diminished steadily from the youngest to the oldest age-group, whereas the primiparæ showed no fall in the percentage of strong reactors in the older age-group. This suggests that the decrease in sensitiveness which occurs with advancing years is due to increased parity rather than to greater age.

If susceptibility to scarlatinal streptococcus toxin is an indication of susceptibility to puerperal sepsis, the preceding analysis would suggest that the incidence of sepsis should be greater in primiparæ than in multiparæ. When 225 patients, in whom the health was good and the delivery normal, were analysed it was found that the sepsis rate in primiparæ was high (26 per cent.),* and was the same for the first two age-groups, whereas in multiparæ it was 11, 7, and 6 per cent. in the first, second, and third age-groups respectively. Of course, in primiparæ spontaneous deliveries which are recorded as being free from lacerations will be accompanied by more unnoticed bruising than spontaneous deliveries in multiparæ, which fact in itself might tend to increase the sepsis rate among primiparæ. However, the correspondence between these figures and those recorded from the previous analysis of the intensity of the reaction to the Dick test (Table I.) might suggest that there exists some relationship between a marked degree of sensitiveness to the streptococcus toxin and a liability to puerperal sepsis. But an analysis of the puerperia of 25 women in whom the Dick reaction was three plus or over showed that there was no sepsis in 17 in whom the health was good and the delivery normal, and no sepsis in seven others where there were predisposing factors, either ill-health or difficult delivery, while one woman who died—probably of sepsis—had both ill-health and a difficult delivery. Thus there was no evidence from this small number of cases that a high degree of sensitivity to the Dick toxin indicates a similar degree of susceptibility to puerperal sepsis.

* This high figure is explained by the fact that even the slightest degrees of sepsis are included.

RELATION OF DICK TEST TO PREVIOUS STREPTOCOCCAL INFECTION.

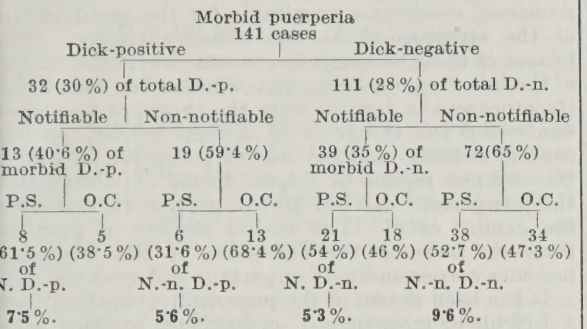
Susceptibility to scarlatinal streptococcus toxin does not appear to be influenced by previous streptococcal infection, if the histories obtainable from this class of patient be accepted. The percentage of positive reactors was the same in patients giving a history of scarlet fever or repeated attacks of tonsillitis as in those who gave no such history: 23 per cent. in the former group and 22 per cent. in the latter. Histories of undoubted puerperal sepsis were obtained in 26 cases, of whom 5 (19 per cent.) were Dick positive. Of course, only the more severe puerperal infections would be recognised as such by the patients. The puerperia of 23 of these cases were observed and only one woman developed puerperal sepsis. These figures are insufficient to decide whether or not a previous puerperal infection protects a woman against subsequent puerperal sepsis.

Dick Test in Relation to Puerperal Sepsis.

Of the 500 cases followed throughout the puerperium the Dick test was positive in 21 per cent.; of these, 12·2 per cent. had puerperal sepsis, according to the British Medical Association standard, compared with 9·4 per cent. of the negative reactors. It was thought advisable to make a further analysis of all cases of sepsis, whether notifiable or not, as puerperal sepsis may occur with very little temperature—e.g., local uterine sepsis, white leg, and low-grade pelvic cellulitis. This analysis (Table II.) showed first that almost as big a proportion of Dick-negative as Dick-positive cases had morbid puerperia. The next subdivision into notifiable and non-notifiable pyrexia showed that the percentage of notifiable cases is slightly higher in the Dick-positive than in the Dick-negative group. Some of the notifiable puerperal pyrexias, however, were due to such causes as urinary infection, bronchitis, and staphylococcal breast abscess, so that a further subdivision

vas made in each group into true puerperal sepsis nd pyrexia due to other causes. The cases of true uerperal sepsis have been expressed as percentages f the total Dick-positive and Dick-negative cases see figures at the foot of Table II.); 8 (7·5 per cent.)

TABLE II.—*Analysis of the Morbid Cases.*



D.-p. = Dick-positive cases; D.-n. = Dick-negative.
N. = Notifiable; N.-n. = Non-notifiable.
P.S. = Puerperal sepsis. O.C. = Other causes.

of the 106 Dick-positive cases developed notifiable puerperal sepsis, and 6 (5·6 per cent.) developed non-notifiable puerperal sepsis—a total of 13·1 per cent.; 21 (5·3 per cent.) of 394 Dick-negative cases developed notifiable puerperal sepsis, and 38 (9·6 per cent.) developed non-notifiable puerperal sepsis—a total of 14·9 per cent. Since statistically there is no significant difference between these figures, it would seem that pregnant women who react positively to the Dick test are no more liable to puerperal sepsis than are negative reactors.

The figures resulting from the division into notifiable and non-notifiable puerperal sepsis suggested that if infection occurs it tends to be more severe in the Dick-positive cases. A more detailed analysis of the cases of notifiable puerperal sepsis in both Dick-positive and Dick-negative groups rather supported that view (Table III.); 3 out of 8 Dick-positive cases died of puerperal sepsis compared with 1 out of 21 Dick-negative cases, one of the latter deaths being due to peritonitis caused by leakage from an infected fibroid. Six cases of puerperal septicæmia recovered; of these 2 were Dick-positive and 4 were Dick negative. Again, 7 out of 8 (or 87 per cent.) of the Dick-positive notifiable cases were suffering from severe sepsis as compared with 10 out of 21 (or 47 per cent.) of the Dick-negative notifiable cases (Table III.). In this small series

TABLE III.—*Details of Patients who Developed Notifiable Puerperal Sepsis.*

Dick-positive cases (8).			Dick-negative cases (*cont.*)

Cellulitis, embolism, death	1				

factors such as poor health of the patient and a difficult delivery, which predispose to sepsis, would affect the figures. On analysis these factors were found to be approximately equal in both Dick-positive and Dick-negative groups, and could therefore be ignored.

REACTION TO DICK TEST AFTER PUERPERAL SEPSIS.

Twenty-one women who had given a positive reaction to the Dick test were retested in the puerperium; 13 of them remained positive, and of these two had puerperal pyrexia due to a coliform pyuria. In the remaining eight cases there was sepsis, slight in six and severe in two, and in all of them the reaction to the Dick test became negative. An attempt was made to retest all these patients six months later, but unfortunately only three of those who had become Dick negative in the puerperium could be traced. One was again Dick positive; the other two remained Dick negative. All the women who had been Dick positive before and after delivery still reacted positively.

PUERPERAL MORBIDITY IN RELATION TO ILL-HEALTH AND DIFFICULT LABOUR.

The relative importance as factors in the production of puerperal sepsis of the reaction to the Dick test, the general health of the patient, and the type of delivery is indicated in Table IV. The figures

TABLE IV.—*Relative Importance of Reaction to Dick Test, Bad General Health, and Difficult Delivery in Puerperal Sepsis.*

Factors present.	Dick positive.	Dick negative.
Good health and normal delivery.	Afebrile .. 47 Febrile .. 6 (11·3%)	Afebrile .. 237 Febrile .. 22 (8·5%)
Bad health only.	Afebrile .. 11 Febrile .. 2 (15·4%)	Afebrile .. 24 Febrile .. 9 (27·5%)
Difficult delivery only.	Afebrile .. 23 Febrile .. 8 (34·7%)	Afebrile .. 37 Febrile .. 43 (54%)
Bad health and difficult delivery.	Afebrile .. 2 Febrile .. 7 (77%)	Afebrile .. 7 Febrile .. 17 (70%)

emphasise the fact that a difficult delivery was the most important single factor and bad general health the next; when both these factors were present 70 per cent. of the women had morbid puerperia. A positive reaction to the Dick test was the least important factor predisposing to sepsis. This was emphasised by the finding that if, from the 500 cases with a notifiable sepsis rate of 12·8 per cent., those women with good health and normal delivery (225 cases) were abstracted, only 4 (1·7 per cent.) of the latter had notifiable sepsis and all four had perineal tears requiring several silkworm sutures; two of them were Dick positive and two Dick negative. The rate of notifiable sepsis for the remainder of the 500 cases was 22 per cent.

Discussion.

Since this investigation was commenced several papers have appeared on the subject. Burt-White, Colebrook, and others (1930) gave the results of 1000 cases investigated at the London Maternity and Queen Charlotte's Hospitals. They suggested that women with a Dick-positive reaction have an increased susceptibility to puerperal sepsis, since the morbidity among Dick-positive cases was 41 per cent. greater than in the Dick-negative group. In our investigation there was very little difference between the respective morbidity-rates of the Dick-positive and Dick-negative groups. In their series cervical swabs were taken in morbid cases but in

only 8 was the *S. pyogenes* isolated: in 2 out of 770 Dick-negative cases (0·26 per cent.) and in 6 out of 230 Dick-positive cases (2·6 per cent.). The authors therefore state that the incidence of *S. pyogenes* infection in the puerperium is ten times greater in Dick-positive than in Dick-negative cases. However, the fact that hæmolytic streptococci were not isolated from cervical swabs does not prove conclusively that the streptococcus was not the infecting organism. For example, in our series the Dick reaction became negative when Dick-positive patients who had sepsis, however slight, were retested after the pyrexia subsided, but it remained positive in those who had a coliform urinary infection. The incidence, in Burt-White and Colebrook's series, of only one case in which a few colonies of *S. pyogenes* were isolated out of 38 Dick-negative cases with morbid puerperia is at variance with our findings, where 10 out of 21 Dick-negative cases (47 per cent.) with notifiable puerperal sepsis had a type of infection so severe as almost certainly to be due to the hæmolytic streptococcus.

Salmond and Turner (Royal Free Hospital) and Stent (St. Mary's Hospital, Manchester) have also recorded their results obtained in two series of 533 and 500 pregnant women respectively. In neither investigation was there significant evidence to support the view that a positive reaction to scarlatinal toxin is an index of susceptibility to puerperal sepsis. Stent, who divided her morbid cases into three grades of severity, found a higher incidence of severe sepsis in the Dick-positive than in the Dick-negative group: 4 out of 14 as compared with 5 out of 46. Although these figures were not emphasised by the author on account of the small numbers, they correspond with our results, which show that, out of eight Dick-positive cases with notifiable puerperal sepsis, seven (87 per cent.) had severe infections, whereas only 10 out of 21 (47 per cent.) of the similar Dick-negative group had severe sepsis. Theoretical considerations would suggest that these findings may have some significance. Streptococcal antitoxic immunity does not prevent the invasive action of the *S. pyogenes*, as is shown by the occurrence of streptococcal tonsillitis in individuals artificially immunised to streptococcal toxin, but the immunity might be expected to modify the severity of the infection—as in fact it does, for these immunised individuals do not develop scarlet fever. We therefore suggest that, although a negative reaction to the Dick test in a parturient woman does not indicate an insusceptibility to streptococcal infection in the puerperium, it reveals an antitoxic immunity of a degree which may modify the severity of infection and help to localise it should it occur.

PROPHYLAXIS.

It follows that puerperal sepsis may be wholly prevented only if women are protected against the hæmolytic streptococcus itself. Unfortunately the tissues seem to be unable to establish an efficient or permanent barrier against the invasive action of the streptococcus—witness, for example, the recurrences of erysipelas and streptococcal tonsillitis. Thus, a system of immunisation with streptococcal vaccines would probably afford inadequate protection, although Lash (1929) claimed to have reduced the incidence of puerperal sepsis in a series of women who were given a vaccine containing streptococcal toxin plus the killed organism. In our series multiparæ tended to give less intense reactions to the Dick toxin and appeared also to be less susceptible than primiparæ to puerperal infection, facts which might possibly be attributed to a combination of antitoxic immunity plus antibacterial immunity conferred by infection in previous confinements, but was probably due to other causes.

If antistreptococcal immunity cannot be obtained the prophylaxis of puerperal sepsis may be attempted either by preventing access of the hæmolytic streptococcus to the parturient woman or, if that fail, by rendering conditions unsuitable for the proliferation of the streptococci in the woman's tissues. The former of these measures is concerned with the source of the infecting organism, and, whether the hæmolytic streptococcus is derived from the throat of an attendant—and the throat is its natural habitat—or by contagion from another case of puerperal infection, the strictest régime of asepsis during childbirth and the puerperium will not always prevent its access to the genital canal. The second method of prophylaxis—to increase the resistance of the woman—becomes correspondingly important and essential.

It has been shown in the present investigation that a difficult or mismanaged confinement, together with a poor condition of health, greatly increases the woman's susceptibility to puerperal infection. We are entirely in agreement with Young's dictum: "To trauma from interference must be credited the chief agent in the maintenance of sepsis." The obvious remedies are more thorough antenatal care and a better obstetric service. Until this ideal is attained some means of protecting "suspect" cases is desirable. Of course, sepsis may occasionally occur in the absence of predisposing factors. Scarlatinal streptococcus antitoxin has been used successfully in the prophylaxis of scarlet fever; we would accordingly suggest its use in doses of 5–10 c.cm. at the confinement of women who for various reasons are to be regarded as "suspect" cases. In a series of women thus treated (Thomson, Bellshill Hospital—personal communication) the incidence of puerperal infection has been reduced by half. It is to be hoped, however, that if there is an antigenic identity among the strains of puerperal streptococci an antibacterial serum may be produced for prophylactic use against the invasive action of the hæmolytic streptococcus.

DERBYSHIRE HOSPITALS: INCREASED ACCOMMODATION.—The Derbyshire County Mental Hospital at Mickleover has been enlarged by the addition of 12 houses for medical attendants, a nurses' home, and an admission hospital. The work has cost over £92,000. The nurses' home provides 71 bedrooms and other accommodation. The admission hospital will contain 50 patients on each side, in dormitories and single rooms, and there is a very complete bathing installation.—The employees of Rolls-Royce, Ltd., at a cost of £1000, have endowed a bed in Derby Infirmary. They have in contemplation the provision of a second bed as well as one in the children's hospital. Since 1914 the employees have subscribed £8000 to the infirmary, which during the past year has treated 223 in-patients and 1087 out-patients from the Rolls-Royce Co. at a cost of £1834.—Reviewing the hospital accommodation of Derbyshire, Dr. W. M. Ash, the county medical officer, states that there is much overlapping, and that there are too many instances of a small centre of population possessing two and three, and sometimes more, institutions for the sick, each confining its activities to one type of case or one class of person. "As a general policy," he adds, "there should be one hospital for any area, and the work of that hospital should be as comprehensive as medical and other circumstances permit," and he suggests that the county council should not support small institutions which fall behind in the march of medical progress.

CLINICAL AND LABORATORY NOTES

A CASE OF MEGACOLON

OF MANY YEARS' DURATION WITH UNUSUAL ATTACKS OF PAROXYSMAL TACHYCARDIA.

BY H. J. STARLING, M.D. LOND.,

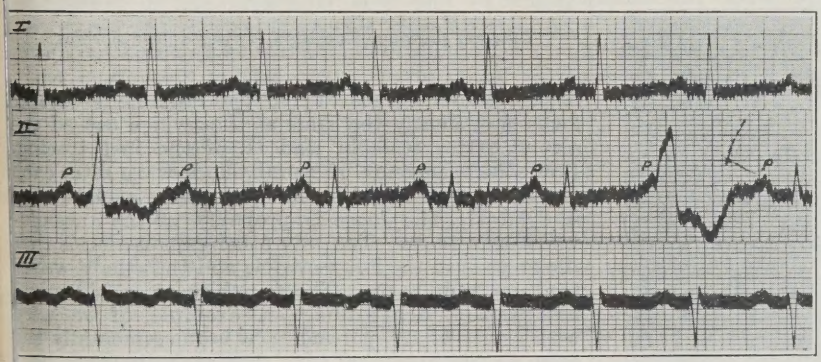
HON. PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL.

THE essential lesion of the colon described in his case was a volvulus of the sigmoid flexure which had never become so complete as actually to occlude the lumen of the bowel. Gould's "Medical Dictionary" defines volvulus (volvere, to roll) as 'a twisting of the bowel upon itself so as to occlude the lumen. . . .'

The patient was first seen by me in April, 1925; she was then 48 years old. She had been delicate all her life and had suffered from constipation and sickness, especially in childhood. Her present trouble began at 24 years when she saw a consultant for constipation and "nerves"; no cardiac abnormality was noted then. A few years later she had severe gastritis and the heart was said to be irregular and intermittent; she rested for five years, with some improvement. At 31 she had a curious heart attack, said by one doctor to be functional but by another to be serious, and she was continually in bed after this. In 1914 she saw a London consultant who diagnosed a congenital heart lesion.

When I saw her first she had been confined either to her room or to her bed for ten years. She was lying on a couch but, even so, showed slight dyspnœa. There was some pallor of the face, the general nutrition was good, and the teeth were sound, but there was marked pyorrhœa of the gums. The heart was slightly enlarged, there were no bruits, the sounds were tic-tac, the pulse-rate was 150 to 160, and the blood pressure 150/110. On standing up for some minutes the toes, then the feet, and then the legs became at first congested, then a deep red, then definitely cyanosed. This congestion gradually increased until at the end of ten minutes the upper part of the thighs was a deep red, and the colour increased downwards to a deep purple. The patient informed me that if she stood for much longer the congestion extended up as high as the upper part of the chest, when she would also have marked œdema of the left leg and slight œdema of the left hand and right leg. The abdomen was not distended but the percussion note all over was hyper-resonant.

Electrocardiogram 1.

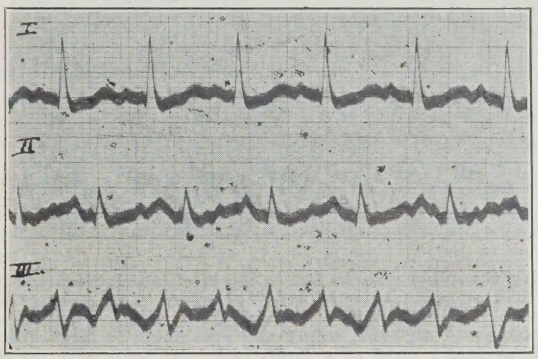


He was only having two motions a week and these only with the aid of suppositories.

In July, 1925, she was brought to a nursing-home and the first electrocardiogram was taken. This shows a left ventricular preponderance, T 3 inverted, and two extrasystoles in lead II. Whilst in the nursing home it became evident that there was something seriously wrong with the intestinal tract; very large enemata failed to secure any result, and the motions suggested that the intestinal contents were being held up in some part of the tract. X-ray examinations were then made by Dr. J. S. Levack of Norwich.

The stomach appeared as an elongated organ extending from the left side to the extreme right of the abdomen; it was situated high up, under the costal margin, and curved over a huge distended coil of intestine. The passage of the barium meal was not unduly delayed and in five hours it had reached the cæcum. In 24 hours the barium was seen passing up the ascending colon into the transverse and descending parts, which also were situated above and around the aforementioned distended coils, but it did not reach the rectum until the end of 48 hours. A barium enema was then given, but the ordinary quantities failed to reach the ascending colon, and not until ten pints had been administered was this part of the colon filled. These distended coils were seen in all the films, but the barium was not observed to pass in or out of them at any time.

Electrocardiogram 2.



On these findings a diagnosis was made of incomplete volvulus of the sigmoid flexure. The patient was seen by Sir Hamilton Ballance, who advised an exploratory laparotomy with a view to resection of the volvulus if this was found to be feasible, but the patient refused to undergo any operative procedure.

As the result of treatment by colonic lavage, massage, liquid paraffin preparations, and dental extractions, the condition of the patient was greatly improved; she was able to be up and about to a limited extent, there was only slight œdema of the legs after being up for some hours, and only slight discoloration of the legs after standing still for ten minutes; there was a loose action of the bowels either daily or every other day.

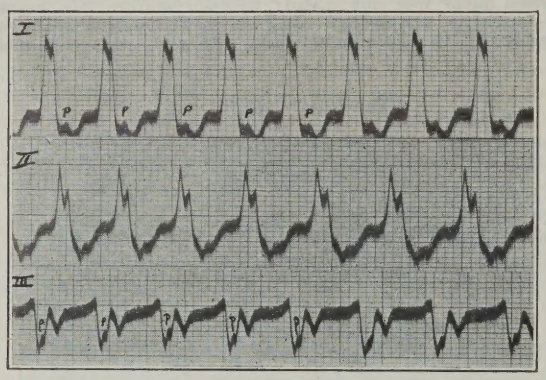
It was remarkable that at no time did the contour of the abdomen suggest any undue distension. Palpation sometimes revealed a certain degree of tension, and the percussion note was always tympanitic, especially in the upper part of the abdomen and the lower half of the chest. This suggested that the pressure of the distended guts was exerted in a vertical rather than in an anteroposterior plane.

The patient returned home in October and led a comparatively active life until March, 1926, when she began to have curious fainting attacks and periods of irregular tachycardia. She came into the nursing-home again in May, 1927. She described very vividly three different types of heart attacks. The first type she called "barge-poling"; during this phase the pulse was extremely irregular, the whole chest heaving with the violence of the heart's action, and the rate varying between 140 and 170. The next type was described as "quick-beating," at a rate of 195. The third type was known as "hitching," and very aptly so. The first type was the most uncomfortable, but was brief and transitory, leading to type 2, during which she was able to be up and about, write letters, and do other work at a slow pace, or to type 3, during which she had to rest. The second type was the most prolonged and sometimes lasted

as long as 24 hours. The three types are represented in electrocardiograms 2, 3, and 4.

During the next three years these attacks of tachycardia slowly but surely increased in frequency, duration, and severity. In spite of them the patient kept up and about

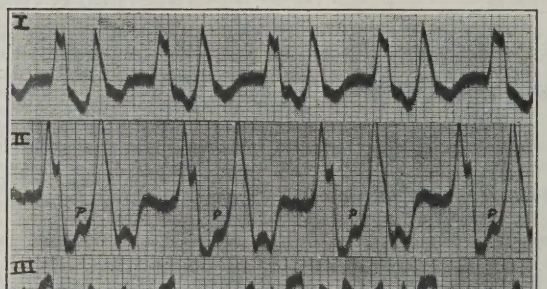
Electrocardiogram 3.



during the minor attacks and in the brief interludes between the bad ones, and even during the severe attacks she was able to do much writing, resting on a couch. Quinidine sulphate and digitalis, singly and combined, in large doses and for many days at a time, failed to bring any relief, but the French tinct. iodi, taken in milk in ten-minim doses thrice daily for a month at a time, proved to be of great value. The bowels were relieved by enemata, but as time went on the amount of fluid had to be increased to 5 pints or more before they were effectual. During her last stay in the nursing-home in November, 1929, during the course of her daily massage, she had a severe fainting attack followed by general convulsions and loss of consciousness for some hours, due probably to a cerebral embolus. In the early part of 1930 the attacks of tachycardia were almost continuous, and early one morning in April she was found to have died quietly about one hour after she had been seen to be sleeping peacefully. A partial post-mortem was allowed.

On opening the abdomen and thorax the following disposition of the viscera was observed (see Diagram). A double loop or volvulus occupied the greater part of the abdomen, the distal part arising from the sigmoid flexure and the proximal part ending close to the distal end, in the lower part of the ascending colon. The descending and transverse parts of the colon were twice

Electrocardiogram 4.



(and in parts three times) the normal size and the latter was lying high up under the costal margin. Above this again was seen the stomach, the major portion of which was on the left side at the level of the fifth to the seventh ribs, but the duodenal portion was enormously elongated, stretching across to the right seventh rib in the mid-clavicular line. The upper limit of the diaphragm on the right side was at the third rib, the liver occupying the space below this, and on the left side was at the fifth rib. The heart was slightly larger than normal, the muscle appeared to have a good colour and consistency, and the valves were normal.

From the close conjunction of the distal and proximal ends of the volvulus it would appear that the operation for its removal, as suggested in 1925, would have been comparatively safe and probably effectual, especially since the volvulus was remarkably free from adhesions to surrounding structures.

The electrocardiograms are of unusual types. The first, taken in 1925, shows a normal sinus rhythm and left ventricular preponderance. In lead II. are two extrasystoles, each of a different type and both occurring after a normal P-wave, thus replacing the usual ventricular sequence. In the second, leads I. and II. show a normal sinus rhythm of 135–140 per min., but lead III. shows an anomalous paroxysmal tachycardia of a rate of 217 per min. The third, taken in 1927 during an attack of paroxysmal tachy-

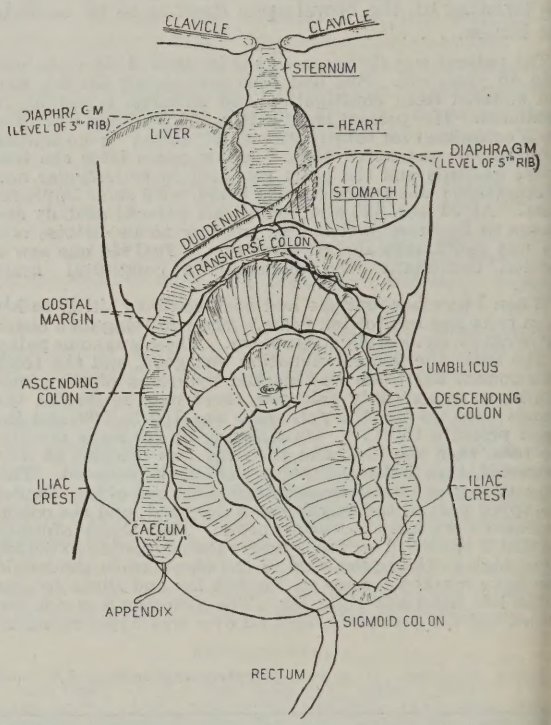


Diagram showing disposition of viscera post mortem.

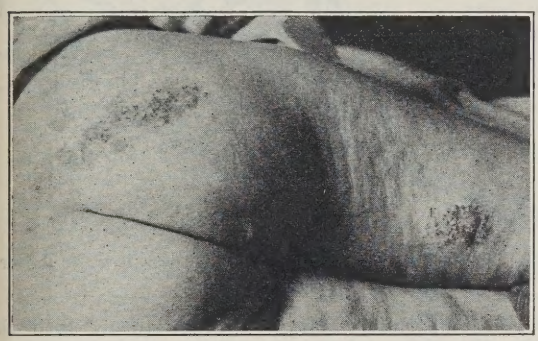
cardia, shows a rate of 195 per min. The ectopic focus is evidently the same as that which caused the second extrasystole in lead II. of the first tracing. From the occurrence of a probable P-wave after each R-wave in lead I. and in the up-stroke of each S-wave in lead III. the focus is probably in the auriculo-ventricular node. The only other explanation is that the focus is in the left ventricle and that the P-waves are retrograde beats. The fourth shows a bigeminal paroxysmal tachycardia, an example of re-entry with a rate of 195 per min.; it is fundamentally the same as the preceding type, but each alternate beat is replaced by an extrasystole arising from a different focus, probably the same as that which caused the first extrasystole in lead II. of the first electrocardiogram.

These types persisted until the last records taken in 1929. The only type not recorded was one described as a "slow hitch," during which the pulse-rate was 60 to 80; the patient was completely incapacitated, and the venous polygraphic record suggested a flutter at a very high rate.

HERPES ZOSTER OF THE FIFTH LUMBAR NERVE.

By Rupert Waterhouse, M.D., F.R.C.P. Lond.,
PHYSICIAN TO THE ROYAL UNITED AND ROYAL MINERAL WATER HOSPITALS, BATH.

The following case, seen in consultation with Mr. A. de V. Blathwayt on August 14th, seems worthy of record. It was that of a lady, aged 74, suffering from typical herpes zoster, evidently resulting from inflammation of the fifth lumbar nerve root ganglion on the right side. The distribution of vesicles was as follows. They covered the dorsum of the foot and of the first three toes, and the inner half of the fourth toe; vesicles were also present on the ventral aspect of the first three toes. In addition, they occupied the whole of the outer surface of the leg below the knee, two particularly prominent collections



Photograph of buttock and thigh, showing lesions.

being present in the neighbourhood of the head of the fibula. But what is of peculiar interest is the fact that in the very centre of the posterior aspect of the thigh, midway between the fold of the buttock and that of the knee, was situated an oval patch of vesicles measuring 2½ in. from above downwards, and about 1¼ in. from side to side: higher up again was another similar but larger patch commencing 1 in. above the termination of the internatal cleft and extending downwards and outwards, across the buttock, for some 6 in. and being about 2¼ in. in breadth.

The importance of this case consists in the light it throws on the sensory distribution of the fifth lumbar nerve, since it is extremely improbable that more than one nerve root was involved.

Most authorities deny any sensory distribution to the fifth lumbar nerve root above the knee, and this has been a great obstacle to complete acceptance of Prof. J. A. Sicard's view that one of the chief causes of sciatica is irritation of the fifth lumbar nerve during its passage through the intervertebral canal (funiculitis), or of Prof. V. Putti's that sciatica is symptomatic of inflammation of the joints between the articular processes of the lumbar vertebræ and between the fifth lumbar vertebra and sacrum. Neither of these theories satisfactorily accounts for the pain in the back of the thigh, usually the most prominent symptom in sciatica, if innervation of this part is from the second sacral nerve only, as the text-books would have us believe. But if (as this case suggests) the fifth lumbar nerve in some persons, and perhaps in many, reaches the surface in this region, to however small an extent, one great difficulty in accepting the explanations of these distinguished observers is removed. Probably herpes zoster is a more trustworthy guide to sensory distribution than information gleaned from sensory loss. Especially would this be so in the case of a small area such as that found on the back of this patient's thigh, since there might be considerable overlapping by other sensory roots.

It is of interest that this patient had had an attack of sciatica in the opposite (left) limb 12 years ago, which lasted three months.

SPIROCHÆTES IN THE FÆCES OF PATIENTS WITH BLACKWATER FEVER.

By L. Soromenho, M.D. Lisbon, L.M.S.S.A. Lond.,
DISTRICT HEALTH OFFICER IN PORTUGUESE EAST AFRICA.

The most striking feature in the symptomatology of blackwater fever is the predominance of the biliary symptoms—namely, bilious vomiting, icteric colouring of the skin, and bilious fæces. This fact led me when trying to find clues to the ætiology of this fever to examine the bile.

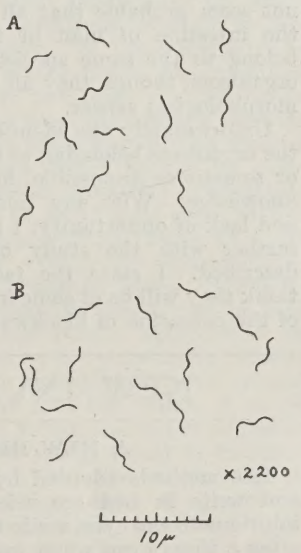
In December, 1928, in Tete, Portuguese East Africa, I made an examination on a patient who had died six hours previously with a severe attack of this disease; the gall-bladder was punctured aseptically, and I aspirated some bile with a syringe. Films were made from this bile, dried, fixed by heat and stained with carbol-fuchsin. They showed innumerable spirochætes. In all patients suffering from this disease whom I had the opportunity of seeing during the next three months, I looked for the parasites in the blood, urine, and fæces with the following results:—

(*a*) In all the cases of blackwater fever submitted to investigation (four in Tete and three in Lourenço Marques) I found spirochætes in the fæces. The parasites were abundant during the feverish stage of the disease but began to diminish as soon as the patients improved, and disappeared altogether in every case when the patients entered on convalescence.

(*b*) I could not demonstrate any spirochætes in either the blood or urine of the patients.

(*c*) In the fæces of a few cases (four) of quinine hæmoglobinuria (at the beginning indistinguishable, by its symptoms, from true blackwater fever), I was unable to find any spirochætes.

I examined at the same time the fæces of patients suffering from other diseases, and found that: (*a*) in 14 white patients (with intestinal complaints) I could not demonstrate the presence of spirochætes in the fæces; (*b*) in 23 natives (all suffering from intestinal troubles) I found spirochætes in the fæces of six.



Spirochætes seen in stained preparations. A = Patient with blackwater fever, Tete's Hospital. B = Patient with blackwater fever, Lourenço Marques Hospital.

The spirochætes found in the fæces (and bile) of the patients with blackwater fever are small filaments measuring from 3 to 7 μ in length, very thin and with one to four spirals. The stain that gave the best results was diluted Ziehl's carbol-fuchsin, allowed to

act for ten minutes. The figure shows some of the forms found in the stained preparations.[1]

The morphological characters of this spirochæte allows us to classify it in the genus *Treponema eugyrata* Werner, 1909. The spirochætes found in the fæces of the sick natives were in two cases indistinguishable morphologically from the parasites seen in the fæces of the white men suffering from blackwater fever.

CONCLUSIONS.

Has this spirochæte any connexion with the ætiology of blackwater fever or is it only one form of the *T. eugyrata*, a normal saprophyte of the human stools? The idea of considering blackwater fever as a spirochætal disease fits in well with its symptomatology, which is similar to that of other pathological conditions with a proved spirochætal causation—namely, spirochætosis icterohæmorrhagica,—due to the *Leptospira icterohæmorrhagiæ*. Schüffner (1918) was the first investigator to associate the origin of blackwater fever with the symptomatology of a case of spirochætosis in a native in Java. Blanchard and Lefrou (1922) have described the appearance of a specific spirochæte in the blood (deposit of the third centrifugation) of white patients suffering from blackwater fever in the French Congo. These results have not, however, been confirmed by J. G. Thomson (1924) in Rhodesia.

The morphology of the parasite described here cannot furnish any definite conclusions on its pathogenic or saprophytic nature. It is a fact that in the fæces of normal men and animals there have been described spirochætes belonging chiefly to the species *T. eugyrata* and *T. stenogyrata* Werner, but it is true also that various investigators (Dantec, Fantham, Thomson) have described parasites of a similar morphology (the same species?) associated with different pathological conditions occurring in man (dysentery, anæmia, rheumatoid arthritis). It does not seem probable that all the spirochætes found in the intestine of man in these different conditions belong to the same species of innocent saprophytic organisms, though they all seem to have an identical morphological aspect.

Unfortunately the identification and separation of the organisms belonging to this group is very difficult, or sometimes impossible, in the present state of our knowledge. With my limited laboratory resources and lack of opportunity, I have not been able to go further with the study of the spirochætes above described. I state the facts I have found, as I think they will be of some interest in the investigation of the causation of blackwater fever.

[1] I owe the drawing of these pictures to the kindness of Dr. J. G. Thomson, School of Tropical Medicine, London, to whom I am much indebted.

NEW INVENTIONS

A NEW BED DESK.

THE methods adopted by those who wish to read and write in bed are scientifically bad and often injurious to the eyes, while the discomfort engendered after a time, even when well propped up by pillows, makes both reading and writing, and especially the latter, only possible for limited periods. In both reading and writing the chief difficulty lies in securing a steady support for the book or writing pad at a convenient angle, which must be varied according to the position of the head and shoulders when propped upon pillows. In addition, so far as writing is concerned, a support is required for the right arm and hand, for writing without such support is difficult and soon becomes fatiguing. With the help of Messrs. Hamblin I have designed a bed reading and writing desk, which does away with faulty and uncomfortable attitudes, and makes reading and writing in bed as easy as when sitting in an armchair or at a table. I hope that the apparatus will prove to be a great comfort to invalids and the bedridden, and also to that large section of the community which habitually reads itself to sleep.

The main feature of the design is a stout light board of suitable height and breadth, which is

The bed desk in use; the angle of the desk is made flatter for writing.

shaped elliptically below in order to fit into the body, the right side of the ellipse being lengthened to form a slightly curved tail which runs away behind the body and rests with its lower edge on the bed. The board thus fits the body as the patient reclines propped up by pillows, the tail of the board forming a support for the right arm of the patient when writing. This is shown quite clearly in the drawing of the desk in actual use (see Figure). The support for the board is furnished in a simple fashion in two ways. On the right side there is a double sliding arrangement which is clamped by a screw, easy to reach and to manipulate. This slide regulates the angle at which the board is supported, and at the same time affords a horizontal bearing along the bed, no matter at what angle the board may be clamped, keeping the board absolutely secure and fixed. On the opposite side of the board there is a non-sliding support also clamped by a screw. This support projects from the board at an angle easily regulated by the patient, so that its lower end rests comfortable on the left side of the bed. The object of this second support is to counteract the tendency of the board to be pushed over to the left by the pressure of the right arm when writing, and to give extra stability to the board when it is supporting a book. The apparatus can be folded up flat when not in use, and erected and folded up again by the patient with little effort.

The bed desk has been very well made by Messrs. Hamblin, Ltd., of 15, Wigmore-street, W., who have patented it and have registered for it the name of the "Kangaroo" bed desk, because it "supports itself by its tail." The desk can be supplied with the tail on the left side and the supports reversed for a person who can use only the left hand for writing or turning the leaves of a book.

Harley-street, W. ARNOLD LAWSON, F.R.C.S. Eng.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN WINNIPEG.

(*Continued from p. 802.*)

SECTION OF DISEASES OF CHILDREN.

The President, Dr. ROBERT HUTCHISON (London), being in the chair, Dr. K. D. WILKINSON (Birmingham) opened a discussion on

Colon Bacillus Infections.

As a clinician, he said, he was familiar with a *B. coli* infection of the urinary tract, frequently seen in children in an acute, chronic, or recurrent form, commoner in girls than in boys, and not often fatal. The name pyelitis had been given to this condition, and although he was unable to prove that it was always a pyelitis, he felt justified in holding the opinion that it was not always part of a septicæmia or evidence of a nephritis—as some pathologists maintained. Many cases, especially the milder ones, might easily be overlooked if the urine of patients were not systematically examined, with a microscopic investigation of the sediment and culture of a fresh specimen, and the difficulty of obtaining specimens from infants and young children in general practice, with the consequent neglect to examine the urine, doubtless resulted in the omission to diagnose many of the less severe cases. The typical urine is pale and opalescent, contains a varying amount of protein, and microscopically shows pus and *B. coli*. Clinically the disease may start as early as the first week of life (some say it may even be present at birth), gradually becomes more frequent, and tends to diminish in frequency after about the eighth year. At first boys and girls are about equally affected, but after the age of one year the preponderance of girl patients gradually increases, though recent authors have found that the preponderance of girls over boys is not so great as was formerly thought to be the case. Of 117 cases—probably severe cases as they all needed hospital treatment—seen at the Birmingham Children's Hospital only nine (or 7·7 per cent.) died, which he held was weighty evidence against the recent pathological view that these cases were all due to a severe septicæmic condition with renal infection and possibly abscess formation.

Cases might be acute, subacute, or chronic, the acute often starting with a rigor or convulsions, high fever, and severe general disturbance, so that pneumonia, meningitis, or a typhoid infection may be suspected. If the possibility of pyelitis is borne in mind, and the urine examined, the diagnosis is usually readily made in these cases. In older children the symptoms and signs are less puzzling, as localising symptoms, such as tenderness in the loin, frequency of micturition, or dysuria, are found present in the majority of cases. When, however, unusual symptoms, such as vomiting, increased respiration-rate, vague aches and pains, or abdominal discomfort or tenderness are present an erroneous diagnosis of acidosis, pneumonia, rheumatism, appendicitis, or abdominal tuberculosis may be made. Subacute or recurrent cases, with fever and attacks of vomiting, simulating cyclical vomiting, may remain undiagnosed until pus and *B. coli* are found in the urine. Chronic cases may show slight signs of a general upset, with perhaps slight fever, general lassitude, anorexia, or nervousness—symptoms apparently quite unconnected with the urinary tract.

As a general rule, acute cases of all ages did well under strict treatment, though some failed to respond at all, and others did only moderately well, and became subacute or chronic. In cases which were subacute when first seen treatment had to be more prolonged to effect a cure, and in some cases what ever line of treatment was adopted proved valueless—the bacilluria persisted, and often such cases showed evidence of damage to the kidneys—the presence of casts in the urine, a high blood-urea or poor urea concentration. The prognosis in such cases was bad. In his experience there were four important requisites in the successful treatment of these cases: (1) As early diagnosis as possible, with institution of the correct treatment, (2) Rest in bed, until the bacilli have disappeared from the urine. (3) The administration of alkalis, such as plentiful doses of sodium bicarbonate or potassium citrate, given with syrup and some flavouring agent. For some years he had been in the habit of treating these cases by alternate alkaline and acid medication whereby the pH of the urine was being constantly varied; first alkalis are given till the urine is definitely alkaline, then a mixture of hexamine with acid sodium phosphate until the urine becomes acid, when the sequence is repeated. This line of treatment is inimical to the *B. coli* as well as to other urinary micro-organisms, but he did not think that the hexamine itself did much good; neither did the other antiseptics, salol or hexyl resorcinol, taken by mouth or those usually recommended to be tried locally. (4) The fourth point in the treatment is the flushing of the kidneys by a large fluid intake—as much as 50 or 60 or more ounces of fluid a day. In his experience vaccines occasionally seemed to be useful, but far more often proved disappointing.

According to McKhann 20 per cent. of children with chronic pyuria showed some abnormality of the urinary tract, which either predisposed the tract to infection or enabled a fortuitous infection to persist owing to the abnormality. In 153 consecutive post-mortems on children Bigler found abnormalities of the urinary tract in 13 per cent. In this series of 20 cases, only four died from the urinary tract infection, and as the eldest of these was only six weeks old, congenital abnormalities could hardly be said to have played a large part in this series in predisposing to urinary infection. In all chronic cases of pyuria Dr. Wilkinson recommended the taking of a cystogram and a further cystoscopic examination in doubtful or definitely abnormal cases. Bowel infections and chronic appendicitis which may be accompanied by pyuria should receive appropriate treatment. He then referred to the pathological studies of Chown and of Wilson and Schloss, who concluded from their observations that the pyuria of so-called pyelitis was really due to an interstitial suppurative nephritis, and that there was generally no evidence of pyelitis. In his opinion the cases studied by those authors were not ordinary cases of pyelitis, but instances of severe septicæmic conditions due to other micro-organisms, and that the *B. coli* was probably a secondary invader. He referred also to Helmholz's experimental work on rabbits, which showed that spontaneous *B. coli* infections occur in these animals, and that intravenous injections of *B. coli* may give rise to kidney abscesses, though these do not occur in the spontaneous infection.

In adults, said Dr. Wilkinson, *B. coli* infections were much commoner in women than in men, and furthermore, they generally produced little upset and were probably often missed. He believed that the facts pointed definitely to an ascending

rather than to a blood infection, and that they supported the clinical findings of pædiatricians that pyelitis is generally an ascending infection, with a correspondingly greater incidence in girls.

SEVERAL PROBLEMS TO SOLVE.

Dr. DAVID NABARRO (London) said it would be interesting to compare current views with those prevalent in 1910, when the same subject was discussed at the seventy-eighth annual meeting of the Association. There were, he said, several interesting problems to solve. (1) *B. coli* was normally a harmless intestinal saprophyte; what was it that made it pathogenic in the bowel or enabled it to leave the bowel for foreign parts? It might be that there were different strains—e.g., hæmolytic and non-hæmolytic (Dudgeon, Wordley, and Bawtree), others with variations in sugar fermentative power, in agglutinability and so forth, which might perhaps be associated with variations in pathogenicity. (2) By what route did the *B. coli* travel from its normal situation to the urinary passages? There were three possibilities, each of which had its supporters: (*a*) directly, via the urethra, the so-called ascending mode of infection, favoured by Dr. Wilkinson among others; (*b*) via the blood stream; and (*c*) via the lymphatics.

Blood culture experiments he had made some years ago on cases of pyuria and bacilluria with negative results had convinced him that the infection was probably not, as a rule, blood borne. He also cited Helmholz's recent paper, with the conclusions that author drew from his experiments—the most important of which was that in the rabbit the infection was of the ascending type, and that in children infections with the *B. coli* took place in the same way. Bugbee, Wilson and Schloss, Chown, and others, on the other hand, think that the infection is blood borne in those cases in which no congenital abnormality interferes with the urinary flow. In Dr. Nabarro's view a blood-borne infection was possible in a small proportion of the cases, but in the majority of the cases the infection of the bladder was probably direct (ascending) and the infection reached the kidneys via the peri-ureteral lymphatics.

Turning to the pathological anatomy of the condition, Dr. Nabarro said there was little or no direct evidence that the condition was really one of pyelitis, and already in 1910 Jeffreys, Thiemich, and Forbes had described suppurative lesions in the kidneys with, in some cases, a normal pelvic mucosa. More recently Chown, Wilson and Schloss, Bugbee, Helmholz, and others had emphasised the fact that the commonest lesion in the type of case under consideration has a diffuse interstitial nephritis, giving rise to suppurative foci of varying size, so that it was more correct to call the condition pyelonephritis than a simple pyelitis.

Discussing the bacteriology, Dr. Nabarro stated that *B. coli* was undoubtedly the commonest organism present in these cases, but that it might be associated with *B. proteus*, streptococcus, *B. lactis aërogenes*, and several other organisms; the multiplicity of possible germs in the urine raised a doubt whether these were the actual cause of the disease or merely secondary invaders.

Whatever might be the original cause of the infection there was no doubt some congenital abnormality was responsible for some, at least, of the cases of persistent or intermittent pyuria. Dr. M. Woolstein, in 4900 post-mortems, had found congenital anomalies of the urinary tract in 117—2·5 per cent.—and Dr. W. P. H. Sheldon, in an analysis which he had made at Dr. Nabarro's request of 400 recent autopsies at the Hospital for Sick Children, Great Ormond-street, had obtained an identical percentage (2·5) of similar congenital abnormalities. Dr. Nabarro quoted several cases, which had been under the care of colleagues at Great Ormond-street, of recurrent pyuria and bacilluria in which after cystoscopy and pyelography some obstruction to the flow of urine was suspected and after being operated upon by Mr. Oswald Addison, and an aberrant vessel ligatured, each case had apparently been cured. Another cause of obstruction to the urinary outflow was the presence of a valve in the prostatic urethra to which Young, Frontz, and Baldwin first drew particular attention in 1919, and of which anomaly Drs. Poynton and Sheldon recently reported a series of 24 cases from the Great Ormond-street Hospital. The clinical diagnoses made in some of these cases had been pyelitis, renal infantilism, and idiopathic dilatation of the ureters, and an important practical point to bear in mind was that the true state of affairs might easily be overlooked if the whole genito-urinary tract were not removed in toto and subsequently carefully dissected out.

As regards treatment he agreed in the main with Dr. Wilkinson's remarks. In the administration of hexamine some experiments of Drs. Hare, Lepper, and Martland showed that two factors were of importance: (1) the secretion of an acid urine; and (2) the relative vulnerability of the invading bacillus to formaldehyde, in which form hexamine is excreted in an acid urine. Opinions still differed widely, as they did in 1910, as to the value of vaccines in the treatment of these cases. Dr. Nabarro referred to cases in which patients had done well with vaccines after other treatment had failed. He emphasised the importance of early cystoscopic investigation in cases which failed to clear up promptly, and advised the systematic investigation of those cases by a team—a physician, surgeon, bacteriologist, biochemist, and radiologist.

DISCUSSION.

Dr. H. F. HELMHOLZ (Rochester, Minn.) said that when he injected *B. coli* into the circulation focal infections did not, as a rule, follow, as they did when staphylococci or streptococci were injected. He had found that after intracystic injections of *B. coli* (in man and in animals) the urine rapidly cleared if the bladder were normal, but not if it were diseased. Cocci were more harmful to the kidneys than were *B. coli;* thus, 90 per cent. of the coccal injections produced renal lesions, whereas only 40 per cent. of the *B. coli* injections did so, and after injections of the two (either together or *B. coli* after cocci) only cocci were found in the urine. The renal pelvis, he stated, should be examined very soon (within two to three hours) after death, otherwise the cells desquamate, which gives rise to the "milky" urine found post mortem. In his opinion pelvic, in addition to renal, lesions did occur in cases of acute pyelitis, but the lesions heal very rapidly—in animals after 30 days and in a child 11 days old he had found the lesions healing. Experimentally he had found that making the urine acid after alkaline inhibited the growth of germs, and to acidify the urine he had used ammonium chloride and ammonium nitrate till the pH was 5 to 5·5. This allowed urotropine to be given in big doses even until the bladder was irritated or until the urine was sterile. He had seen chronic cases of even two to six years' duration clear up with proper urotropine treatment in a few days; failing improvement he would get a urologist to see the case. His results with hexyl-resorcinol were disappointing. As regards ætiology, Dr. Helmholz held that coli infection was "ascending" rather than hæmatogenous, but in the newly born it was more likely the latter, though

it was rare to find *B. coli* in the blood after the first week of life. It was possible to get *B. coli* in the blood without its occurrence in the urine, and coli infections, which in his opinion were commoner in girls than in boys, were often associated with gastro-intestinal upsets.

Dr. H. BRUCE CHOWN (Winnipeg) said he would limit his remarks to pyuria, as it occurred in infancy and in children with no obvious malformation of the urinary tract, and his conclusions were (1) that the lesion was commonly a bilateral suppurative interstitial nephritis, with occasionally pyelitis and rarely cystitis; (2) pyelitis seldom, if ever, occurred alone; (3) the *B. coli* usually reached the kidneys by the blood stream, occasionally in girls by the lower urinary tract; and (4) there was frequently an associated infection elsewhere in the body, due to another organism; (5) the condition was probably more common in girls than in boys in the proportion of about three to two. He opposed Dr. Wilkinson's view—as being but opinion unsupported by concrete facts—that the milder cases of the disease were a simple pyelitis and that those which came to autopsy and upon which Wilson and Schloss, Helmholz, and Chown himself had built up their pathology of it, were of a severe and unusual type. In his (Dr. Chown's) opinion much more work would have to be done experimentally before the bacteriological problem—whether the condition was due to *B. coli* or to cocci alone, or to both acting in association—was solved, but he was bound to admit that Dr. Helmholz's experimental results pointed against the coccal septicæmic origin of *B. coli* pyuria. He agreed with Dr. Helmholz as to the frequency of coli pyuria in the new-born child associated with a blood infection, and he referred to the fact that an exact counterpart of the condition occurred in new-born calves, which had either not received colostrum or received it late.

Dr. R. R. STRUTHERS (Montreal) said in his experience the condition was very rare in boys—he had had only two cases in boys and both had congenital anomalies.

Dr. HECTOR CAMERON (London) mentioned that pus and bacilli in the urine might be associated with other conditions—e.g., meningitis, and referred to the fact that clinically the case might have recovered, whilst the bacilluria persisted for months.

The PRESIDENT said that the discussion had left unanswered several questions: (1) Was there any relation between the pyelitis of infancy and that of pregnancy? (2) Why did it occur so commonly on the right side? We had heard about ascending and descending and hæmatogenous infections; could there also be a direct "horizontal" extension from the bowel as, for example, from an infected appendix? There was also a dietetic factor which needed explanation—namely, that cutting down the milk in these cases often benefited the patient.

REPLY.

Dr. WILKINSON said he still believed the ascending type of case to be the commonest—this might be called the clinician's case; next that of hæmatogenous origin, or the pathologist's case; and thirdly the chronic, which went to the physician and surgeon.

On the final day of the Section Dr. H. C. CAMERON opened a discussion on

Disorders of Sleep.

We know little or nothing, he said, of the physiology or pathology of sleep, so the subject must be approached from the clinical standpoint. He proposed to deal briefly with four examples of such disorders: (1) sleeplessness and continuous crying in young infants; (2) sleeplessness in older children; (3) night terrors; and (4) enuresis. Three factors might be concerned in the causation of the first—namely: (*a*) pain or discomfort; (*b*) inherited or constitutional neuropathy; and (*c*) faulty management. The pains of dyspepsia, whether they be intestinal colic or ærophagy with distension of the stomach, were by far the commonest causes of sleeplessness. To prevent "wind," sleep must be secured; to secure sleep, "wind" must be prevented, and Dr. Cameron had found that a grain of chloral hydrate given ten minutes before each of five or six feeds for some days would often be successful in preventing wind. It allowed the child's suction reflex to function normally in taking the breast. Nasal obstruction from catarrh was another common cause of nervous unrest; this might be effectively relieved by allowing a few drops of 1 in 5000 adrenalin solution to flow into the nostrils before the child is put to the breast. The neuropathic infant could usually be readily detected by his thin and tense face and rigid limbs; the expression was usually anxious and the child readily cried or frowned. A much commoner cause of sleeplessness, however, was faulty management of the child on the part of the nurse or mother. Such a child would often do very well in an institution or hospital, and if it must be with its mother then probably the best place for it was up against the mother's back, where the searchlight of the mother's face and eyes could not play upon the child and her hands were free to busy themselves in occupations which diverted her thoughts from the child. Dr. Cameron believed chloral to be the most satisfactory hypnotic in infancy and together with a hot bath and envelopment in a light woollen shawl instead of in swaddling clothes the best antidotes against restlessness. Sleeplessness in older children might also be due to over-anxiety on the part of the mother or other points of management, such as inadequate ventilation, a heavy meal taken late at night, lack of exercise, or over-fatigue.

Dr. Cameron went on to consider the disorders night terrors and enuresis, and pointed out these were probably associated with metabolic processes, notably the utilisation by the body of the carbohydrate reserves, and a disturbance of metabolism resulted in a fall in the blood-sugar, ketonæmia, and increased nitrogen excretion. Individual children differed widely in their reaction to ketonæmia and to the accompanying hypoglycæmia, and the "nervous" child, with its tendency to "turns" or "attacks," accompanied by vomiting, pyrexia, irritability, anorexia, or nausea and other allied symptoms, had a low fat tolerance, and the turns or bouts which the mother described were the physical and nervous manifestations of the underlying disturbance of metabolism. He referred to recent experiments by Salomonsen upon the reaction of young children to hypoglycæmia and ketonæmia induced experimentally by starvation and by a diet containing little sugar and a high fat content. The symptoms produced in the children were similar to these enumerated above under the "nervous" child, and the author was invariably able to predict which individual children would show a strongly marked reaction. The blood-sugar was normally at a low fasting level during the night and this would explain why certain disturbances, such as asthma, enuresis, sleep-walking, and night terrors would be induced in nervous or predisposed children. Acetone could often be smelt in the breath and Salomensen had found that the early morning urine contained the highest proportion of acetone. The sleep of certain children

with hypoglycæmia and ketonæmia always tended to be abnormal—confusion, muttering, restless movements—and enuresis might be considered a specific night terror. Very often it was the child who cared most who did it. Rest, wise and understanding management, and a diet rich in sugar and low in fats were the chief needs of the nervous child. In practice night terrors were often well controlled by glucose, but Dr. Cameron was unable to speak as confidently of the control of enuresis. In some inveterate cases he believed a true hysterical paresis of the sphincter developed which perpetuated the incontinence. In boys there sometimes occurred a concomitant incontinence of fæces which was hard and scybalous and escaped slowly through a sphincter which was toneless and paretic. As in the case of the sleepless, restless infant, so in that of the bed-wetting child it might be the over-anxious or apprehensive mother who was the cause of the perpetuation of the trouble and who needed management.

DISCUSSION.

Dr. R. F. RORKE (Winnipeg) said the new-born child needed 18 to 21 hours' sleep in the day; at two years a child should sleep 14 to 16 hours out of the 24. Sleep in these children was profound, so that noise did not rouse them. Infants who lack the sucking reflex cried a good deal unless the breast were soft and the nipple long; impatient children who were unable to get much milk also cried. In both these cases sleep was disturbed, as it also was in neuropathic infants. As a rule the child improved at three months of age or at the latest six months. It was important to reassure the mother that it was not her milk which was entirely at fault and also to secure her rest at night. Sometimes an improvement might be effected by cutting down the cream and butter, also the protein, in the mother's diet. A dose of castor oil given to the child at 4 P.M. followed by boiled water for 12–18 hours might do good. For mouth-breathers a tampon with liquid paraffin so that two or three drops trickled down each nostril was often efficacious, and early removal of adenoids was advisable. Diseases such as infections, otitis media, pyelitis, might interfere with rest and lead to sleeplessness.

Dr. A. H. SPOHN (Vancouver) said that pain and inherited neuropathy were important causes of sleeplessness. He had also seen disturbed sleep follow excesses of carbohydrates and condensed milk, though it might be the result of colic in these cases. Hereditary predisposition might play a part in the production of disturbed sleep and hypoglycæmia might be an associated condition. The parents should be examined and if necessary suggestions made for a readjustment of living and for the improvement of the home life. He was interested in the hysterical feature referred to by Dr. Cameron in enuresis. In Canada the drugs used were atropine and luminal, rather than chloral hydrate, as recommended by Dr. Cameron.

Dr. ALAN G. BROWN (Toronto) referred to the relation of thymus disease to these conditions. In many children who were restless by day and poor sleepers no cause could be found except an enlarged thymus by X ray. After treatment by one or two exposures to X ray there was marked relief and the same remark applied to children in whom adenoids were suspected but not found, only a turgescence of the mucous membrane and an enlarged thymus on taking an X ray of the chest. In the case of the neuropathic infant or, as they called it in Canada, the hypertonic infant, he had found that atropine relieved restlessness and brought about sleep. He did not agree with Dr. Rorke that castor oil was good for these babies.

Dr. N. R. RAWSON (Melita) referred to the treatment of enuresis by distension of the bladder and quoted 20 cases which were said to have been benefited thereby.

REPLY.

Dr. CAMERON said he agreed with Dr. Rorke about the difficulty with sleepless infants in tenement houses, when the disturbed neighbours knocked on the wall or ceiling. This made the unhappy mother still more agitated, who in turn would pass on her agitation to the infant, so that a vicious circle was thereby set up. He thought Dr. Spohn stressed the eugenic side more than he himself would do, for "nervousness" might occur in only one child in a family, and even then it might be transitory and due to a transitory cause. Answering Dr. Brown, he said we in England did not see large thymuses so frequently as they appeared to do in Canada and that aspect in the causation of restlessness was new to him. His genito-urinary colleague at Guy's Hospital had had some success in the treatment of enuresis by bladder distension, but he (Dr. Cameron) thought the effect was largely psychological, as his colleague was a very "persuasive" man. Glucose might help in night terrors and to a less extent in enuresis; ovaltine and other similar foods might produce sleep.

Artificial Sunlight.

Dr. A. EIDINOW (London), whose paper was summarised and read by Dr. Alan Brown, gave a historical survey and review of the physiology of light therapy, with a description of the apparatus used, the indications and contra-indications for treatment. The results of light treatment, as of exposure of the body to the sun and open air, included: (1) increased warmth of the body; (2) vasodilatation and increased blood flow; (3) increased transudation of lymph; (4) increased metabolism; (5) stimulation of heat regulating mechanism; (6) analgesic and sedative effects; and (7) increasing resistance to infection. Ultra-violet radiations might be applied in one of four ways: exposure of normal skin to sources of light, exposure of ulcers or other diseased tissues to a focused beam of light, the oral administration or injection of irradiated drugs, foods, or tissue extracts, &c. The reaction of the skin depends on the following important conditions: the intensity of radiation, the character of the wave-length of rays, the time of exposure, distance from source of light, the sensitivity of the patient's skin, and the area of skin exposed. He distinguished two methods of technique in treatment—the long-ray and the short-ray therapy—the former included sunshine and skyshine as used in the treatment of surgical tuberculosis. This was the principle of the Finsen light treatment, which had been in use for over 20 years and given good results in debility and tubercle. No importance was attached to skin reactions such as erythema, but pigmentation finally developed. He described his new "daylight" lamp, so called because the rays were similar to daylight, to which patients might be exposed for hours and might even sleep under with advantage in cases of tubercle and debility. Animals exposed to the lamp have shown increased resistance to infection, and its rays have also antirachitic and bactericidal properties. Long-ray therapy was contra-indicated in acute pyrexial disease and in septicæmia or toxæmia, but during convalescence it should prove useful.

For short-ray therapy the lamps used were

tungsten arc, long-flame arc lamps containing metallic cord carbons, and quartz mercury-vapour lamps. Short rays produced rapid erythema and Dr. Eidinow gave detailed conclusions from his own observations upon the use of these rays, for he had found that the greatest errors in radiation therapy had resulted from confusion in the use of ultra-violet radiations. The technique of short-ray therapy should be strictly controlled and be done by an expert. The types of cases which responded to short-ray therapy were general debility, secondary anæmia, subacute and chronic tuberculous disease of lymphatic glands, lungs, and mucous membranes, asthma, subacute and chronic inflammatory diseases of the eyes, eczema, acne, alopecia, staphylococcal skin infections, rickets, and osteoporosis. On the other hand, rheumatic conditions, such as arthritis, fibrositis, and neuritis, responded more favourably to long-ray therapy. There were no specific laboratory methods to determine the index of reaction of the body to radiation; each case must finally be judged from the clinical evidence. Advanced heart disease, arterio-sclerosis, high fever with intoxication, nervous irritability, and impairment of the renal functions were the chief contra-indications to radiation therapy. The greatest advance in radiation therapy followed the discovery of the antirachitic properties of ultra-violet rays. These have been shown to be due to a photo-chemical reaction by which ergosterol is irradiated and transformed into vitamin D. This was absorbed by the capillaries of the skin and so distributed in the body, where it produced its beneficial effects. Similar results could be obtained by the oral administration of irradiated ergosterol. He had also concluded from his observations that ultra-violet rays absorbed by living cells produced a bactericidal effect locally at the site of irradiation, which led to an increased bactericidal power of the blood. The growth of plants depended upon the vital functions of the rays of the sun, and our existence was indirectly controlled in the same way, for there was ample evidence that these rays had great influence on our mechanism to immunity, resistance to infection, growth, and tissue metabolism.

DISCUSSION.

Dr. ALAN BROWN said there was little to criticise in Dr. Eidinow's paper, and the work which he and his colleagues had carried out in Toronto fully bore out Dr. Eidinow's conclusions except that they had very little experience of local therapy with the quartz mercury-vapour lamp, as lupus did not occur in Canada. Light therapy certainly increased the resistance to disease and Dr. Robertson had found that the resistance of irradiated rats to a particular germ was 600 times greater than that of non-irradiated rats. Dr. Brown had found that artificial light applied during November and again in February was very beneficial for the prevention of colds. Dr. Eidinow had made no reference to the effect of these rays on digestion, but, in conjunction with Dr. Price, of Calgary, he (Dr. Brown) had found that by irradiation the digestion of children was improved. Sunshine was more useful than the artificial light from lamps, but at the latitude of Toronto the invisible or chemical rays were effective only from the early part of March till early in October. Skyshine was also beneficial (about half to two-thirds as good as sunshine) for rickets could be prevented or healed by it. They had carried out many experiments in Toronto with vitamins by charging cereals with vitaman D and had had beneficial results in children and experimental animals. It required 100,000 units of vitamin D to produce an overdose, so that treatment by this vitamin could not easily be overdone.

Prof. H. B. CUSHING (Montreal) said that in Montreal and other cities in temperate climates contagious diseases, other than typhoid and dysentery, were practically non-existent during the months of May, June, and July and in his opinion the explanation was to be found in the greater amount of sunlight which prevailed during those months. This acted either by destroying the germs of these diseases or by raising the patient's resistance. We might be able ultimately to eradicate acute respiratory diseases by installing artificial sunlight lamps in our living rooms, schools, &c

Dr. NABARRO referred to observations made with milk irradiated by a simple method devised by Mr. J. O. Hickman whereby the taste of the milk was unaffected and the vitamin D content greatly increased. Such milk led to a considerably greater rate of growth in normal children than did non-irradiated milk; it often gave the necessary fillip to debilitated children who reached a certain stage of nutrition or of convalescence and then did not improve, and it also appeared to increase the resistance to catarrhal conditions, such as the common cold.

Dr. H. CHODAK GREGORY (London) said that children certainly improved under skyshine and asked if a cloudy condition of sky made any great difference in the effect produced.

Prof. W. E. DIXON (Cambridge) expressed the opinion that we might have too much light, as of most good things. People living in the tropics often avoided the light as much as possible. Many other ways of raising the resistance to disease were known; the late Dr. Washbourne showed that the injection of water into animals would do it, and Abrams's box would do the same; it was largely a psychological problem.

Dr. HUTCHISON said he came to the meeting a sceptic, but after all he had heard he was converted; he was, however, surprised that no speaker had referred to the experiments conducted by the Medical Research Council which seemed to show that children exposed to artificial sunlight were not benefited.

REPLY.

Dr. ALAN BROWN, in reply, said that the value of skyshine was one half to two-thirds that of sunshine, according to the presence or absence of clouds. Animals did well under skyshine. Pigmentation was protective but was not essential, for rickets could be cured without it. Two hours per day was the maximum duration of exposure allowable; this could be between 11 and 1, except in summer when the exposure should be in the morning between 9 and 10 and in the afternoon from 4 to 5 or 5 to 6.

BRIGHTON SANATORIUM: NEW MAIDS' HOME.—On Oct. 15th the Mayor of Brighton opened the new maids' home at this large borough institution, which has been erected at a cost of over £7000 to meet the wishes of the Health Ministry. Great difficulty had been experienced for many years in retaining maids and nurses at the sanatorium, largely owing to the absence of proper provision for their sleeping, rest, and leisure hours. Dr. Duncan Forbes, medical officer of health, explained the advantages of the new home, and the consequent rearrangement of the various wards which was now possible. He said that probably in no similar institution in England was such a variety of work undertaken. Some £70,000 had been spent upon the sanatorium since it was hurriedly conceived and started with a few wooden buildings in 1881.

MEDICAL SOCIETIES

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

AT a meeting of this Association, held on Oct. 21st, Dr. LETITIA FAIRFIELD gave her presidential address on

The Effects in Medical Practice of the Local Government Act, 1929.

She pointed out that the present organisation of the Public Health Services can be traced back to very varied sources, and these remote origins still determine their composition. First came the poor-law, which, although instituted in 1601 with the express duty of caring for the destitute sick as part of its function, had made no suitable hospital provision of any kind when the Guardians of the Poor took over its administration in 1830. The very fine, if unequal, service handed over to the Public Health authorities on April 1st, 1930, was thus entirely the work of the last 96 years. The Public Health Service proper was much younger as it derived from the General Board of Health, founded in 1848. So great was then the fear of bureaucracy and centralised control that for 25 years the Board was not allowed jurisdiction of any kind in an area unless the death-rate was over 23 per 1000. Dr. Fairfield said that the success of the operations of the Board in protecting the public against local vested interests was probably the secret of its rapid growth as compared with other authorities. Modern discoveries in medicine extending the range of knowledge of infectious disease, the new conceptions of preventive medicine, which gave birth to the school medical service, and the maternity and child welfare movement, all contributed to extend the domain of the medical officer of health. When the chaos of administrative effort had become impossible to overlook, and the shortcomings of the guardians, as a body, for administering treatment were likewise the subject of comment by a Royal Commission, it was, naturally, the medical officer of health who was entrusted with the organisation of a united service which would place the full resources of medical science at the disposal of the people of the country.

Dr. Fairfield drew attention to the fact that the poor-law had not been and could not be abolished, for it conferred important rights as well as imposed restrictions. The poor-law stood between the poor man and death from starvation and neglect in illness; it gave him a statutory claim on the pockets of his fellow-citizens, and this obligation could not be handed over to the caprices of charity or the vagaries of municipal policy—which might give much more, but might give nothing at all. If and when the transferred infirmaries were administered under the Public Health Act, the obligation to treat every destitute applicant would remain. In London the Public Health Committee took over from the old Boards of Guardians 29 infirmaries, comprising 16,500 beds, and 14 allied institutions with 11,500 beds in addition to 34 special hospitals (fevers and children's, &c.) totalling 15,000 beds. The L.C.C. was now, moreover, responsible for domiciliary treatment of the sick poor and for medical care of the chronic sick, the aged and infirm, and of over 8000 children in the former poor-law schools. The staffing of the transferred hospitals was giving rise to much controversy throughout the country, and experiments in several methods would probably be worked out. Some authorities might prefer to develop on the lines of a whole-time service as in the R.A.M.C., with room for specialisation and research, others would follow the model of the voluntary hospitals and rely on visiting consultants, while in rural areas it was suggested that general practitioners might have a considerable share in the work. The improvement of domiciliary medical treatment was also admitted to be of great importance. Dr. Fairfield pointed out that not all the sick poor needed to be treated in hospital, and institutional treatment of an adequate kind was now so costly that in her view no beds should be occupied if the patients could be dealt with in their own homes.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society on Oct. 22nd, with Prof. GRAHAM SIMPSON, the President, in the chair, Mr. A. S. PARKES, D.Sc., Beit Memorial Research Fellow at University College, London, read a paper on the

Regulation of the Ovarian Cycle.

Various lines of work, he said, all tended to show that the activity of the ovary was regulated from some external source. It was found many years ago that the ovary of an immature animal grafted into an oöphorectomised adult female immediately underwent development and began its morphological and endocrine cycle long before it would have done so in its original environment. This and similar observations demonstrated quite clearly that the functional age of the ovary was regulated by that of the soma. It was now well known that the number of follicles ovulating at a time was governed, not by the amount of ovarian tissue present, but by the amount available of some substance in the circulating blood. Periodic action of the œstrus-producing hormone could also be demonstrated after complete elimination of the cyclic structures of the ovary by exposure to X rays. The periodic mechanism, whatever it might be, was thus probably located elsewhere than in the ovary.

Experimental work during the last few years had revealed an amazing mechanism whereby substances elaborated by the anterior lobe of the pituitary body activated the ovary. One of the anterior lobe substances was concerned in the maturation of the Graafian follicle and ovulation, while another was responsible for causing the formation of the corpus luteum from the shell of the ruptured follicle. The "luteinising" substance administered to an animal with a quiescent ovary caused the follicular granulosa to undergo luteinisation without the intermediate act of ovulation. The other substance caused the quiescent ovary to enter upon a phase of follicular maturation culminating in ovulation and the formation of the corpora lutea. In each case changes were observed in the accessory organs corresponding to the phase induced in the ovary and resulting from the stimulation of ovarian endocrine activity. The action of the substances was exerted solely on the ovary and thence on the accessory organs. Anterior lobe preparations had no effect in animals whose ovaries had been removed.

The discovery of the anterior pituitary substance had explained the nature of the stimuli responsible for evoking the different phases of ovarian morphological and endocrine activity, but little progress had been made in elucidating the means whereby the periodic activity of the anterior lobe hormones was organised. Presumably some kind of endocrine cycle existed in the anterior lobe, but attempts to obtain histological evidence of this had so far been abortive. In any case, whatever the cycle mechanism in the anterior lobe might be, it was necessary to suppose that it could be modified by such events in the accessory organs as pregnancy, during which prolonged luteal activity was found.

REVIEWS AND NOTICES OF BOOKS

Insomnia.

By H. CRICHTON-MILLER, M.A., M.D., Hon. Director, Tavistock-square Clinic. London: Edward Arnold and Co. 1930. Pp. 172. 10*s.* 6*d.*

OF recent years modern psychology and psychotherapy have made valuable contributions to the ætiology and treatment of sleeplessness. Nevertheless, we are still far from having reached a complete explanation of the physiology of sleep and a satisfactory solution of the problems of insomnia. This volume, described as "an outline for the practitioner" makes no claim to be an exhaustive study of the subject of sleep and its disorders, but rather to present to the busy practitioner some of the more important aspects of insomnia and thus to introduce him to the wider problem of the psychoneuroses. The more general considerations are dealt with in the first section of the book; the various definitions of sleep are mentioned and its nature and mechanism are briefly discussed. The factor of emotional conflict is rightly emphasised and various conclusions are reached, as, for instance, that "insomnia is a failure to achieve a normal degree of that state of minimal activity of mind and body which we call sleep"; that it consists in an interruption of the mechanism, as yet unfathomed, which regulates dissociation; and that sleeplessness is a manifestation of "insecurity."

The chapter dealing with treatment contains much sound and practical advice. The author points out the fact, which is only too true, that the usual therapeutic attitude to insomnia is an endeavour to induce sleep by alterations of environment rather than to treat the insomnia; that is, by attempting to adjust surroundings to the patient instead of trying to educate the patient up to his environment. Massage, muscular relaxation, the elimination of toxic factors, digestive disturbance, occupation, and especially the patient's attitude to his symptom, all have their place in treatment. We ourselves know of no way to diagnose "adrenal instability."

The various theories concerning the mechanism of sleep, which are numerous and often contradictory, do not all deserve the space allotted to them. Pavlov regards internal inhibition and sleep as one and the same thing and his work on condition reflexes is well summarised. From the psychological aspect, dissociation, dreams, and hypnosis are discussed in their relation to sleep and the views of different psychological schools, notably those of Freud and Jung, are reviewed with regard to the psychoneuroses. The form of psychotherapy which, in the author's experience, appears to have given the most favourable results, is one which might be termed "psychological exploration" rather than analysis. Hypnosis is also advocated for certain cases and especially for those not sufficiently intelligent to coöperate in other forms of psychotherapy. In a section dealing with the medicinal treatment of insomnia the author shows a preference for luminal given two hours before sleep is required, with Liq. Brom. Chlor. Co. (B.P.C.) taken at bedtime, the dose of each preparation varying with the severity of the case. The book closes with a chapter containing descriptions of nine illustrative cases, the patients having complained of insomnia with or without other features. These cases are not complete clinical pictures but are intended to serve merely as typical problems in diagnosis and treatment.

The style of presentation is occasionally involved. The work, however, is to be cordially recommended for the purpose for which it is intended—as an outline for the practitioner. It also serves as an admirable introduction and up-to-date review of a difficult subject. There is an excellent bibliography.

Modern Otology.

By JOSEPH CLARENCE KEELER, M.D., F.A.C.S., Associate Professor of Otology, Jefferson Medical College. Philadelphia: F. A. Davis Company. 1930. Pp. 858. $10.

THIS large text-book on otology reflects the extensive experience of its author, but is incomplete in certain respects, and in others not very well arranged. For example, the subject of vestibular tests is discussed early in the book under physiology, and again at greater length in a later chapter on diseases of the internal ear. This makes for redundancy, and in neither place is the practical application of this intricate matter so set out as to enable the practitioner to carry out, and to make proper deductions from, these tests; and an important mistake is made when it is stated that douching the right ear with cold water produces nystagmus to the right side. Although no direct treatment is of avail in otosclerosis, attention to concurrent anæmia or endocrine disturbance is of some value, and there are combined cases in which the local treatment of catarrhal conditions are helpful; these matters might usefully have been discussed. Again, in the section on aural furunculosis, general treatment receives no mention.

For the rest, Prof. Keeler's views, founded on his personal experience, will be read with interest. In acute otitis he favours routine syringing after paracentesis; in his opinion spontaneous perforation of the drum is usually of insufficient size, frequently heals prematurely while the ear is still suppurating, and should usually be enlarged. In dealing with the indications for operation in acute mastoiditis, he states that operation should be performed without delay whenever tenderness can be easily elicited; this dictum takes no account of the stage of the disease when the symptom occurs, and is contrary to the general opinion that mastoid tenderness is very common in the early days of any acute otitis. In the performance of the mastoid operation he considers exposure of the dura mater in the middle fossa a very serious accident. He recommends ligation of the jugular vein before any intervention on the lateral sinus. After antrotomy, or the Schwartz operation for acute mastoiditis, the wound is packed

until the cavity is completely closed, the time required being eight to ten weeks. This operation is described in the chapter on chronic mastoiditis, and the indications for the two types of operation are not very clearly given.

This work well illustrates the difficulty of compiling well-balanced text-books. The author states in the preface that he undertook the task of its preparation because he had always felt existing text-books to be unsatisfactory; but in spite of his obvious sincerity of outlook, his attempt to improve over many predecessors is not really successful.

Treatise on Materia Medica and Therapeutics.

By the late RAKHALDAS GHOSH. Twelfth edition. By BIRENDRA NATH GHOSH, F.R.F.P. & S. Glasg., Examiner in Pharmacology, University of Calcutta and State Medical Faculty of Bengal. Calcutta: Hilton and Co. London: H. K. Lewis and Co., Ltd. 1930. Pp. 763. 12*s.* 6*d.*

THIS work has been thoroughly revised in the light of recent investigations, a good many of the less important drugs have been deleted, and a number which are popular at the moment, such as sanocrysin, novasurol, tryparsamide, and ephedrine have been introduced. We have here a clear account of present-day knowledge of materia medica and therapeutics, and the work should continue to merit the great popularity it enjoys among Indian students of medicine.

Surgical Diseases of the Thyroid Gland.

By E. M. ROBERTS, M.D., Associate Professor of Surgery, McGill University; R. R. FITZGERALD, M.D.; and P. G. SILVER, M.D. Philadelphia: Lea and Febiger. Pp. 238. $3.50.

THIS book in small compass presents the surgical aspect of the goitre question succinctly, accurately, and in an attractive and readable fashion. The account is founded upon the study of 700 patients who have passed through the goitre department of the Montreal General Hospital. The care with which the work has been carried out is obvious and lends weight to the authors' statements and opinions. We would select for special mention the sections on exophthalmic goitre and the discussion on the ætiology of thyroid enlargements. The book is very well written (except that occasionally the author uses a clumsy adjective such as "goitrigenous"), and well printed and illustrated. It should be read by all surgeons interested in goitre.

Recent Advances in Analytical Chemistry.

Vol. I.: *Organic.* Edited by C. AINSWORTH MITCHELL, M.A., D.Sc., F.I.C. London: J. and A. Churchill. 1930. Pp. 421. 12*s.* 6*d.*

THE biological worker is often forced to waste time in searching the literature for methods of analysis suitable to a given problem; not only are many of the most significant advances published in industrial journals which are not readily accessible to him, but also he is often quite unable to assess the true value of the various contributions to the mass of new methods and improvements published every year. This critical summary of the advance in analytical methods during the last ten years will give him much help. Each chapter deals with the special analyses demanded in the various industries, such as sugar, oils and fats, milk and milk products, gas analysis; and each chapter is written by an authority whose work fits him peculiarly for the task. Among these specialised analyses the research worker will find hints which will enable him to devise methods for his own problems. Dr. Dorothy Jordan Lloyd contributes a chapter on the analysis and determination of the constitution of the proteins. The inclusion of descriptions of physico-chemical determinations, of methods of biological assay, of the use of enzymes as an aid to analysis and of physiological methods is unusual in a book on chemical analysis and will give great satisfaction. It is to be regretted that the authors do not set out the results of their own experience to a greater extent, for practical hints in technique are more needed in analysis than in any other branch of chemistry.

In addition to the large number of references, an adequate bibliography is supplied at the end of each chapter. The publication of the second (inorganic) volume will be eagerly awaited.

Cosmetic Treatment of Skin Complaints.

By Prof. E. KROMAYER, Berlin. London: Humphrey Milford, Oxford University Press. 1930. Pp. 110. 6*s.* 6*d.*

THE German original of this translation was recently reviewed in this journal, and the comments there expressed may be taken to apply to the English version. The translator's identity is not revealed, but the work has been well done. The illustrations are identical with those of the second German edition (1929). Prof. Kromayer, whose fame in the realm of actinotherapy will rank next with that of Finsen, is admirably qualified for the task he undertakes in this small manual. His recommendations, although they may not entirely commend themselves to those with strictly dermatological experience, are deserving of the most careful consideration. This applies in particular to the specialised procedures with rotary instruments—the burr or rasp, and the cylindrical knife. Without a practical demonstration of the method or its results an exact opinion is not possible. The principle involved is simple, and aims at removing stigmata of all kinds from the epidermis, with a minimum of damage to the underlying cutis, injury to which inevitably leads to scarring. Among common conditions in which the author recommends the procedure are boils (cylindrical knife or punch), comedones (rasp or drill), acne abscesses (punch), megaloporia (rasp), and freckles (rasp). The removal of so delicate a lesion as a freckle with such an instrument as a rasp would seem to require a delicacy of touch given to few. It must be remembered, however, that the pigment-forming cells are situated in the basal cell layer of the Malpighian rete, where caustics, if they penetrate at all, might destroy too much and give rise to hypertrophic scars. It is satisfactory to note that the X ray treatment of hypertrichosis is condemned, although it is difficult to see, without a practical demonstration, how the method of cutting out hairs with a cylindrical punch, 8 mm. in diameter, can be superior under any circumstances to electrolysis. The prescriptions are all simple and based on classical formulæ, but the most valuable sections of the book are those dealing with the indications and technique of the famous Kromayer lamp, which since its introduction over 30 years ago has not been excelled in its special dermatological field, and has undergone but few mechanical modifications.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 8, 1930.

THE POSITION OF NURSING.

A LETTER by Dr. E. CARLING, published in these columns on Oct. 11th, set out the difficulties of recruiting for the calling of nursing, emphasising the fact that nursing does not any longer attract enough young women having the proper educational standard. There is a twofold position to consider—first, the enlisting of probationers, and, secondly, the conditions of service offered to trained nurses; and we felt that THE LANCET would be discharging an appropriate duty by arranging for a Commission of Inquiry that would assist in the devising of practical remedies for conditions which affect the sick throughout the country. The composition of that Commission is nearly complete. It will consist of members of the medical and nursing professions, and of persons in a position to know the educational and economic issues involved. The names of the Commission will be published shortly. While delegates from official bodies have not been invited to join the Commission, that body will count upon their sympathetic coöperation.

THE PUBLIC HEALTH.

EARLY this week Sir GEORGE NEWMAN issued his survey[1] of the public health during 1929. The report, as he is careful to point out, is not a scientific text-book. Avoiding technicalities and details of research it presents the established elements of knowledge essential to the guidance of the authorities in their business of providing for the health of the people in their charge. The medical department of the Ministry of Health over which Sir GEORGE NEWMAN presides is itself a complex organism. Separate departments deal specially with (1) infectious disease; (2) maternal and child welfare; (3) tuberculosis and venereal disease; (4) food and drugs; (5) general practitioner services; and the activities of the whole may be compared to those of a five-rayed asterid, each arm of which is activated by numberless podia, and with a single coördinating madreporite situated near the middle of the central body. The population surveyed comprises nearly 45 million persons among whom, owing to declining birth- and death-rates, the proportion of children is decreasing and the proportion of persons past the prime of life increasing, with the result that the average age of the population is steadily rising and medical interest centres more and more on middle age. The principal causes of death occur in the same order of precedence as last year, with certain minor variations. Among every thousand recorded deaths 225 are due to diseases of heart and circulation, 157 to bronchitis, pneumonia, and other respiratory diseases, 107 to cancer and other malignant disease, 82 to diseases of the nervous system, and 71 to tuberculosis in its varying forms. The corresponding figure for influenza is 55, for the outbreak in the early part of the year was the most severe from which the country has suffered since 1918. Tuberculosis, nervous diseases, malignant diseases, and premature birth all show a proportionate decline in death certification, while respiratory diseases, including bronchitis and pneumonia, have increased as a result of complications of this kind which accompany influenza. Sir GEORGE regards it as both encouraging and gratifying to find so relatively sound a condition of health among the English people at the present time. It is, of course, not possible to estimate the incidence of sickness which is not fatal, but there is no reason to doubt the general lessons of a sample table given in last year's report showing that among a thousand insured persons in receipt of medical benefit, 208 were suffering from respiratory disease, followed in diminishing frequency by abnormalities and irregularities of the digestive system (122), rheumatic disorders (82), debility, neuralgia, and headache (81), abscesses and septic conditions (74), with diseases of the nervous system following some way behind. Such a category is clearly of the roughest sort. What conditions can be classified with exactness as rheumatic must vary with the meaning that is attributed to the term rheumatic, while debility and neuralgia in association with headache form a still vaguer picture. But any closer classification would substitute error for uncertainty.

During the year no important epidemic of disease, other than influenza, occurred to upset the normal routine of health administration. The incidence and mortality of enteric fever again decreased, while those of scarlet fever increased somewhat; it is satisfactory to note that the incidence and mortality of encephalitis lethargica, which in the past have closely followed those of influenza, have not done so this year. The absence of disturbing elements has made it easier to observe the slow quiet progress in dealing with some disorders of childhood which have almost come to be accepted as untouchable by medical endeavour. During the year measles accounted for 3388 deaths, the greatest number from any of the infectious diseases of childhood, but for the first time local authorities are beginning to use the serum of convalescents to protect children who have been exposed to infection. The method is almost contemptible in its simplicity, and on page 83 are printed, side by side, two little cautionary stories of the medical officer who did and the one who didn't. A single adult, it seems, may provide as many as 20–50 protective doses, and it is not even necessary to go outside the ranks

[1] On the State of the Public Health. Annual Report of the Chief Medical Officer to the Ministry of Health for the Year 1929. H.M. Stationery Office. Pp. 240. 3*s*. 6*d*.

of the health department to obtain the material for immunisation. In other infections the immunising principle is also gaining ground. Children are being protected against diphtheria in clinics and at school by 37 authorities who have obtained the necessary sanction; the cost of immunising a batch of 150 children may be less than that of treating a single case of established disease. In one district the showing of a persuasive film made it necessary to open five clinics a week instead of one. In scarlet fever antitoxin treatment is justified even in mild cases by the more rapid recovery of the patient and the lessened tendency to complications. Similar methods are being tried for infectious diseases of the nervous system whose record of mortality is still of the same order of importance as the numerically more impressive zymotic diseases. While poliomyelitis has increased a little and encephalitis lethargica has declined, our ignorance of the epidemiology of these two diseases is frankly admitted.

The event of the year in public health administration has, of course, been the passing of the Local Government Act and the changes consequent thereupon. Unfortunately, it is difficult for anyone unacquainted with official modes of speech to visualise what exactly is happening even in the lucid pages of this report. It is noted that 16 out of 62 county councils and 49 out of 83 county borough councils have formally abrogated their powers of dealing under the Poor-law Act with some of their medical services, which will henceforth be performed exclusively under health committees. There are other ways in which health services can be unified under the new legislation. For instance, 7 county and 21 county borough councils have assigned to some particular committee, other than the public assistance committee, the domiciliary relief of expectant and nursing mothers; 7 and 11 respectively have done the same in regard to mentally defective persons. Outdoor medical relief has been assigned to the health committee by 7 councils and the maintenance of poor children to the education committee by 31 other bodies. Apart from such formal transference, the gradual absorption of poor-law medical functions will be largely aided by means of the normal administrative machinery of the local authority. There is an interesting passage in this section of the report dealing with the sick-wards of the late poor-law hospitals and institutions. Some of those responsible for the care of the bedrid infirm have advanced reasons why it is preferable for many persons now being maintained in the hospital to be cared for in appropriate wards in the "house." The care and attendance they require is there given more consistently by women skilled in this work than by rapidly changing groups of probationers in training, even under the direction of a nursing sister, while the routine of these wards can be better adjusted to secure a homely atmosphere of comfort for the old people. Should they develop acute illness or be recognised as in need of treatment they can be quickly transferred to an acute hospital ward. This is an interesting point of view.

In his concluding paragraph Sir GEORGE has a kind word to say for the newspaper press as the most effective means of educating people on the importance of health, if only when acting as interpreters their interpretation is true and educative rather than propagandist.

TRANSMISSION OF MENTAL DEFECT.

THE statement that 80 per cent. of mental deficiency is hereditary is often taken to mean that the majority of certifiably mentally defective children are offspring of certifiably mentally defective parents, or at least that many defective members will be found in their families. In fact, this estimate includes many cases in which a familial psychopathic strain is deduced from abnormalities among collaterals such as uncles and aunts. The question of direct transmission has been the subject of a small investigation by Dr. A. C. WILLIAMS, and his results are given in the annual report of the School Medical Officer for London. On the statements of teachers, social workers, and the like, he classifies the parents of 100 children admitted to special mental defective (M.D.) schools into five groups: (1) superior, (2) average, (3) inferior, (4) unstable, and (5) mentally defective. By "superior" he seems merely to mean above the average for the district, and he uses similar criteria for "average" and "inferior." "Unstable" covers the criminal and alcoholic, while "mentally defective" includes only those who have been at some time certified or have been pupils of an M.D. school. The M.D. school examinations in London have been going on for so many years that most of the mentally defective under middle age would be caught in this sieve, though not quite all. The status of the parents he gives as follows: superior, 15; average, 45; inferior, 28; unstable, 8; and M.D., 4. The high figure for the "superior" group is somewhat surprising, and the percentage of parents proved to be mentally defective is small, especially as the cases included all those where either father or mother was mentally defective. But since many (perhaps half) of the parents would have missed the school "sieve" because of their age, or for other reasons, it is likely that the figure 4 would be increased considerably, perhaps nearly doubled, in an ideally complete investigation. While the inferior and unstable parents are together given a total of 36 per cent., it is added that "some may have been classed as 'average' owing to paucity of information, and it is probable that this figure should be raised to nearly 50." The modifications in these figures detract from their value, but their significance is increased by the results which Dr. WILLIAMS obtained from an independent group of 66 families of which the headmistress of an M.D. school had accurate knowledge. These figures tallied remarkably closely with those given above, the mentally defective parents being 5 per cent. and the inferior and unstable 32 per cent. Further-

more, the results are curiously in harmony with those of an inquiry by the Birmingham After-Care Committee, which noted the mental condition of 276 children, all of whom had a parent who had attended a special M.D. school. Of these children, 250 were attending ordinary schools, 12 were at work (one being M.D.), 8 were physically defective, and 6 were M.D. Thus, in all, there were 7 cases of mental deficiency, or rather less than 3 per cent. All these children were over 5, but many of them were under 7, and so would have missed examination—that is to say, the true percentage was higher, perhaps 5 or 6 per cent.

For a study of this kind the ideal would be to have direct mental examination of large numbers of children, of their parents, and their grandparents. This is, of course, impossible, and all that can be said at present is that the proportion of direct transmission from certifiable parent to certifiable child is very small, probably between 5 and 10 per cent., the majority of defectives being the offspring of persons not themselves certifiable but of inferior or unstable mentally. Dr. A. F. TREDGOLD says that his observations show that "in relation to the total number of defectives, the proportion of those who are the offspring of a certifiably defective parent or parents is extremely small."[1] Dr. WILLIAMS also classified the status of the parents of a small group of imbeciles, and the results showed the feature noted by Dr. E. O. LEWIS, that defectives of the lowest grade are often the children of persons of normal or even superior intellectual capacity. This phenomenon may be at least partly accounted for by the fact that many of these children are cases of secondary amentia (if mongols are included under that heading).

In the same report is given Dr. F. C. SHRUBSALL'S analysis of the records of 1360 cases dealt with under the Mental Deficiency Act, in which detailed inquiries were made into the family. In this important series it was found that in 9·5 per cent. one or more of the brothers and sisters were also mentally defective (though in nearly 1 per cent. a sibling had won a scholarship) and it was remarkable that the frequency varied inversely with the grade of defect; that is, the feeble-minded had defective siblings in 11·6 per cent., imbeciles in 5·7 per cent., and idiots in only 4·3 per cent. Dr. SHRUBSALL remarks that "in all but seven of the instances in which more members than one of the sibship were mentally defective, the type of defect found was simple primary amentia, often of the sub-cultural variety," and the greater proportion of defective siblings in this type and the highest grade was illustrated by an earlier analysis (in 1912) by Dr. SHRUBSALL of the records of 2000 ex-pupils of M.D. schools—that is, educable mentally defectives—for here the figures were 13 per cent. The much smaller influence of heredity in low-grade cases is also noted in Dr. LEWIS'S investigation for the Joint Committee, but the terms of reference did not include transmission in general. It seems highly desirable that an authoritative inquiry should be held into the causation and prevention of mental defect—a recommendation already made by the medical committee of the Central Association for Mental Welfare.

[1] Mental Welfare, Jan. 15th, 1930, p. 10.

A NATIVE MEDICAL SERVICE FOR SOUTH AFRICA.

IN the report of the Hospital Survey Committee of South Africa, in 1927, it was pointed out that there was approximately only one hospital bed for every 2231 non-Europeans in the Union, and that medical and nursing services were not available for natives living under tribal conditions, except at a few centres. It is not surprising that the witch doctor flourishes among the tribes, and that in Natal native herbalists are licensed by the State at £3 per head per annum. The Committee recommended the establishment of a Government medical service consisting of whole-time medical practitioners, nurses, and health assistants. It is suggested that the health assistants shall be natives who have reached a definite standard of proficiency in male nursing, the recognition of infectious disease, deverminisation of huts, clothes, and persons, and the systematic treatment of malaria and venereal disease; it is not intended, however, that they should undertake anything in the nature of medical practice. The Committee further proposed that the scheme should be run in connexion with Government or mission hospitals wherever possible, to avoid the expense of building new quarters, but the cost would in any case be high. Ultimately, it is intended that medical service shall be supplied by native practitioners, who will not only be more acceptable to the patients, but who can be engaged at salaries lower than those likely to attract Europeans. Unfortunately, there are not yet a sufficient number of native practitioners available, and it is contemplated that inducements might be offered to natives to qualify as medical men, such inducements to take the form of loans and bursaries. Additional expenditure on buildings for training and for hostels would increase the initial cost considerably. Experience, however, in other parts of Africa suggests that the native practitioner, when qualified, is not often content to practise in his home surroundings.

There are several objections to the scheme, other than the financial aspect, which have been stressed[1] by Sir EDWARD THORNTON on behalf of the Union Public Health Department. If put into practice, he writes, the scheme would inevitably affect the livelihood of European practitioners at present working among natives; it is even probable that certain sections of the European population would desert their own doctor for one whom they fancied combined a knowledge of medicine with the art of witchcraft. Nor is it very likely that native practitioners will be content to practise in the bush when it lay in their power to migrate to the towns. Col. THORNTON has an alternative suggestion, which, although he admits it to be less sympathetic to native aspirations than that proposed by the Committee,

[1] Journal of the Medical Association of South Africa, Sept. 13th, p. 507.

would go a long way towards meeting the urgent needs of the native population, or so he believes. He proposes that the European district surgeon should be made the head of the organisation in his area, and should be responsible for supervision of the health centres. Male natives should be trained as health assistants, and females as nursing aids, to carry on their work under the direction of the district surgeon. The ultimate aim would be the revocation of licences issued to untrained native practitioners, and the abolition of practice by native medicine men. A certain amount of license would have to be allowed, Col. THORNTON considers, to these partially trained assistants in prescribing for minor ailments. The dangers of such a course are obvious. A highly trained European nursing sister is liable to fall into errors of diagnosis through lack of medical knowledge, and it is doubtful if a faulty service is much better than no service. The Trained Nurses' Association, however, has expressed readiness to welcome a lower grade of women to be known as nursing aids, who shall undertake nursing assistance in rural areas. It is suggested that a training school should be opened at Durban, preferably under missionary auspices; Col. THORNTON estimates that if the American Board of Missions undertook the control of the scheme, the cost to the State would be not more than £10,000 yearly, provided that fees were paid by the patients wherever possible, and that bursaries were made available from the Native Development Fund. Health centres, he considers, should be established by preference in areas where natives undertake to build and keep in repair the necessary huts—the cost of equipment and staff falling on the Government. The advantages of this scheme lie in the comparatively small cost, and the speed with which nursing, medical, and midwifery aid could be brought to the native population in outlying districts.

ANNOTATIONS

OCCUPATIONAL THERAPY FOR PHYSICAL DISEASE.

MUCH has been heard lately about the importance of occupational therapy for mental disease, but less is written in this country about its value in all kinds of illness and convalescence. As applied in most institutions at present it is still in the somewhat amateur form that characterised occupational therapy in mental hospitals 20 years ago. Wise nurses give their patients little tasks to perform, and convalescent homes and like institutions provide unexacting games and sports. At the Toronto General Hospital occupational therapy has become a very important routine feature. The regular staff of the hospital includes assistants known as "aides" who have had a special two years' course in their subject, including instruction in anatomy, physiology, hygiene, psychology, and all kinds of handicrafts and remedial exercises. These aides work in close coöperation with the doctors, both in the wards and in the workshops. The hospital provides the materials and takes any profits from sales of finished goods. On the whole it is found better not to allow the patients any percentage of profits, as this makes them want to work at the more paying handicrafts instead of those peculiarly suited to their illness. For patients who do not need hospital care the work has been organised by the Ontario Society of Occupational Therapy, which obtained a charter in 1920. This society maintains a workshop where patients work under a doctor's prescription. Here the cardiac, arthritic, or nervous patient can be useful, self-respecting, and wholly or partly self-supporting, and patients with special disabilities can be set to do interesting work which will exercise just those particular muscles which need to be brought into play. For example, a marked improvement was obtained in an arthritic hand by making flowers out of beads and wire; a man with a badly injured wrist gradually restored it by working a shuttle on a weaving loom, and the value to the restless or depressed patient of regular constructive work needs no emphasis.

Three important results were obtained in London from an experiment of this kind at the Royal Free Hospital. The first was the mental benefit, which, of course, was anticipated. The second was the physical benefit; it was found that return to work was accelerated far more effectively by occupational therapy than by any kind of physiotherapeutic treatment. A man with a stiff elbow would be set to sawing and planing under a skilled carpenter; or a man with a dislocated shoulder would be set to sand-papering bed-table surfaces, raised each day a little higher until he was working above his head. The third value of the work, which was quite unexpected, was the remarkably effective test it provided for the malingerer or case with psychological retardation of recovery. The man who was genuinely keen to get back to work welcomed the occupational clinic with enthusiasm and reported his daily progress with pride. The man who did not want to return to work grumbled at the clinic and said it did him no good, but generally returned to his job quicker than he would otherwise have done, since he found his treatment "too much like work." Occupational therapy has therefore not only the obvious merit of leading a man gently across the bridge from complete idleness to full work, but might also prove a considerable economy to the country in sickness benefit. As a commercial proposition the work needs subsidising, for there is undoubtedly a difficulty in selling the goods made under these circumstances. Here a well-organised voluntary society, like the Toronto one, could be a great help, but apart from voluntary aid insurance companies might well find expenditure of this kind an economy.

There is at the present time some difficulty in obtaining assistants trained in occupational therapy. It is a branch of physiotherapeutic work which demands considerable ability and intelligence and should make a special appeal to educated women. There is an excellent opening for a physiotherapist who will start a centre for private patients. A room divided into 10 or 12 cubicles would serve a great number of patients coming by appointment for a certain number of hours a week, according to their doctor's prescription, to work at the loom, the carpenter's bench, the jigsaw-puzzle bench, the potter's wheel, or any of the various kinds of handicraft. It is however, of the utmost importance that the work should be directed by the medical man and that the profession generally should take a discriminating interest in the anatomical and physiological principle

nderlying the restoration of function, and in the articular variety of work or play best suited to bring bout the desired result.

PERFORATED PEPTIC ULCERS.

In a paper on Acute Free Perforation of Gastric nd Duodenal Ulcers Dr. C. Semb [1] gives figures uggesting that the behaviour of the perforated astric and duodenal ulcer has changed in some espects even in the course of a generation. His naterial consists of 166 cases treated at the Ullevaal Hospital, in Oslo, between 1912 and 1929. The lcers were duodenal in 36·5 per cent. and gastric n 63·5 per cent. Women were represented only by 31 cases, the proportion of men to women being, ccordingly, 4 to 1. Brunner's important statistical vork, published in 1903, showed a very different atio, only one-third of the patients being males. n 1911, Petrén showed that the sexes were about qually represented, and this finding was confirmed n 1915 by Shoemaker. Subsequent statistics have hown a steady fall in the relative incidence of erforating ulcers in women. The relative and bsolute increase in the number of cases in men has een attributed by the Swede, Bager, to the increased onsumption of cigarettes by young men, while German authors have connected it with an alteration n the diet since the war, notably an increased onsumption of meat. The age-curves of Semb's ases showed marked sex differences; whilst in women his condition was fairly evenly distributed in the arious age-groups, with only a slight preponderance etween the ages of 20 and 50, the men showed an ccumulation of cases between the ages of 20 and 29 nd, to a less extent, between 30 and 39. While he incidence of the acute perforating ulcer in women oes not seem to have changed in the period under eview, it has increased greatly in the case of men. he 26 deaths (total mortality of 15·7 per cent.) were istributed in such a way as to show how important re two factors—namely, the patient's age and the ength of the interval between perforation and operaion. The mortality rose from 5 per cent. between he ages of 20 and 30 to 14 per cent. between 30 and 0, reaching 40 per cent. in the case of patients over he age of 70. The position also of the perforating lcer seemed to influence the mortality, and the uxta-pyloric ulcer, with only 13 deaths among 127 ases (10·2 per cent.), showed the lowest mortality. hile the mortality was 25·8 per cent. for the women was only 12·7 per cent. for the men. As for the ngth of the interval between perforation and operaon, none of the 48 patients coming to hospital within x hours of perforation developed peritonitis, and he single death in this group was due to pneumonia. ine of the 112 patients treated within 12 hours of dmission died; and this mortality of 8 per cent. se to 18·4 per cent. in the case of the 38 patients perated on from 12 to 24 hours after perforation. he of the most encouraging features of this investigaon was the high proportion of complete recoveries bserved more than a year after the operation. was found that 75 per cent. had got rid completely their pre-perforation dyspepsia, and could tolerate kinds of food. Further, improvement was effected 19·4 per cent., the patients still being liable to ght dyspepsia or intestinal symptoms, but not being eatly troubled by them, and recovering when etetic precautions were taken for a time. So it was only in 5·6 per cent. that no cure could be claimed. The treatment in the overwhelming majority of cases consisted of suture with gastro-enterostomy and flushing out of the peritoneal cavity through a criss-cross incision in the right iliac fossa. With such good results from simple suture and gastro-enterostomy, Semb is not inclined to recommend the comparatively severe operation of resection except for such special indications as a bleeding ulcer or a suspicion of cancer.

MOVEMENTS OF THE EYES IN READING.

It was thought at one time that in reading the eyes move backwards and forwards smoothly and continuously and perception of the words takes place during the movement. But so long ago as 1878, as is pointed out by Miss M. D. Vernon,[1] Javal observed that this is not so. As the result of his observations and those of several more recent writers, it is now known that during reading the eyes move with a series of rapid jerks, with a pause after each movement during which the eyes are relatively at rest. On reaching the end of a line the eyes move smoothly to the left to the beginning of the next line. Only during the pauses which occur while the eyes move from left to right does perception take place, and the number of pauses varies greatly according to the age and reading experience (it is better to use this phrase than the word "education") of the subject of experiment, the practised reader being able to take in the sense of what he is reading with many fewer fixative pauses than the unpractised. In addition to the forward movements it is found that there are frequent movements of regression, especially with children and slow readers, who, as one would expect, take longer to perceive the meaning of a word or group of words than the older and more practised reader, but he too may have many regressions when reading an unfamiliar language or with his mind fixed on the style or spelling rather than on the context, as in proof-reading. The number of words covered by a fixation varies greatly, familiarly associated words and well-known phrases being read at a single fixation. The time occupied by the inter-fixation movements is very short compared with that occupied by the fixation pauses, probably not more than one-tenth, the rate being so great as to render it impossible for any perception to take place during movement. An interesting observation of L. Dor, of Lyon, quoted by Miss Vernon, shows that the causation of the movements is reflex, depending on stimulation of the peripheral part of the retina in the direction in which the eye is moving. The case was that of a woman with loss of the right half of the field in the right eye and such a degree of amblyopia in the left eye that with the left eye alone she was unable to read. When the left eye was occluded she was unable to read with the right, but when both eyes were open the stimulation of the retina of the left eye, although powerless to enable the left eye by itself to read, was yet sufficient to act as a stimulus to the right eye to move to the right and reading became possible.

In a further report lately published under the auspices of the Medical Research Council [2] Miss Vernon returns to the subject and describes a somewhat elaborate apparatus by means of which these movements can be studied by photographing a beam

[1] Brit. Jour. of Ophthal., March, 1928, p. 130.

[2] The Movements of the Eyes in Reading. H.M. Stationery Office. 1930. Pp. 45. 9*d*.

of light reflected from the cornea on to a continuously moving film. Experiments were carried out on nine subjects in the Psychological Laboratory at Cambridge. It was found that voluntary movements of fixation were performed accurately in only 20 per cent. of cases, on the average. There was a tendency, increasing with the angle of movement, for the eye to stop short of the correct point by an angular distance of the order of 1°, but occasionally it went too far. Return movements in reading from the end of one line to the beginning of the next were often either too short or too long. As might be expected, the rate of reading and the number of regressions for any individual subject of experiment varied greatly according as the matter read was such as to excite his personal interest or not. Fatigue in reading is chiefly due to the eye movements, whether they are of too small an angle necessitated by small print, each movement requiring to be more accurate than when the print is large or whether the backward movement from one line to the next is too long. It is said that lines of print not more than 8·5 cm. in length are the least fatiguing to the eyes.

THE LATE PROF. GLEY.

By the death of Marcel Eugène Emile Gley, in Paris last month, France has lost one of the most distinguished workers in physiology. Born 73 years ago in Lorraine, Gley was educated at Nancy, and later studied at Montpellier. He migrated to Paris and became assistant to Charles Richet in the department of physiology in the Faculty of Medicine. Later he was appointed to the Çhair of Biology in the Collège de France, an office which he held until his death. His work on the influence of peptones on the blood and liver, and above all his studies on the ductless glands, particularly the thyroid and parathyroid, gave Gley an international reputation. During the 'nineties over 40 publications on these glands are to be found in the *Comptes rendus de la Société de Biologie* and the *Archives de Physiologie*. Many workers from foreign lands came to work in his laboratory in the Collège de France. Last July the Institut de France awarded him the Osiris Prize in Physiology, and all arrangements had been made for its presentation.

"A.O."

Prof. Raikichi Arima, who directs the institute for experimental medicine known by his name in Osaka, Japan, remarks[1] that there are two ways of fighting tuberculosis. One is by dispensaries, sanatoriums, isolation of infectious cases, and so forth. The other is by the immunisation of the young against the disease. The first method, he says, has already proved to be not only too costly but unattainable, so that we are thrown back on the second method, with which in the West the names of Calmette and Guérin are associated. He recalls the remark of Prof. B. Lange at the Lübeck inquiry:—"I am convinced that in the tuberculosis campaign use must be made of every means, in itself harmless, from which there is any expectation of result." Medical practitioners are meeting every day human beings who are no longer susceptible to tuberculosis owing to having lived in a tuberculous milieu; it has been the aim of Prof. Arima and of his co-workers, Aoyama and Ohnawa, to imitate the example set by nature. The vaccine which they call A.O. is prepared from an antigen which immunises guinea-pigs and rabbits against an infection with highly virulent tubercle bacilli. It consists of bacterial protoplasm from many strains of the human type of tubercle bacillus, absolutely non-pathogenic because it is incapable of germination, easily measurable biologically, and easily absorbable, for the lipoid and fat content of the bacilli has been removed by the addition of a saponin derived from a species of sapindus, native to Japan. The vaccine has been used in prophylaxis, treatment and diagnosis. An injection of A.O. in a tuberculous patient reduces the leucocyte count after 30 minutes—the "Yoshida" reaction, which is held to be characteristic of active disease. After prolonged test on animals, A.O. was given to four volunteer tuberculous doctors, on whom its harmlessness was demonstrated. In 1927 the vaccine was recognised by the Japanese Government as a harmless product, and from 1927 to 1929 something over 150,000 persons were inoculated with it. Prof. Arima gives the result of 155 answers to a questionaire in which the percentage of cases cured or improved is never less than 53 (for severe pulmonary tubercle), and is as high as 96 for slight pulmonary affections, and 100 for tuberculosis of the skin. At an elementary school 413 children were inoculated, with the result that they lost their tendency to catch cold, to cough and sweat at night, and to glandular swelling; and an improvement was evident in appetite, nutrition, complexion, spirits, and general condition. In many cases, he says, it would be correct to speak of a change of life (*Lebensumschwung*). Confirmatory experience has appeared in the German medical press following an address by Prof. Arima at a recent Naturforscher und Aerztetag.

TREATMENT OF ACUTE RHEUMATIC FEVER.

The usual treatment of rheumatic fever is not supposed to have much, if any, effect on the more serious manifestations of the disease. Salicylates have strong antipyretic and anti-arthritic properties, but subcutaneous nodules may develop in patients under the full influence of these drugs, and their power to prevent carditis is by no means easily demonstrable. The search for other remedies, therefore, continues. Some time ago Small[1] claimed that serum prepared by inoculation of animals with *Streptococcus cardio-arthritidis* is able to arrest the progress of the disease, and Hitchcock, McEwen, and Swift[2] now report that they have carefully investigated these claims. In a series of cases exhibiting various rheumatic manifestations they used three types of antistreptococcal serum—viz., a commercial antiscarlatinal serum, a sample serum supplied by Small himself, and a serum prepared by the inoculation of a heifer with a green-producing streptococcus isolated from a subcutaneous rheumatic nodule. In none of these cases were unequivocal results obtained to show that the serum had produced any benefit; on the other hand, undesirable reactions following the serum were noted in 23 out of the 26 cases. Success, of even mild degree, could be claimed for the treatment in only 6 out of 20 cases which were properly controlled, and in none of these was the improvement more than what may follow simple rest in bed. Although the number of cases observed is small it seems fair to conclude that a general adoption of antistreptococcal serum in the therapy of rheumatic fever is by no means justified. A

ards salicylates, Leech[3] has recently published ervations on 67 children, the subjects of actual or ential rheumatic heart disease, to whom this ıedy, in the form of aspirin (grs. 20 daily) was ninistered over periods of six months. The ldren chosen were those showing no obvious evidence rheumatic activity. Not only did they show ver relapses and gain more weight than those in a ıtrol series, but also the signs of established cardiac ions diminished in more of the treated than the treated group.

THE NOBEL PRIZEMAN IN MEDICINE.

THE Nobel Prize for Medicine for 1930 has been arded to Dr. Karl Landsteiner, formerly of Vienna, l now of the Rockefeller Institute for Medical search in New York. His name is best known in ınexion with his work upon the blood groups, and may be truly said that he laid the foundations of present knowledge of this subject. Since the work Shattock in 1899 it had been recognised that some man sera had the power of agglutinating other man red cells, but this was regarded as a pathological enomenon. Working in 1900 and 1901 Landsteiner t only showed that agglutination of human red cells ıld be brought about by other human sera in the sence of any pathological conditions, but was able demonstrate that human beings could be ranged in tain groups on the basis of this reaction. Actually ndsteiner recognised what are now known as ups A (II.), B (III.), and O (IV.). In 1902 Decastello d Sturli, following up his work with his approval, monstrated the existence of Group A B (I). Land- iner showed that the constitution of the groups ıld be accounted for by the postulation of two glutinable substances or (as they are now called) glutinogens resident in the red cells and two homo- ous agglutinins resident in the sera. He believed t the agglutinins were reciprocal to the agglutı- gens, but this has since been proved not to be so. discovery was allowed to remain almost unnoticed years, although he specifically pointed out its ssible applications both in the practice of blood nsfusion and in the determination of paternity. e late war, with its great increase in the practice of od transfusion, brought his work into notice and ved the correctness of his opinions on this subject; only within the last few years has the truth and portance of his views on hereditary transmission the agglutinogens become generally recognised.

HE VOLUNTARY HOSPITALS OF LONDON.

NCE more the Statistical Review of the Work Finance of the London Hospitals, which has been issued by King Edward's Fund, is full of ouragement. Its financial and vital statistics, ch cover the year 1929, suggest that, so far as the ital is concerned, the voluntary system is meeting ever-growing strain upon it. All the figures e gone up—there are more beds, more patients, e expenditure, and more income. There has been aggregate deficit since 1926, and although the regate surplus last year was smaller than in 1927, was nearly three times as large as in 1928. y in one direction are the figures lower. The ıber of new out-patients has fallen by 4000, ch is probably accounted for by the physical tations of the out-patients' departments which, broadly speaking, will not hold any more. On the other hand, the attendances of this smaller number of patients of the 138 hospitals under review have increased by 84,000, which is clearly attributable to the larger course of treatment in such departments as light and massage, required by many patients. How much the pressure upon out-patients' depart- ments has grown is made plain by the increase of 1,154,000 attendances since 1925. Selective methods may reduce the actual growth of out-patient totals, but the constant introduction of new forms of treat- ment is certain to augment the attendances, and it is significant that while out-patients have increased by only 11 per cent. during the last half decade, their attendances have increased by 21 per cent. The experience of the great provincial hospitals is probably not very dissimilar.

Looking at the comparative figures of the last five years we find that 1810 beds have been added to the metropolitan hospitals during that period, to which 1929 contributed 380, the smallest increase since 1926, and a heavy falling-off from the year before. In view, however, of the cost of such exten- sions the addition of no more than a fraction over a bed every day instead of a bed and three-quarters, is not gravely discouraging. A "boom in beds" cannot be expected every year. That these 380 new beds only just met the demand is shown by the curious coincidence that the average number occupied increased by exactly that figure. In the report of an inquiry which King Edward's Fund recently made into the causes, incidence and extent of vacant beds, it is pointed out that any improvement in the percentage of beds occupied would, in effect, be as valuable as the building of additional bed accommoda- tion. The difficulty of keeping beds as fully occupied as possible, and at the same time of keeping a pro- portion available for emergencies, confronts most hospitals daily, but the report shows that the larger and the special institutions work up to approximately 90 per cent. of their capacity in those beds over which any effective control can be exercised. Those which are most frequently empty are "pay beds" chiefly because their availability is at present insufficiently known. With an increase of 10,900 in new in-patients last year, making a growth of 38,000 since 1925, the rate of increase in the beds occupied was higher than the rate of growth in the bed complement. Happily, as in-patients have increased, their average period of residence has fallen in the quinquennium by a whole day.

Another, and equally happy, circumstance in a different sphere is that, at £3,600,000, the maintenance income of the metropolitan hospitals in 1929 was a record, with an increase of £168,000 over the preceding year. Most of the improvement was, however, due to the uncertain element of legacies, though receipts from patients were more by £78,000. The growth of this source of revenue may reasonably be expected in the future to offset at the least the fall in donations. Over the whole period, however, there has been a large increase in voluntary gifts. To such gifts the hospitals still look for about one-half of their expendi- ture, which last year amounted to £3,550,000. Increased work is accoutable for some four-fifths of the growth in expenditure since 1925. In addition to the maintenance receipts, £220,000 was given for endowment and £865,000 for buildings and equipment; thus, the total receipts of the 135 hospitals last year reached the total, again a record, of £4,685,000. There could be no better proof of the solid progress that is being made with the allied problems of maintenance and expansion.

eech, C. B., Jour. Amer. Med. Assoc., Sept. 27th, p. 932.

A SUCCESSFUL ANTITUBERCULOSIS SCHEME.

SHEFFIELD has a tuberculosis scheme whose success (see p. 1039) is attributed to complete coöperation on the part of general practitioners in the town. In Sheffield there has never been any voluntary tuberculosis association, and the whole of the scheme has been built up under the ægis of the public health department, which has aimed from the beginning to enlist the practitioners' help. Effort has been made to obtain the services of tuberculosis officers with special clinical experience, whose opinion in a consultant capacity would be of real service to the family doctor. Since 1913 observation beds have been in use to facilitate diagnosis in doubtful cases, and for the same reason a modern X ray apparatus was installed at the dispensary in 1919. Practitioners have been encouraged to send doubtful cases to the dispensary for examination, and the tuberculosis officers are prepared to see patients at home in consultation with their own doctor. Care is always taken to give the doctor full information about his patient after examination and after discharge from hospital. The provision of institutional beds is so generous that when a practitioner has a patient likely to be benefited by hospital treatment there is no delay in his admission. At present the beds number over one per thousand of the population, without counting the King Edward VII. Hospital for surgical tuberculosis. In the early days patients were sent to outlying sanatoriums and a site for a municipal sanatorium was sought at a distance from Sheffield. Now, however, the principle has become established of having all the hospital beds within easy reach of the city. Most of them are close to a tram terminus or within an easy 'bus ride. When relatives are able to visit patients twice a week admission to hospital becomes more popular and there is less need for persuasion in the part of the practitioner. Special point has been made recently of providing beds for children with hilum tuberculosis, with the idea of so increasing their resistance as to prevent the onset of acute tuberculosis in later life; there is certainly little of the latter in Sheffield. All forms of tuberculosis are now being brought within the ken of the dispensary at an earlier stage. When King Edward VII. Hospital was first opened all the 130 beds were occupied by cases from Sheffield itself, many of them advanced cripples. At the present time only about 80 of these beds are needed for Sheffield and the cases come under treatment before crippling has become advanced. The other beds are available for the use of the surrounding districts. The scheme which we have sketched out is one to inspire confidence, and it is not exaggeration to say that the Sheffield scheme is based on the confidence of the local medical profession.

SILICOSIS IN THE POTTERY TRADE.

THE suggestion [1] that the problem of silicosis is becoming urgent in various industries carried on in this country is supported by a Home Office memorandum addressed to those concerned with the pottery industry. It states that since the Various Industries (Silicosis) Scheme came into force in February, 1929, no less than 113 cases, including 54 deaths in this industry, have been reported to the medical inspectors, and the adoption of further precautions for the prevention of silicosis are held to be required. Draft regulations embodying the proposals of the Departmental Committee on Workmen's Compensation for Silicosis in the Pottery Industry have now been drawn up. Since they are the outcome o careful inquiry, the Home Secretary hopes that the will be accepted without question. But it will b open to occupiers, workpeople, or others affected t lodge objections, and any objections of substanc will be considered before the regulations are finall made. The proposals of the committee include exter sions of the requirement as to exhaust ventilation; mor effective measures for cleaning potters' shops, includ ing the provision of impervious floors and shelve or other accommodation for moulds; and extensio of the requirements as to overalls and head covering cloakroom and messroom accommodation, and lava tories. In No. 10 of the draft regulations, restrictio of certain tasks, such as the cleansing of the floo of potters' shops and scouring shops, to an "adu male" suggests that evidence exists that wome and adolescents are more liable than grown men t contract silicosis. In the gold-mining industry n women are employed, so that experience there canno be the source of this regulation. Regular medica inspection of the exposed population, and especiall rigorous inspection of candidates for employmen is one of the measures most relied on in South Afric and we note with satisfaction that the Home Secr tary proposes to make provision for examinations b a medical board, set up under the Workmen's Com pensation (Silicosis and Asbestosis) Act of last sessio for workers in certain pottery processes. The annu report for 1929 [2] of the Miners' Phthisis Medical Burea on the Rand gives figures which are not easy t interpret for anyone not familiar with the metho of analysis to which they have been subjected; b evidently satisfaction is felt with the progress mad in preventing the incidence of the disease in "new Rand miners—that is, those men who have worke underground only since 1916. The fact that th disease takes a long time to develop, and that ever year the number of men classed as new Rand miner is increased by recruits to the service, makes th statistical presentation of the ascertained fac exceedingly complicated. But the chief lesson taugh by this amazing record of the organisation built u to cope with the ravages of silicosis is that the utmo effort must be made to prevent the scourge fro making further invasions into the industrial life our own country.

PRACTITIONERS AND MENTAL TREATMENT AC

MEDICAL practitioners who wish to be approved b the Board of Control for the purpose of makin recommendations in respect of voluntary patien below 16 years of age and temporary patients (und various sections of the Mental Treatment Act, 193 can obtain the necessary form of application b writing to the Board at Caxton House West, Tothi street, London, S.W., marking the envelope "M.T.D in the top left-hand corner. As the Act comes in operation on Jan. 1st, 1931, intending applicants a asked to write for this form immediately. The Boa states that it cannot entertain applications fro medical practitioners of less than five years' standin on the Medical Register.

THE next session of the General Medical Coun will commence at 2 P.M. on Tuesday, Nov. 25t when the President, Sir Donald MacAlister, will tak the chair and give an address. The Council w continue to sit from day to day until the terminatio of their business.

MODERN TECHNIQUE IN TREATMENT

Series of Special Articles, contributed by invitation.

CCCX.—NEONATAL ASPHYXIA.

PART I.

THE treatment of the asphyxiated new-born baby as undergone radical changes in recent years. one are the days of barbaric violence when deeply nocked infants with white asphyxia were waved ver the operator's shoulder as in the "Schultze" ethod, or, as suggested by Byrd, bent double nd then extended, thus frequently being killed y increased shock and rupture of the liver. I am tisfied that the baby with white asphyxia is never ved by artificial respiration in the ordinary sense the words. An infant with white asphyxia who is ceiving artificial respiration may breathe and recover. ut this, though probably claimed as a triumph for the ethods of violence, should really be regarded as somewhat remarkable recovery despite the added auma to which the child had been subjected. here is some danger nowadays of going to the her extreme by attempting to replace the old olent methods by others too complicated, or eding too much in the way of elaborate and pensive apparatus, to be of any use to the actising obstetrician. For example, an apparatus ed in an American institution provides an airtight binet wherein the asphyxiated child is placed th only its head outside. The air in the cabinet then partially exhausted by an electric pump out 15 times a minute and thus atmospheric air sucked through the ordinary air passages into e child's lungs. Thence it is expelled when the r-pressure in the cabinet is allowed to return to rmal. There appears to be no doubt about the icacy of this apparatus in making asphyxiated fants breath. The fault appears to be, on the ntrary, that children with extensive intracranial emorrhages are caused to breathe though they are omed to subsequent death as the result of the head jury. But apart from this disadvantage the paratus is quite impossible to provide except in ge maternity institutions. A somewhat less mplicated machine has been described and used in is country by Prof. Louise McIlroy; the child is pt warm in a box with an atmosphere of 6 per cent. rbon dioxide in oxygen. But the advantages be gained from such an apparatus would seem to hopelessly outweighed by the practical difficulties. The ordinary accoucheur needs a straightforward hnique requiring only simple apparatus, and e which he can employ under any circumstances. is necessary to distinguish between the methods table to the "blue baby" and those required for es of asphyxia pallida in which the child is white l limp.

Blue Asphyxia.

First with regard to "blue babies"—those suffering m "asphyxia livida." It may at once be stated t these infants are comparatively difficult to l and artificial respiration need not be regarded necessarily a murderous procedure. But preferably atment such as that subsequently to be outlined uld be used. And for such treatment it will be n that some form of mucus extractor is essential. must be emphasised that clearing the upper air sages is the first essential in the treatment of cases of asphyxia in new-born babies, and further, t a suitable extractor forms an integral part of the obstetric equipment of every person attending a confinement. The type to be employed must also possess, not a metal end, as is so frequently illustrated, to go down the child's throat, but a soft rubber one which will cause no injury to the delicate tissues of the infant.

The procedure, then, to be adopted in the case of a baby with blue asphyxia is as follows: wipe all mucus, &c., away from the nostrils with a soft mop of gauze or cotton-wool. Wipe the mucus out of the child's mouth with a small piece of soft gauze twisted around a little finger (gauze is better than wool for this purpose since it is less likely to slip off the finger). Do not be in a hurry to separate the child from the mother—it is quite unnecessary to clamp and divide the cord at this stage. Pass the soft nozzle of the mucus extractor, guided by a little finger, well to the back of the infant's pharynx and suck out all moisture. Repeat the process, directing the nozzle successively to all parts of the mouth, nostrils, and pharynx where mucus has collected until the whole of the upper air passages has been cleared. In all probability the child will now breathe; if not, support the back of the child's chest on the palm of one hand and allow the head to drop slightly back so as to open up a good airway. If necessary, hold the tongue forward either by a finger and thumb, holding a piece of gauze to give a grip, or by a sharp single pronged clip forceps such as a "towel-clip," or by means of a suture passed through the tongue with a fine needle; rub some brandy gently with a little finger on the gums and on the inside of the lips and cheeks; compress the thorax gently with a hand and then allow the recoil to inspire air into the lungs. Repeat this manœuvre slowly—certainly not more often than six times a minute—and gently.

Even smacking the blue baby or stimulating it by splashing a little cold water on its skin will probably do no harm, and usually such infants will respond fairly quickly to the treatment described above and will start breathing normally. Then they can be separated from the mother in the usual manner. But should normal respiration not easily be established and particularly should the infant gradually change from the state of being blue while its limbs exhibit good muscular tone, into the condition of limpness associated with pallor, then it is essential that the treatment appropriate for white asphyxia should immediately be adopted. It is because of this danger of change from blue to white asphyxia that any violent movements such as those of artificial respiration are to be deprecated even in the treatment of the milder condition, otherwise in consequence of such violence this condition may become changed into the more serious one.

Before leaving the subject of blue asphyxia mention should be made of a suggested line of treatment by allowing some fœtal blood to escape by dividing the umbilical cord. It is claimed that by thus relieving the circulation the embarrassed fœtal heart is enabled better to function and that the respiratory centre, in receipt of a more efficient blood-supply, is thus enabled to initiate normal respiration. This, of course, would not apply to cases of "asphyxia pallida"; and even in blue babies the loss of blood to the circulation does not seem to me to be advisable. I have consequently had no experience of this line of treatment.

LESLIE WILLIAMS, M.D., M.S. Lond., F.R.C.S. Eng.,
Surgeon to Out-patients, Queen Charlotte's Hospital.

SPECIAL ARTICLES

MEDICINE AND THE LAW.

Post-mortem Examinations.

IN dealing with matters which fall under this section of medical practice, the propriety of a post-mortem examination, and, generally, of the circumstances when autopsies are indicated, frequently have to be discussed. The statutory provisions governing post-mortem examinations are to be found in the Coroners Act, 1887 (50 and 51 Vict., c. 71), Section 21, and the Coroners (Amendment) Act, 1926 (16 and 17 Geo. V., c. 59), Sections 21–4. The 1887 Act was in part a consolidating Act, and restated existing law.

But an important change was made in 1926 which enabled a coroner to have a post-mortem examination without necessarily proceeding to hold a formal inquest, and questions on the subject are often put to us. The statistics showing the extent to which this concession has been employed are not yet complete. The 1926 Act was in operation for eight months only of the year 1927, since it did not take effect till May 1st, 1927. The annual criminal statistics down to 1927 showed the numbers of deaths reported to coroners, the number of lunatics and persons in institutions where a post-mortem examination is always made, the number of deaths investigated by a coroner where no inquest was held, the number of inquests and the number of post-mortem examinations ordered by the coroner. Since the operation of the 1926 Act the statistics show the number of post-mortem examinations "directed or requested" by the coroner, and this total is subdivided into "inquest cases" and "non-inquest cases." For the year 1927, when 60,511 deaths were reported to coroners, the eight months' figures of post-mortem examinations directed or requested by coroners were 12,904 in inquest cases and 3616 in non-inquest cases. For the year 1928, when the total of deaths thus reported was 62,501, the post-mortem examination figures were 11,127 in inquest cases and 6791 in non-inquest cases. The non-inquest figure, it will be noticed, was more than doubled at the end of the second year of the full working of the change introduced by the 1926 Act. The figures for 1929 will not be published till the official volume of Criminal Statistics for England and Wales of that year appears; it is not to be expected before next year. In the meantime the Home Office has stated that in 1927 there were 24 boroughs and 5 counties in which no use had been made of the new power; in 1928 there were 21 boroughs and 7 counties. The saving of time, trouble, and expense by having a post-mortem examination without necessarily having an inquest is so conspicuous that the power is likely to be constantly more freely used. It may be added that the coroner is now remunerated by the year and not by the inquest, and that adequate fees are ensured (by Section 23 of the 1926 Act) for medical practitioners who hold post-mortem examinations and give evidence at inquests.

Birth Registration Offence: Story of Suppositious Child.

A woman was convicted at Sunderland recently on a charge of perjury in respect of registering the birth of a child. The case put forward by the prosecution was remarkable. The accused, a married woman 37 years of age, was said to have adopted an illegitimate child and to have passed it off as the offspring of herself and her husband. The child was produced in court and was identified by a widow whom, in the light of the magistrates' decision, one must regard as the actual mother. The widow stated that the child was born to her on Jan. 15th, and that on March 25th she advertised for someone to adopt it. According to the prosecution, the accused bought long clothes for the baby, and had it brought to her own house by night on April 18th; the real mother came to the house every morning for a fortnight ostensibly to attend to the accused and the child she was addressed as "nurse." A medical practitioner happened to be attending the accused for pleurisy she took advantage (it was said) of this circumstance to represent that he was attending her in her confinement. A note bearing his name was sent to the medical officer's office to notify the birth as having occurred on April 18th—the date when, according to the prosecution, the three-months'-old child was conveyed to the house. The doctor repudiated the note. His evidence was that, during his visits to the accused, she told him she was pregnant, but declined to let him examine her. On April 19th he was sent for and found her in bed with a child all wrapped up she said she was all right, and that nurses were attending her. Accepting her story, which there was apparently no reason to suspect, he subsequently signed a certificate enabling her to obtain maternity benefit. The chief inspector of police said he obtained from the accused the name of the woman who was attending her, but he was unable to trace any such person. The accused had the child christened in her own name, and she registered the birth stating it to be the child of herself and her husband. On the other side the defendant flatly denied the story of the adoption. Her husband and neighbours gave evidence in support of her statements that the child was born to her on April 18th. Having found her guilty, the magistrates fined her £10. This was the maximum on summary conviction until in 1925 the penalty was increased to £50. Had the charge been sent to the assizes for disposal—and such disputed issues of fact might well be thought more appropriate for decision by a jury—the maximum sentence would have been seven years' penal servitude.

In 1926, when the law of death certification and registration was amended, critics complained that there was still every opportunity left for premature burial and every facility for the concealment of crime. Irregularities in connexion with the registration of births are perhaps not so serious as those with respect to deaths, but the Sunderland case suggests that here, too, the law may require re-examination. The medical practitioner is not primarily responsible either for notifying or for registering a birth, but existing statutes put upon him an indirect or secondary responsibility. He would be closely concerned in any proposed change.

Medical Privilege Again.

The difficulties of the medical practitioner who is asked in the witness-box to disclose matters of professional confidence were illustrated afresh lately in the King's Bench Division. A practitioner from University College Hospital (subpœnaed to give evidence) asked for the protection of the judge on the

ound that his testimony concerned matters privileged between doctor and patient. Mr. Justice cnaghten replied that there was no such privilege own to the law and that the witness was bound answer any relevant question of which he had owledge. Counsel interjected a remark that the tness was putting forward the view of the hospital thorities, whereupon the judge professed astonish-nt that the hospital authorities should be so norant of their duty. Hospitals, we may guess, are t only concerned with professional etiquette but o dislike the disturbance of medical and surgical vices which occurs if their staffs are summoned to nd what may be many hours in the law courts. gally they are powerless to protest. If a hospital uses to send a witness, the court can direct the ole personnel of the hospital to attend. This tential threat was held over a hotel manager lately en he showed reluctance to allow his domestic ff to appear as witnesses in divorce cases; it was plained to him that the whole staff of the hotel ght be ordered to attend if he made any difficulty.

On the question of medical privilege and the tection of a patient's confidence, the fact that a ge insists on having the evidence should not deter witness from making his protest. There is a lespread feeling that medical privilege should eive statutory recognition in the interests of ients in general. This change will not be brought ut unless public opinion is stirred. It is necessary keep the matter before the public; every practi-ner who protests against being asked to disclose patient's confidences does good service for this pose.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

CIENTIFIC COMMITTEE FOR MEDICAL INVESTIGATION.

A SCIENTIFIC Advisory Committee on Medical ministration and Investigation has been appointed he Secretary of State for Scotland. The reference he Committee is: "To assist the Department of lth for Scotland in applying the results of scientific arch to the details of public health administration in promoting such medical investigations as come in the sphere of the Department or of the local horities in Scotland." The members of the mittee are as follows:—

Alex. Bowman, D.Sc., Scientific Superintendent of Marine Laboratory of the Fishery Board for Scotland.
C. H. Browning, F.R.S., Professor of Bacteriology in University of Glasgow.
E. P. Cathcart, F.R.S., Professor of Physiology in ersity of Glasgow.
F. A. E. Crew, Professor of Animal Genetics in the ersity of Edinburgh, and Director of Animal Breeding arch Department.
Walter Fletcher, M.D., F.R.S., Secretary of the cal Research Council.
Robert Greig, Secretary of the Department of Agricul-for Scotland.
John Jeffrey, Secretary of the Department of Health cotland.
J. Parlane Kinloch, Chief Medical Officer of the rtment of Health for Scotland.
A. S. M. Macgregor, Medical Officer of Health for ow.
T. J. Mackie, Professor of Bacteriology in the University linburgh.
J. J. R. Macleod, F.R.S., Professor of Physiology in niversity of Aberdeen.
Robert Muir, F.R.S., Professor of Pathology in the rsity of Glasgow.
J. B. Orr, Director of the Rowett Institute for Research imal Nutrition, Aberdeen.
W. J. Tulloch, Professor of Bacteriology in the rsity of St. Andrews.

Dr. Parlane Kinloch is the chairman of the Committee, and Mr. George Wallace, of the Department of Health for Scotland, is the secretary.

The appointment of the Committee follows on the conference of research organisations which was held in Edinburgh in November of last year. A more intensive use of Scottish research material and the correlating of work in the biological sciences, having a bearing on medical as well as on agricultural, fishery, or other fields, was urged at the conference. It was also urged that a Scientific Advisory Committee would secure for community health purposes the application of the most recent results of medical research.

THE BRIDGE OF ALLAN SPA.

By invitation of the provost and town council of Bridge of Allan and Mr. Holdsworth Lunn, chairman and managing director of the Spa Hotel, a large and distinguished company attended the reopening of this once famous Scottish spa on Oct. 30th. The Scottish Department of Health was represented by Sir Leslie Mackenzie and Dr. Alex. Shearer. In declaring the spa open Sir Humphry Rolleston recalled the establishment of the well-house at Airthrey in 1821 by Sir Robert Abercromby, after a favourable report on the medicinal value of the waters by Prof. Thomas Thomson, of Glasgow. In the middle of last century 30,000–40,000 people visited Bridge of Allan every year to take the waters, but no effort was made to modernise the equipment of the spa. Now, he added, the place had a triple qualification for assured success: great natural advantages in climate, scenery, and associations; exceptional chemical composition of its water; and a fine up-to-date equipment.

Dr. Fortescue Fox said he had not found more than 10 or 12 waters in the world precisely comparable with those of Bridge of Allan. Their total saline strength was about 10 parts per 1000—i.e., nearly isotonic with the body fluids, and thus suitable for drinking, while their calcium content was exceptionally high (ca. 4·5 per mille), and in a highly assimilable form. Llandrindod and Llangammarch in Wales were similar, but were not so rich in calcium (about 1 per mille). Woodhall Spa came nearer (3·5), but was too strong in table salt to be drunk without dilution. Homburg and Kreuznach, in Germany, had about half the amount of calcium. The nearest comparison was with the great springs of Saratoga (New York), used for functional disorders of the stomach, gastric and intestinal catarrh, and constipation; and the United States of America possessed three other waters of this type. Owing to the chloride, calcium and other elements contained in them, the Bridge of Allan waters covered a rather unusually wide range of usefulness in the prevention and cure of illness. The four chief classes which would derive benefit from them were: (1) delicate children, (2) people affected with respiratory and (3) with digestive troubles, and (4) many people suffering from certain forms of rheumatism and other exudative diseases. Mr. Judd Lewis, D.Sc., Chairman of the International Standard Measurements Committee, confirmed the remarkable content of calcium, iodine, and bromine in the spring water.

After the opening ceremony opportunity was given for visitors to examine the establishment, which has been entirely reconstructed. Although small, it forms a complete unit of treatment, by baths, douches, inhalations, radiation, and electricity, and there is a sun lounge entirely fitted with Vita-glass. The spa will be open throughout the year, and as its situation gives it much sunshine and complete freedom from

cold winds, it should be a welcome refuge for visitors in the period from February to April.

A NURSING HOME FOR OFFICERS.

The Officers' Association (Scottish Branch) has established a nursing home in Edinburgh for ex-officers. In opening the institution, the Duchess of Atholl commented on the difficulty that such men had to fit themselves into other forms of work or to find alternative work of any kind. Reductions in the Services were inevitable after a great war, but people did not always remember what acute personal problems might be the result of these reductions. The home is for officers and ex-officers of the Royal Navy, the Army (including the Territorial Army), or the Royal Air Force, who must either be or become members of the Officers' Association. No charge is made for maintenance or nursing, but the officers are responsible for the payment of their physicians, surgeons, and for treatment, subject to any special arrangement between individual officers and the nursing home committee. The patients may select any physician or surgeon to attend them.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

PUBLIC HEALTH NEEDS IN THE FREE STATE.

THE Department of Local Government and Public Health is making persistent endeavours to persuade the more dilatory county councils to fulfil their statutory duty of appointing county medical officers of health. The County Dublin is one which has so far neglected its duty in this respect, and, in a recent letter to the Dublin County Council, the Department points out that there are special reasons why the health of the metropolitan county should receive attention. It contains within itself the largest borough in the country—namely, Dun Laoghaire—while its contiguity to the capital city exposes it to special dangers, and imposes on it special responsibilities. Moreover, though much of County Dublin is rural, even the rural areas have a bad record as regards health. Both in general mortality from all causes and in infant mortality the rural areas are worse than the urban areas in the same county as previously constituted. The infant mortality of the rural areas of the county exceeds by over 73 per cent. the average incidence in the rural areas generally of the whole of the Irish Free State.

The Department forwarded with its letter to the Dublin County Council a very informative memorandum dealing with the general need for public health reform in Ireland. It is stated that public health organisation has been hitherto definitely behind modern requirements, owing largely to the fact that the local health officers were primarily engaged in treating disease. In recent years more searching criticism, from external as well as internal sources, had made clear the need for reform. As a specific instance of such criticism is quoted the fact that as a result of a recent outbreak of typhus fever in the Letterkenny district, the United States public health authorities had placed an embargo on immigration from that area. It is stated, too, that the more effective control, from the point of view of health, of the production of food in England and Denmark had placed Ireland at a commercial disadvantage. Unless adequate assurance can be given that Irish meat supplies and dairy produce are above suspicion there is a danger of markets being closed to Iris exports. The Department points out that infectio and disease have little respect for arbitrary admini trative boundaries, and it is beyond dispute that th best results in the prevention of human sufferin and death are achieved in large areas of local contro

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

A HYDATID REGISTRY.

THE College of Surgeons of Australasia have decide to establish a Hydatid Registry, an idea no doul suggested by the registry of bone sarcoma founde some years ago by the American College of Surgeon It is intended to investigate every possible instan of human infection in Australia and New Zealan and correlate the records obtained. The regist will be kept in New Zealand by Dr. R. A. H. Fulto of 2, Pitt-street, Dunedin, who has been appointe Registrar, and who will each year issue a summa of the cases, with the conclusions to be draw from their analysis. Sir Louis Barnett, Dr. H. T. Ackland, and Prof. F. Gordon Bell will be the Ne Zealand committee in charge of the investigatio Special record forms have been circulated to t medical superintendents of all hospitals in Austral and New Zealand, and are available for medic practitioners, on request.

Although hydatid disease is more common Australia than in any other English-speaki community, it is, perhaps, surprising that it is n in fact, more common than it is. Clunies Ros investigating hydatid infestation in New Sou Wales, found that from 15 to 16 per cent. of do examined in country districts harboured the *Tæn echinococcus*, with an average infestation of 18 p cent. These figures are probably well below the mar He found that the infestation of dogs in the vicini of slaughter-houses and at sheep stations w particularly high. This has been confirmed by t Melbourne University Veterinary School, who fou that 100 per cent. of the dogs around the municip abattoirs were infested. This infestation is attribut to the habit of throwing to the dogs all the viscera the slaughtered sheep. Prof. H. R. Dew, in his boo has shown that the distribution of hydatid disea in Australia follows the sheep distribution. Thou in New Zealand the proportion of sheep per head population is higher than in Australia, the proporti being 15·3 and 13·0 respectively per head of popul tion, hydatid disease is not so common in Ne Zealand as in certain parts of Australia. In Australi the disease is most common in Victoria, whilst i rarity in Queensland is remarkable. It is obvio that the main attack must be directed against t dogs, particularly those around slaughter-houses a on sheep stations. Clunies Ross, amongst oth recommendations, has suggested the administrati of arecolin hydrobromide to all such dogs once eve three months. Fondling or handling dogs, a allowing them to lick the hands, is regarded as dangerous practice, particularly for children.

There is no doubt that the establishment of t registry will be the means of increasing our knowled of the disease, and perhaps of directing great attention to methods of eradication.

[2] Hydatid Disease, Sydney, 1928.

LONDON MEDICAL EXHIBITION.

(*Concluded from p. 989.*)

WE conclude this week an account of the exhibition, ontinuing, first, the notes upon

Drugs and Pharmaceutical Preparations.

A stand of interest to many was that of INGRAM ND ROYLE, LTD. (45, Belvedere-road, S.E.), where a rge variety of the natural mineral waters in use for fections of the kidneys and bladder and for gout id rheumatism was displayed. The indications for ie employment of natural Vichy salts, Contrexéville, vian, Carlsbad, and Hunyadi-János waters are well nown, while the waters from other springs, such as ose of Ems, Kissingen, Plombières and Vittel, have any adherents, and the prescribing of Geisshubler ater is becoming popular in practice. That Abanah id Pharpar may, however, be as efficacious as the ordan was the reason for stands at which the claims Harrogate and Bath in different directions as lneological centres were justified. At Harrogate ie diversity of waters, each possessing distinctive haracteristics, was set out by a representative of the pa Directorate, while the chief analyst was also in tendance at the stand. The bathing establishments re are under the supervision of the Harrogate edical Society. The same coöperation between the thing establishments and the medical profession sts at Bath, and the exhibit sent by the corporation owed the famous Roman spa to be quite modern in scientific developments.—At the stand of SOAPLESS AM, LTD. (17, Dover-street, W.), a demonstration as given of the Sandor foam baths as an adjuvant to e treatment of rheumatism, nervous debility, and æmia, much printed evidence of the efficacy of these ths in the different conditions being advanced by ntinental physicians over the last four years.—E BRITISH ORGANOTHERAPY CO., LTD. (22, Golden-uare, W.), showed a wide range of glandular products d in particular asked medical visitors to give a trial Saccharomycin (B.O.C.), a fluid living yeast valuable furunculosis and acne; to Evatmine, a compound pituitary extract, adrenalin, and salt, of value in e treatment of spasmodic respiratory affections as uched for by a group of medical men; and to Opojex, ramuscular injections of which are of assistance ring labour.—At the stand of THE MOND STAFFORD-IRE REFINING CO., LTD. (Abbey House, Westminster, W.), particulars were being given of the germicidal perties of Monsol, attention being directed to its lity in obstetric practice.—THE BRITISH CATADYN ., LTD. (Southampton-row, W.C.), have given this me to a preparation of silver fixed in a non-colloidal m on suitable carriers, exposing a large surface. e testimonials to sterilising action come from official rces and establish a claim for a trial, as was said our columns recently (THE LANCET, August 2nd, 280) in referring to the severe and critical tests ich have been applied to the catadyn method of rilising water.

At their respective stands, such well-known firms BOVRIL, LTD. (148 to 166, Old-street, E.C.), C. ENO, LTD. (Fruit Salt Works, Pomeroy-street, .), CADBURY BROS., LTD. (Bournville), and HOVIS . (London, Macclesfield, Manchester, and Bristol), vided general information, documented where essary by medical evidence, as to their wares.—ERGEN FOODS CO., LTD. (Willesden, N.W.), showed s based upon their special breads, biscuits, and lth foods, as indicated in the dietetic treatment liabetes and obesity.—VIROL LTD. (Hanger-lane, ing, W.), exhibited a food designed to meet the ticular requirements of the age of growth, and the is able to call in support of their claims investi-on in the laboratories at Cambridge.—BRISTOL-ERS CO. (112, Cheapside, E.C.) showed the effer-ent saline laxative Sal Hepatica, and also a tooth te, Ipana, which contains an antiseptic of the hthalene series which has proved effective in dental disorders and elsewhere.—THERMOGENE CO., LTD. (Haywards Heath, Sussex), showed on their stand sample boxes of this medicated wadding for employment in situations where the troublesome application of poultices and fermentations used to be the routine. —Kaylene, which is a derivative of kaolin, was shown in several forms by KAYLENE, LTD. (7, Mandeville-place, W.), the claims for the preparation being that, in a colloidal form, it presents a combination of properties essential to an active adsorbent of intestinal toxins.—GENATOSAN, LTD. (Loughborough, Leicester), displayed their various productions, such as Sanatogen, Genasprin, Formamint, detoxicated and ordinary vaccines, and calf vaccine lymph.—TRUFOOD, LTD. (The Creameries, Wrenbury, Cheshire), asked attention for their milk products, including a Humanised Trufood, closely approximating to breast milk; this is a full-cream preparation for which the claim is made that it possesses the attributes of Grade A milk.

Surgical Instruments and Appliances.

JOHN WEISS AND SONS, LTD. (287, Oxford-street, W.). This firm, which contracts for H.M. and the Indian and Egyptian Governments, and supply British, foreign, and Colonial hospitals, displayed a large selection of instruments. These comprised many recent designs, and useful additions to an extensive range of ophthalmic instruments; an operation lamp, the patent of the firm, was noticed closely on account of its separate water-filter attachment for projecting microscopic slides, whose employment in teaching is being steadily found more valuable.—ARNOLD AND SONS (Savory and Moore (1928), Ltd.), in association with JOHN BELL AND CROYDEN (50–52, Wigmore-street, W.), displayed a large selection of hospital furniture and of instruments made of stainless steel.—The collection exhibited by DOWN BROS (21–23, St. Thomas's-street, S.E.), on three stands included many instruments recently made at the suggestion of well-known surgeons. In view of the discussion to be held in a few days at the Otological Section of the Royal Society of Medicine on precancerous conditions of the larynx, Howarth's improved model of Chevalier Jackon's Bronchoscopy and Œsophagoscopy instruments came in for close notice.—THE HOLBORN SURGICAL INSTRUMENT CO., LTD. (26, Thavies Inn, Holborn Circus, W.C.), asked visitors to ascertain for themselves the advantages of the Holborn twin pump operation table, as the mechanism for placing the subject in the best position for operation is ingenious and easy to work with the foot, while the head and leg straps are conveniently adjustable. The firm also showed a large selection of electric apparatus.

RADIUM ELECTRIC, LTD. (24, Grosvenor-gardens, S.W.), exhibited the Q-Ray Electro-Radium Compress, a recent development in the field of mild radium therapy. This is a combination of dry heat and radium. The radio-active strength, as certified and guaranteed by the Berlin and Vienna Radium Institutes, is 0·013 mg. The compresses can be obtained on loan for testing purposes by medical men without obligation.—T. J. SMITH AND NEPHEW (42, Tavistock-square, W.C.). Through the regular houses for the distribution of surgical material the elastroplastic bandages of this firm can always be obtained. Elastroplast is the trade name for a resilient and adhesive dressing which is supplied either ventilated or in a form which permits bathing without removal. The bandages can also be obtained impregnated with drugs, the lesion indicating the particular kind of medicated dressing to be employed.—BRUCE GREEN AND CO., LTD. (14, 16, 18, Bloomsbury-street, W.C.), make a speciality of optical appliances and showed all types of instruments for ophthalmic work—e.g., optical trial cases, facial measuring sets, ophthalmoscopes, and retinoscopes.—R. H. DENT (309, Oxford-street, W.) displayed the "Ardente" apparatus in different types.—PHILIPS LAMPS, LTD. (145, Charing Cross-road, W.C.), on two stands, showed the Metalix-portable X ray outfit, and throughout the exhibition its simplicity and compactness were demonstrated to visitors. The necessary current can be obtained

from the ordinary light mains.—THERMEGA, LTD. (53, Victoria-street, Westminster, S.W.), showed the Thermega electric radiant blanket, which has been found useful in supplying a dry warmth in a convenient manner to patients suffering from many forms of pain or disability. The cost of the current used per hour, at 6d. a unit, is said to be only ¼d., while the blankets are designed to reach a temperature of approximately 105° F. within the hour. A patent thermostat controls the temperature and makes overheating impossible, and the blankets are made to suit any voltage from 50 to 250 with adjustment.

CAMERON SURGICAL SPECIALITIES, LTD. (57C, New Cavendish-street, W.), exhibited complete medical and dental sets for diagnosis by transillumination of the nasal sinuses, the alveolar process, and the eye. An important exhibit was the Cauterodyne, a radio-frequency cautery indicated for use in carcinomatous conditions, where this method of operation is becoming increasingly popular, following on the experience of Harvey Cushing, Wyeth, and others.—THE DOMEN BELTS CO., LTD. (26, Sloane-street, S.W.), showed the latest models of their abdominal corsets and belts applicable to various conditions, hernial, post-operative, and traumatic. The firm also asked attention for a new bandage, the Poro-lastic, as particularly useful in cases of varicose veins and the conditions remaining after phlebitis or sprains.

Publications.

BAILLIÈRE, TINDALL AND COX (7–8, Henriett Street, W.C.) exhibited a representative collection their publications which included the 13th edition Rose and Carless's "Manual of Surgery," the 10 edition of Cabot's "Physical Diagnosis" and t 3rd edition of Eyre's "Bacteriological Technique Nicole's "Psychopathology" had a prominent pla on this stand.—WILLIAM HEINEMANN (Medical Book LTD. (99, Gt. Russell-street, W.C.), exhibited Jacob "Atlas of Dermochromes," with English text Dr. H. MacCormac, Souttar's "Radium and Surgical Applications," and other popular wor of medical interest.—JOHN WRIGHT AND SONS, LT (Bristol), the publishers of the "Medical Annual" a the *British Journal of Surgery*, called particul attention to a French "Index of Differential Dia nosis" and to Tidy's "Synopsis of Medicine."—H. LEWIS AND CO., LTD. (Gower-street and Gower-pla W.C.), the founders and organisers of the well-kno medical library, exhibited, together with an assortme of medical publications, the Lewis's Card Syst of book-keeping and case-taking, a system specia designed for the convenience of the practitioner.

The Exhibition was a success, a large number doctors attending, to learn the value and applicati of material aids to practice, placed at their dispo by applied chemistry and physics.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of three cities:—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Glasgow .. (1,074,881)	21·2	16·5	1·26	1·37	4·2	2·2	107/37	64	8·3
Sheffield .. (518,000)	15·4	13·2	0·95	1·40	3·1	1·8	88/39	44	6·6
Leeds .. .. (478,500)	15·5	16·5	1·30	1·43	4·2	2·6	97/42	74	4·4

Stillbirths per 100 live births: Glasgow, 4·8; Sheffield, 4·8; Leeds, 5·0.

Glasgow.

Dr. A. S. M. Macgregor looks forward with great interest to the census of 1931, as the accuracy of the 1921 census was open to question. The Registrar-General's estimate of Glasgow's population is 85,839 less than the local estimate and on the larger local estimate the birth-rate becomes 19·6, the death-rate 15·3, and the other rates per 1000 of the population are lowered in proportion.

Glasgow was one of the first cities to feel the influenza epidemic. In the closing days of December, 1928, influenza was rife among the crews and passengers of ships arriving from America, and the Glasgow epidemic began in the week ending Jan. 5th, 1929. Three weeks later the maximum mortality was reached of 53·4, and in another three weeks the epidemic was over. Concomitantly there was fog and cold weather. The deaths from pneumonia (2447) were higher than in any previous year. Hospital accommodation was strained to the utmost. At one time over 600 beds were occupied by pneumonia cases, of which about 60 per cent. were admitted. The prevalent type was a severe broncho-pneumonia. The voluntary hospitals and poor-law authorities a the district nursing association coöperated in ev possible way. The death-rates at the extremes f life were unusually heavy. The rates for the rema ing quarters of the year were noticeably low, a the measles epidemic, which occurred in the th quarter, was the mildest ever experienced, with comparative absence of pneumonia. It is poin out that the behaviour of pneumonia from year year is responsible more than any other single fac for the fluctuations in the general death-rate. Stud of the incidence of pneumonia reveal no tende to diminution and there are no clearly defin principles of prevention. Ready admission to hospi is the only feasible course, and better arrangement the existing hospital facilities is one of the import problems of the future. Detailed inquiry as to incidence and spread of respiratory diseases in selec areas is in progress, and also laboratory investigat of the types of organism concerned.

The rapid decline in pulmonary tuberculosis spite of the small and often overcrowded hou Dr. Macgregor finds it difficult to account f. Administration is being assisted by some unkno agency. There are two striking features in decline. The first is that no impression is being m on the incidence and severity of acute phth affecting young adults of either sex. The second a remarkable fall in phthisis at later years, m marked among women. These features have b clearly brought out by Dr. J. A. Wilson for an east area of the city with a population of 200,000 perso Non-pulmonary tuberculosis has declined even m rapidly. Since the first decade of the cent meningitis fatality has decreased to one-th abdominal tubercle to one-fifth, and other forms two-fifths of the former rates. The types of n pulmonary tubercle, especially glandular a abdominal disease, are less severe, and bone and jo affections show less tendency to rapid abscess for tion, whilst amyloid disease is now seldom encounter Dr. Macgregor thinks that the abolition of cripp from tuberculosis should be attained, now t the existing provision of 350 beds is increased to 0 beds by the recent opening of the Mearnskirk Hosp for children. Dr. Macgregor suggests that contracting sources of human infection have c tributed to this decline in non-pulmonary tuberculo

but that the pasteurisation of 80 to 90 per cent. of the city's milk may have had a part in the great fall in abdominal tuberculosis. He points out, however, that the sale of designated milks makes very slow headway. The daily sale of milk from tuberculin-tested herds only amounts to 1070 gallons and that of Grade A and pasteurised milk to 1115 gallons. He also cites the conclusion in the 1929 research monograph of the Ministry of Agriculture and Fisheries that the pasteurisation of milk at 145° F. for 30 minutes is not an absolute guarantee that the treated milk is free from the tubercle bacillus, in view of fluctuations in temperature, defects in the plant, and desire to conserve the cream line.

New houses were fewer than last year but have averaged 5500 for the past four years, thus making provi ion for a population of 90,000 during that period. Two-thirds of the houses now erected are three-roomed, and there is a corresponding reduction in larger houses. The "intermediate" municipal houses, with a controlled system of letting for the purpose of relieving overcrowding, are easing the situation, but overcrowding in one-roomed houses has apparently diminished very little since the war. Since 1923 improvement schemes involving 5110 houses have been completed. Another large scheme has been begun, involving a congested area of 22 acres with a population of 5151. The general death-rate in this area has been 22·5, as compared with 17·8 for the rest of the ward with the other mortality figures in proportion. New sites for rehousing within the inner or intermediate zones of the city are becoming scarce and there is a danger of over-building to the exclusion of playing spaces for the children. All dishoused families are offered a new house and about 75 per cent. accept the offer. Subsequently, about 10 per cent. either become weary of making an effort and return to the slums after a brief trial, or are evicted. Most of the remainder do exceptionally well and a definite system of supervision of tenants has been evolved. The benefit to the children by the removal is attested by the headmasters of the schools.

There has been much improvement in the industrial pollution of the air. At the beginning of the century the nuisances reported from 100 observations of chimneys were 17. The present figure is 1·25. The soot falling on the city is 30 per cent. less than in 1914. The classes for the instruction of firemen have been invaluable. Recent observations show that the soot falling on Sundays is 78 per cent. of the amounts falling from Monday to Friday, indicating that domestic smoke is the main factor in air pollution.

Sheffield.

Dr. John Rennie, who was tuberculosis officer and deputy medical officer of health, succeeded Dr. F. E. Wynne after the death of the latter last April, and submits the report for 1929. The birth-rate was the lowest ever recorded in Sheffield and 4·4 less than the average for the previous decade.

The influenza epidemic affected Sheffield less seriously than Glasgow or Leeds. The general death-rate was 1·0 higher than the average for the previous ten years. Of the 3389 notified cases of pneumonia, 318 were removed to the fever hospital. Mild scarlet fever was very prevalent The notifications were 4688. Over 71 per cent. were removed to hospital, where the average duration of stay was 35 days. The deaths numbered 23, a case-fatality of 0·5 per cent. Diphtheria cases numbered 760, of which 94 per cent. were removed to hospital. There were 34 deaths, giving a case-fatality of 4·5 per cent. There were 13 notifications of encephalitis and 12 deaths were registered, chiefly of cases, who contracted the disease in 1924, the year of the severe outbreak. Sheffield's death-rate from tuberculosis was less than that of any of the towns in England and Wales with populations exceeding 200,000, excepting Plymouth, Portsmouth, and Croydon; and was also less than that of England and Wales both for pulmonary and all tuberculosis. This favourable position is attributed to the coöperation of the general practitioners in the scheme, to the provision of adequate institutional accommodation, and to the discovery of early cases by the examination of contacts. The work of the surgical tuberculosis officer, Dr. C. Lee Pattison, and of King Edward VII. Sanatorium has also had a noteworthy effect in securing the early treatment of non-pulmonary tuberculosis. The percentage of deaths amongst grinders from tuberculosis of the lungs has not decreased during the last 44 years. The scheme for rehousing infectious cases of tuberculosis began in 1928. Altogether 59 families have been rehoused under this scheme. Seven of the tenancies terminated after the death of the patient or for other reasons. On Dec. 31st there were 52 families in the scheme. All the members of these families are examined at the dispensary and their homes are visited by the health visitors. The improvement in the health of the families, particularly of the children, the air of well-being and optimism, the cleanliness of the homes, and the brightness of the gardens have been striking features to visitors.

The Joint Smoke Abatement Committee has been extended to include all the neighbouring local authorities except Wortley Rural District Council. An advisory committee, including manufacturers, is carrying out research with a view to lessening the smoke from metallurgical furnaces. The privy conversion scheme has now been completed, and steps are being taken to substitute ordinary w.c.'s for trough-closets and waste water-closets, and to secure the provision of a separate sanitary bin for every house.

Leeds.

Dr. J. Johnstone Jervis reports that the birth-rate was the lowest ever recorded, and that owing to the influenza epidemic in the first quarter, the death-rate was the highest since 1918, and 3·3 above the average of the previous five years. The infantile mortality-rate also shared in the rise, and there were 70 more infant deaths from pneumonia, 13 more from measles, and 15 more from whooping-cough than in the previous year.

The death-rate from influenza and respiratory diseases was 11·99 in the first quarter, as compared with 1·7 for the remaining nine months of the year. The peak week for the influenza epidemic was that ending Feb. 3rd. Scarlet fever of a mild type was also prevalent. There were 3473 cases, of which 3035 were removed to hospital. The deaths numbered 29. Notifications of measles numbered 10,742, and deaths 102. Whooping-cough was also more prevalent and caused 107 deaths.

Regret is expressed that no progress has been made with hospital provision for orthopædic conditions, including surgical tuberculosis. The present position, Dr. Jervis says, is most unsatisfactory and calls urgently for attention. Another unsuccessful attempt has been made to unify the school medical and public health services. Fatal street accidents from motor vehicles were 48 as compared with 53 in the previous year, and the chief constable reports that the installation of automatic signals at crossings has considerably increased the safety of the streets. The notifications of diphtheria were 536 with a case-fatality of 4·8 per cent. Parents have availed themselves but little of the immunisation facilities provided for their children. An unusual outbreak of seven cases of diphtheria among the nurses at the Infants Hospital occurred. The infecting case was a nurse, who resumed duty after convalescence from faucial diphtheria and was afterwards found to have an area of intertrigo behind the ear, which harboured the diphtheria bacillus.

Among the 2975 dairy cows stalled in the city veterinary inspection detected 8 with tubercle of the udder and 6 with generalised tuberculosis. Altogether, including notifications from owners, 33 animals were slaughtered under the Order. The city analyst's report gives instances of cheese becoming contaminated with tin from the foil in which it is

wrapped, and an internal wrapping of grease-proof paper is suggested.

Attention is drawn to many needs in environmental sanitation. Sanitary bins should be substituted for many thousand ash-pits. The common lodging-houses are by no means satisfactory. During the year 49 underground rooms used as dwellings were discovered and 6 cellar dwellings. For all but two alternative accommodation was found. The underground workplaces numbered 341, and include 42 used as offices. Dr. Jervis emphasises the need for legislation to secure better accommodation for office workers. It is ten years since the survey of slum areas was made, but only one small area of 49 houses has been cleared and another partially cleared. There is an alarming increase in houses let-in-lodgings for which, says Dr. Jervis, registration is a purely optional matter. The 7066 municipal houses erected since the war include 524 cottage flats, let at an inclusive rental of 8*s*. to 9*s*., for which there is a great demand. Unfortunately these are on the outskirts and do not provide for slum tenants unable to pay the cost of transport to their work. For such, Dr. Jervis suggests the continental system of large blocks, round open squares with heating, laundry, and other services in common, in the central area of the city.

MENTAL HOSPITAL REPORTS.

The DORSET MENTAL HOSPITAL had 927 patients in residence at the end of last year. The recovery-rate was 36·18 per cent. and the death-rate 7·58 per cent. The general health of the patients was good and there was no infectious disease except a spring epidemic of influenza, which brought with it 20 fatal cases of broncho-pneumonia. The dentist visited fortnightly and treated 210 patients. The laboratory carried out 2382 routine examinations, including a search for typhoid carriers and a systematic examination of the fæces of all patients; four new carriers were discovered and eight carriers of dysentery. The Meinicker micro-reaction for syphilis has been investigated and is to be used as a routine in future, keeping the more complicated Wassermann for confirmation. The hospital records were searched to see if there was any ground for the statement that gall-stones are more common in the insane than in the general population. This was found to be true for patients under 40 years of age, young epileptics being specially liable to cholelithiasis. A leucocyte study has been continued, and Buscaino's black reaction was carried out on all urines. Six general paralytics were treated with tryparsamide, with satisfactory results. The out-patient clinic at Dorchester was held weekly. On the poultry farm an interesting attempt was made to eradicate carriers of bacillary white diarrhœa by means of the agglutination blood test. When once an outbreak of this infection occurs the death-rate is 75 per cent. and about half the survivors become carriers and pass on the disease to their offspring. The farm is to be congratulated, therefore, on collecting 135 doubly tested birds, from which some 1500 healthy chicks have been hatched. As in the past, much attention was given to occupational therapy, and plans for a handicraft room have been approved. A large number of patients were allowed out on trial and on parole. Two female nurses work on the male side and 35 attendants and 19 nurses are certificated or registered.

The CITY OF CARDIFF MENTAL HOSPITAL had 705 resident patients on the first day of this year. The recovery-rate was 44·3 per cent. and more than half of the patients discharged were in residence less than six months—just under a third of them less than three months—so that under the new Act they would escape certification. The general health was good; there was no dysentery and only four cases of tuberlosis and two of erysipelas. The death-rate was 9·12 per cent. New women patients underwent a routine gynæcological examination as part of a piece of research which will be published shortly. All suitable cases had routine examinations of the ear, nose, and throat, and the dental surgeon examined 572 patients. The consulting surgeon performed three major operations. The result of this specialist work is the conclusion that removal of focal sepsis does not necessarily improve the mental state, but that all such lesions should be carefully sought for. In the biochemical laboratory an attempt has been made to study changes in carbohydrate metabolism in psychotics. Results indicate the close relationship between hyperglycæmia (after glucose ingestion) and emotional tension. The oxidative processes in the brain and the relationship between structural intactness and physiological activity in the living cell are being studied. Other subjects under consideration are enzyme action, hæmolytic *B. coli*, and the general relationship between toxæmia and the psychoses. Filter-passing organisms are being sought in schizophrenics, but have not yet been found. The value of artificial sunlight in manic-depressive and toxic-exhaustive psychoses has been studied. The X ray department has served 60 cases, and a large number of routine examinations have been made in the laboratory. General paralysis is treated by malaria and tryparsamide combined. Electrical treatment, massage, continuous baths, and physical drill are provided for suitable cases. Between 60 and 70 per cent. of the patients are kept occupied, and an occupations officer has been appointed. The out-patient clinic at the Cardiff Royal Infirmary is held weekly, and 125 new cases were seen during 1929. A canteen has been started in the hospital, and is so much appreciated that the profits have supplied three new loud-speakers, 14 new gramophones, and 15 dozen records. Parole is granted to 69 men and 94 women, 32 of them into the town. All ground floor wards have open doors and as much freedom is given as possible. A clinical room has been equipped in each ward. The nurses enter for the State examination; during the year four took their final certificate.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 25TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 86 (last week 125); scarlet fever, 2080; diphtheria, 1511; enteric fever, 51; pneumonia, 743; puerperal fever, 55; puerperal pyrexia, 83; cerebro-spinal fever, 10; acute poliomyelitis, 21; acute polio-encephalitis, 2; encephalitis lethargica, 13; dysentery, 9; ophthalmia neonatorum, 79. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 28th–29th was as follows:—Small-pox, 172 under treatment (last week 154 and 3 under observation); scarlet fever, 1769; diphtheria, 2118; enteric fever, 19; measles, 87; whooping-cough, 112; puerperal fever, 17 (plus 5 babies); encephalitis lethargica, 121; "other diseases," 46. At St. Margaret's Hospital there were 14 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 14 (1) from measles, 3 (0) from scarlet fever, 8 (0) from whooping-cough, 25 (6) from diphtheria, 54 (11) from diarrhœa and enteritis under two years, and 42 (8) from influenza. The figures in parentheses are those for London itself.

Hull reported 4 deaths from measles, York 3, and Liverpool 2. Two fatal cases of diphtheria occurred at West Ham and at Swansea. Diarrhœa accounted for 7 deaths at Liverpool, 5 at Birmingham, 2 at Leeds, and 2 each at Manchester, Huddersfield, and South Shields.

The number of stillbirths notified during the week was 254 (corresponding to a rate of 39 per 1000 births), including 46 in London.

CORRESPONDENCE

A CHRISTMAS APPEAL.

To the Editor of THE LANCET.

SIR,—Next month we shall be preparing to give, as is our usual custom, a Christmas gift of 30*s*. to each of our annuitants and to the most necessitous of the grantees. These gifts are looked forward to by many. Some of the regular recipients are blind, others are deaf, and many of them are old and infirm. All are facing the hardships of poverty. Each year the number on our books increases and we need no less a sum than £550 this year if no one is to be left out. I bring this request before your readers in plenty of time before Christmas, because we urgently need money. Where a large donation cannot be given I would ask them not to disregard my appeal, but to send any sum, however small, to the Treasurer, Royal Medical Benevolent Fund, 11, Chandos-street, Cavendish-square, London, W. 1.

I am, Sir, yours faithfully,

THOMAS BARLOW,
President, R.M.B.F.

Nov. 5th, 1930.

CRITICISM OF THE GENERAL PRACTITIONER SERVICE.

To the Editor of THE LANCET.

SIR,—Dr. H. G. Dain, in your report of the recent annual panel conference (THE LANCET, Nov. 1st, p. 972), is recorded as saying, during some remarks upon the increase of sick benefit and the adverse criticism of such increase by the National Conference of Friendly Societies: "it was unfortunate that such people as Dr. Graham Little and Lord Riddell should make statements without actual basis in fact. The service given to the panel patient was the best type of general practitioner medical service in the world." I am entirely at a loss to understand Dr. Dain's reference to me in such a connexion, and I must ask him to specify statements made by me "without basis in fact." In an article which I contributed to the *Edinburgh Review* in January, 1929, discussing the National Health Insurance Act, I wrote:

"The majority of medical men in this country are engaged in the medical service of the panel. The general practitioner is in fact the panel practitioner. The qualifications, competence and status of the general practitioner have improved enormously in our own time, more especially during the 17 years which have elapsed since the Insurance Act came into being. There is no better general practitioner in the world than the British general practitioner, and no criticism could be directed against his capacity to deal properly with insured persons if that capacity were not in fact restrained and hampered by bureaucratic regulations and by difficulties inherent in the circumstances of the Act . . ."

My criticism of the Act, then and subsequently, has been chiefly directed to its administrative, not to its medical defects. In two recent addresses to general practitioners (the Paddington Medical Society, on Sept. 9th, and the Guildford Division of the British Medical Association, on Oct. 9th, reported in the *Medical Press and Circular* of Sept. 17th and Oct. 22nd respectively) I deprecated the proposal of the Council of the British Medical Association to ask for an extension of the National Health Insurance Act to dependants, my objection being grounded on (1) the menace to private practice which a universal panel practice would imply, and (2) the encouragement which such a request, made at the present moment by the medical profession, would give to that political party which ardently desires to establish a State medical service. I pointed out, also, that a more inopportune time for preferring this request could hardly have been chosen, in view of the chorus of dissatisfaction with the present conditions of national health insurance, as recently voiced by bodies so representative of the insured population as the Trades Union Congress and the National Conference of Friendly Societies.

I submit, Sir, that if the profession is going, as the B.M.A. Council wishes it to do, to ask for an extension of national health insurance, which it would cost at least ten million pounds a year to provide, it is not unimportant to ascertain whether those for whom it is to be provided, and who must find the money, really desire that provision. Neither the B.M.A. Council nor the panel conference is in a position to force these proposals upon the nation if the nation is unwilling to accept them. The tone of the comments made at the panel conference on the reprehensible dislike that is shown by insured persons for some of the conditions of the service now provided reminds me of a similar attitude adopted by the celebrated Prussian historian, Prof. Delbruck. In a conversation with him at dinner in the year 1913, discussing different conceptions of colonial government, I mentioned that I knew of many German settlers who had migrated from German South-West Africa to British South Africa because they did not like the military rule exercised in the German colonies. Delbruck was very angry. "I know that," he said, "but it is for the good of the Fatherland that Germans remain in German territory and" (here he thumped the table) "they *shall* like it." The chairman of the B.M.A. Council and the chairman of the Insurance Acts Committee treated the recent conference like the mere puppet of the Association, which it has, in fact, become. As a prominent member of the conference quite correctly put it: the conference has come to regard the Insurance Acts Committee of the B.M.A. as the "executive" of the conference, and the Insurance Acts Committee, in turn, is ruled by the B.M.A. Council. Small wonder, therefore, in these circumstances that the conference says ditto to the council. The voice is the voice of Jacob, but the hands are the hands of Esau and, like Esau, the B.M.A. Council is selling the doctor's birthright, his professional independence, for a mess of pottage. But if the B.M.A. Council, when it approaches Parliament for an addition to the estimates of ten million sterling a year, is going to maintain the Prussian mood of meeting criticism displayed by the conference under its tutelage, we who deprecate the imposition of universal panel practice can sleep in our beds.

I am, Sir, yours faithfully,

E. GRAHAM LITTLE.

House of Commons, Nov. 3rd, 1930.

HÆMATOPOIETIC PROPERTIES OF DRIED MILK.

To the Editor of THE LANCET.

SIR,—In his unstinted and exclusive praise to the American investigators on this subject (THE LANCET, Nov. 1st, p. 957), Mr. A. L. Bacharach has done an injustice to the brilliant work of a British scientist. An investigation occupying a period of over two years on over 500 babies was carried out by Dr. Helen Mackay [1] on the same problem, and with far more

[1] Arch. Dis. Children, 1928, iii., 117.

practical and definite results. The complete omission of any reference to this pioneer work is unfortunate. A consideration of the results of the former investigation which was carried out not on babies but on five albino rats would seem to indicate that the medicated dried milk used was deficient in some way, as growth was not as good as on liquid milk. Further, it would also appear to be indicated that the dose of iron salt (name not mentioned) was low, inasmuch as the hæmoglobin percentage dropped consistently after the third week. In Dr. Mackay's research both growth and hæmoglobin percentage were maintained high. I am, Sir, yours faithfully,

Grosvenor-street, W., Nov. 3rd. HAROLD TAYLOR.

CHRONIC NASAL SINUSITIS.

To the Editor of THE LANCET.

SIR,—While appreciating your full review of my recently published monograph on "Chronic Nasal Sinusitis and Its Relation to General Medicine," I propose to comment on the statement that the author "reports cases of this disease (nasal sinusitis) which have recovered after exploring the sphenoidal sinus, a circumstance by now very well known, but does not explain that many cases recover either spontaneously, or after removal of part of a middle turbinal. It is thus possible . . . that a particular patient would have recovered without any intervention. This criticism may be extended to the chapters on other regions. . . ."

Maybe one must not expect the reviewer to read every page of the book he reviews, but, at any rate, on one point my teaching is the converse of what your reviewer criticises. Indeed, not once, but over and over again the importance of recognising the tendency to spontaneous recovery is stressed, as for example, in the following paragraphs :—

"We have already emphasised the frequent tendency to spontaneous recovery from sinus infections and their secondary infections, although this applies much more to the acute than to the chronic infections. And the problem that must ever recur is when to rely on this tendency to recovery, and when to operate, for while unnecessary interference is to be discouraged, ill-judged expectancy may be fraught with very grave consequences" (p. 171).

"As regards retinal and other ocular metastases, Sir John Parsons notes the strong tendency for endogenous bacterial metastases to undergo spontaneous resolution" (p. 46).

"Fortunately there is such a proclivity to spontaneous resolution of the low-grade metastasis that the persistent activity in the primary source of infection almost appears essential; (1) To the initial penetration of the organisms slowly traversing the lymph channels . . . ; (2) To the maintenance of a once formed metastasis, be it . . . retinal, &c." (p. 46).

Again, having cited cases of optic neuritis proved to have been due to sphenoidal sinus infection, and illustrated sections showing the actual organisms of sepsis in an optic nerve sheath, one continues :—

"But it must not be inferred that such conditions are always consequent on focal sepsis," &c. (p. 104).

"The co-existence of nasal disease with orbital ocular disease which might be rhinogenous does not of necessity prove any causal relationship, for it is always possible to have long standing and extensive nasal accessory sinus suppuration side by side with even the severer type of orbital infective inflammations, and yet the infection of the two regions may be due to quite independent sources of infection" (p. 100).

"In some cases the primary source of ocular infection is far removed from the head, perhaps in the gall-bladder or in the large intestine" (p. 102).

Your reviewer complains that I omitted to state that "cases of sphenoidal sinusitis recover after removal of part of the middle turbinal. It is thus possible that the local blood-letting acts beneficially."

I am glad that no such suggestion finds support in my book, but on p. 106 attention certainly was drawn to experiences related more than 30 years ago :—

"e.g. H. M. Fish, referring to retrobulbar neuritis emphasised the fact that he had had several cases in which, although there was no nasal discharge, and the nasal examination was absolutely negative save for a slight hyperæmia, he had relieved the ocular symptoms by simply draining the sinus" (p. 106).

The need for precise diagnosis led me to devise, more than 30 years ago, the methods I advocate, to prove which sinus is infected and to drain and disinfect it, instead of merely doing just something in the way of blood-letting, particularly on an inoffensive middle turbinal; for such crude procedures should be discouraged.

I am, Sir, yours faithfully,

Clifton, Bristol, Nov. 3rd. P. WATSON-WILLIAMS.

A MEDICAL SERVICE FOR THE NATION.

To the Editor of THE LANCET.

SIR,—In answer to Dr. Bodman, I maintain that it can be maintained that at birth all are equal. Not, of course, meaning that every human animal is identical at birth, but that every Englishman comes from equally good stock and stands the same chance of having had a good ancestry, whatever the financial position or social status of his immediate forbears may have been.

We cannot argue from a single individual; in the study of heredity we must consider large numbers over periods of time. Take, for instance, the Londoner. For many years Sir Arthur Keith tried to find a Londoner to the third generation; that is one born in London, his two parents and his four grandparents. I took up the search. I inquired all over London, among friends and acquaintances, from patients, both in private and hospital practice. I thought I had found some at the tip of the Isle of Dogs when called to see an old lady of 70 who was still living in the cottage in which she was born, but no! Of her grandchildren one grandparent was a peasant up from the country. After four years I found at Clapham the child of a gas-fitter and at Balham two daughters of an engineer who came in Sir Arthur's category. All the rest gave the same history, someone of yeoman or peasant stock up from the country in the last or previous generation. Take again the county families. Family trees consider the male, and only just mention the woman. Yet for our purpose she is as important, and in every alternate generation different blood is brought into the old stock thereby. Among the titled nobility the change of blood is a constant theme of Disraeli in his novels :

"In a commercial country like England, every half century develops some new and vast source of public wealth, which brings into national notice a new and powerful class. A couple of centuries ago, a Turkey Merchant was the great creator of wealth; the West Indian Planter followed him. In the middle of the last century appeared the Nabob. These characters in their zenith in turn merged in the land and became English aristocrats; . . . The expenditure of the revolutionary war produced the Loanmonger . . . and the application of Science to industry developed the Manufacturer, who in turn aspires to be 'large acred.'" ("Sybil," Bk. II., Chap. 7.)

No one can say that this process has diminished in the 85 years since "Sybil" was written. Just as we of the professional classes are constantly moving into "the nobility and gentry" so we are constantly interchanging with the "worker." If we go into it we find that a grandmother was a dairymaid and that the coal-merchant great-grandfather began as a waterman when the Thames was still a highway.

A couple of years ago I dipped into the biography of a peer who though the first of the title had four surnames. He boasted of his descent from Charlemagne and thought that one who had this blood in his veins was better fitted to rule the nation than those who had not. So I took out a pencil and on jotting it up thought that in all probability I, too, had the blood of Charlemagne in my veins. By allowing four generations to the century I found I had 3,747,774,640,448 ancestors when he was crowned. Allowing for the same ancestor cropping up twice quite a number of times it would still leave them as numerous as the population of Western Europe on that day. But in heredity what are 41 generations? We have to go back, not to the time of Charlemagne, but to that of the Long-Barrow and the Beaker folk and to consider all the migrations of peoples into our islands since those times. The factors of heredity may "influence very largely the potentialities for disease"; but they do so equally throughout the nation.

When I made the statement that at birth all are equal, I was referring to the physical characteristics, but I will accept Dr. Frank Bodman's challenge and include the mental ones. Of moral ones he will probably agree with me that we have no data upon which to study hereditary factors uninfluenced by the disadvantages either of great wealth or of extreme poverty and the other environmental factors that must influence all before character is developed. There is no reason to suppose that more are born "with fewer neurones than the normal baby" from any one group of the community than from any other; whether you subdivide this community into the upper and the middle and the lower classes, or whether you divide them into the rich, the comfortable, and the poor. Nor are there any statistics to show that there is more mental disease among one of the groups beyond such as can be accounted for by greater stresses causing the mentally unstable to topple over into disease. We see the same with the physical characteristics, whether one is delivering the child of a Yorkshire peasant or the babe of a tuberculous mother in a Bermondsey backyard, they are the same children; and they are the same as those that are born to middle-class parents or in the ancestral home. We hardly realise how soon the effect of environment acts upon this babe. A few days' loss of weight may not matter, but a few weeks of different fare does, and by the end of two years the damage is done. Any one can recognise in adult life the poor teeth of which the crowns were laid down in these two years. Biochemistry has not yet advanced enough to recognise similar differences in the other tissues laid down in the same period. Yet we have every reason to believe they exist in these as well as in the rickety bone that becomes again absorbed.

There is no question of "sentimental consideration"; a proper answer to this question of physical quality at birth is a basis of all our work—hospital work, social-service work, antenatal clinics, care committees, school clinics, all the advances in sanitation and hygiene of the last century, housing, town planning. To a large extent they all depend upon it. If the answer is in the negative much money is thrown away; but the answer is not in the negative. From the experience of 25 years in medicine I do not believe that there is "taking place a relative increase of physically and mentally inferior people." I see no sign of deterioration among the well-to-do, and among the poor I see a very great improvement upon their condition from that I remember when I first became a medical student. There is still a great difference between the two: I repeat that it is the function of the State to eliminate the factors that make this difference. I base our justification for this on the fact that at birth we all are equal, in the sense which I have defined above and which was inherent in the context when I made the statement previously.

I am, Sir, yours faithfully,

Queen Anne-street, W., Nov. 3rd. T. B. LAYTON.

A RUSSIAN CANCER INQUIRY.

To the Editor of THE LANCET.

SIR,—In the interest of science I beg you to insert an appeal to my medical colleagues in your country whose addresses it is impossible for me to determine.

I am, Sir, yours faithfully,

Prof. Dr. N. I. KOUCHTALOFF,
Director of the Obstetric and Gynæcological Clinic at the Medical Institute of Astrakhan, U.R.S.S.

The appeal is as follows:—Having been invited by the organisation committee of the Ninth Pan-Russian Congress of Gynæcologists and Obstetricians, which will take place in Moscow in September next, to deal with the medical treatment of inoperable cancer of the uterus, I should be glad, in order to clear up the question as far as possible, to learn your experience on the subject. The campaign against cancer takes on more and more a world-wide aspect. All the medical sciences are called to coöperate in the study of tumours to which humanity still pays so vast a tribute in spite of the application of chemistry, physics, cytology, and clinical surgery. I beg you, therefore, to fill in this inquiry form.

QUESTIONAIRE.

1. Name of establishment, hospital, or institute.
2. Methods of treatment of inoperable cancers (surgical, chemical, physical, biological, &c.).
3. Their effects and results.
4. Medical treatment.

Date.	Serial No.	Age.	Microscopic diagnosis.

Substance employed.	Method of application.	Results.	
		Immediate.	Ultimate.

5. Your opinion.

The replies will be published over the names of their authors.

LAXATIVES AND COLITIS.

To the Editor of THE LANCET.

SIR,—It would appear from Dr. Spriggs's letter that I have too closely identified him with the prevalent view that paraffin is the drug par excellence in conditions of intestinal stasis, and I must offer him an apology. The experiments (2426 and 2731) quoted by Dr. Spriggs support the view that liquid paraffin, in small and medium doses, does not cause wasting. Experimental evidence of this nature is more cogent than microscopical demonstration that the paraffin in fæces is distributed as an emulsion and

not as a film, with the inference that the digestion of foodstuffs is not interfered with in this way. Parenthetically, one might point out that the quantities of paraffin administered in these experiments—1 oz. daily in No. 2426, and ½ oz. daily (in the form of jelly) in No. 2731—have often to be exceeded in practice; it would be interesting to learn the results obtained in similar experiments on the absorption of foodstuffs when larger quantities of paraffin are used which, as the references quoted by Dr. Spriggs indicate, lead to film formation.

After repeated trials and failures one wonders how often diet and exercise, without drug help, really do correct constipation. I feel certain that the general experience of practitioners in this regard cannot be a rosy one. The observance of a daily effort at defæcation at a fixed time can be religiously carried out, but the "skeletal muscles and nervous reflexes employed in defæcation" (I quote Dr. Spriggs) refuse to respond. The general view of the laxative action of paraffin appears to be that it acts purely as a lubricant. Experience makes one question this. It is probable that every laxative bears a general resemblance to every other laxative in that it acts by stimulation of the structures of the bowel wall and, on the other hand, varies from all other laxatives in possessing a peculiar mode of stimulation, and I believe that paraffin acts similarly. If paraffin were to act through lubrication the film theory would need to be assumed, and this has been disproved by the experiments quoted by Dr. Spriggs. If, on the other hand, it becomes emulsified in the fæces and causes them to hold more water than normally it would appear to act by reflex stimulation of the bowel wall by a bulky residue, and it is probable that it stimulates the bowel wall in other ways.

There is, then, no a priori reason why paraffin should replace other laxatives, as all laxatives act through stimulation. I have met with one or two patients who have complained of abdominal soreness after the use of paraffin, and I have found tenderness along the course of the colon, which I have concluded was due to irritation by paraffin.

I am, Sir, yours faithfully,

South Tottenham, N., Nov. 1st. L. J. GREEN.

TOXICITY OF VITAMIN D.

To the Editor of THE LANCET.

SIR,—We have read with great interest Dr. Duguid's article last week (p. 983) on this subject, which is all that a survey should be. There is now no doubt that very large doses of irradiated ergosterol may have definitely toxic effects on experimental animals receiving certain kinds of artificial diet. Windaus, indeed, uses the minimum lethal dose for mice, as well as the antirachitic dose for rats, to control various experimental irradiation products. It is of interest to note that the former is from 5000 to 10,000 the latter, in spite of the size of the mouse, which is smaller and presumably correspondingly more sensitive than the rat. This enormous gap between therapeutic and toxic dose—far greater, for example, than with the alkaloids—gives clinicians an ample margin of safety, as Dr. Duguid points out. It does not, however, remove the necessity for physiological standardisation of the vitamin D in all medicinal products containing it.

Manufacturers in this country to-day without exception realise this necessity. We ourselves, although first concerned with the preparation and distribution of a vitamin D concentrate as long ago as 1924, realised the necessity from the beginning, and in our own laboratories more than 5000 physiological assays of vitamin D have been carried out during the past six years. Until recently, however, we were compelled, as were the American firms to whom Dr. Duguid refers, to speak in terms of cod-liver oil. This was by no means satisfactory, for, as one of us has previously shown in your correspondence columns,[1] the variation in vitamin D content of cod-liver oils is very great.

Following the recent report of the Committee on Accessory Food Factors it will certainly not be long before all preparations produced by reputable firms will be described in terms of this unit. A short time must, however, elapse for the checking up of existing units and standards against the official preparations. When this measure of coördination has been achieved, the "authoritative pronouncement on the proper dosage for therapeutic purposes," for which Dr. Duguid so rightly asks, will, we hope, occupy the attention of the Medical Research Council.

We are, Sir, yours faithfully,

H. JEPHCOTT,
Director,
A. L. BACHARACH,
Glaxo Research Laboratory, N.W. 1. Chief Chemist.

CIRRHOSIS FROM MANGANESE.

To the Editor of THE LANCET.

SIR,—Dr. G. M. Findlay draws our attention to the fact that he described the experimental production of liver cirrhosis by manganese salts in the *Brit. Jour. Exp. Path.* (1924, v., 92) some years before the Hursts, to whom we ignorantly (p. 959 in your last issue) attributed the discovery. We apologise.

We are, Sir, yours faithfully,

A. E. BOYCOTT,
G. R. CAMERON.

University College Hospital Medical School, Gower-street, W.C., Nov. 3rd, 1930.

THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—I desire to remind registered medical practitioners that if they desire to have a new address entered in the forthcoming Medical Register they should communicate with me without delay. I should also like to take the opportunity of pointing out that the Medical Register is the statutory publication. It is the appearance of a name in this book alone which makes a practitioner legally qualified, and it should not be confused with other books of a similar nature which are purely private publications.

I am, Sir, yours faithfully,

NORMAN C. KING,
Registrar, General Medical Council.

44, Hallam-street, Portland-place, W., Nov. 4th, 1930.

[1] Jephcott, H., THE LANCET, 1928, i., 261.

STANDARDS FOR JAM.—As from the beginning of November the jam manufacturers are setting up a standard for their products, which will be classified as either of first or second quality, and will be conspicuously labelled either "full fruit standard" or "lower fruit standard." The initiative has been taken by the manufacturers themselves. In the case of mixed jams the fruit named first on the label will be present in greater proportion, thus "plum and apple" will contain more plum than apple.

PANEL AND CONTRACT PRACTICE

Efficient Rural Service.

THE opinion has been recently and repeatedly expressed that the results of National Health Insurance practice are more satisfactory in the country than in the towns.

"If this is the case," writes Rural Panel, "it might be worth while, at a time when a large extension of insurance work seems to be contemplated, to look more closely into the matter. There are certain special features common to all medical practice in rural districts as opposed to that in towns. First, the population is always a socially and financially 'mixed' one. They are not all rich or all poor. Secondly, the population is more stable; houses are not constantly changing tenants and a far higher proportion of people live and die in one place. Thirdly, country people are notoriously of a more conservative nature than townsfolk; their ideas change less quickly. Fourthly, large hospitals and consultants are much more difficult of access. Fifthly, there is the obvious fact that the distance between patient and doctor is greater.

"How do these considerations affect panel practice? In the first place a socially mixed population ensures that all rural practitioners must be 'on the panel.' Thus, there can be no 'inferior' class of doctor who only attends the poor, and the labourer knows that his own doctor may be going on to see the Lord of the Manor next on his list. This naturally increases his respect and also reacts on the doctor, who is kept up to scratch by having educated patients to deal with as well as the slower witted labouring classes.

"A stable population has obvious advantages from the medical point of view. It means that the phrase 'family doctor' really has some significance and is not a mere synonym for 'medical shop-walker.' There is a much greater chance of patients becoming friends of the doctor as well as patients, and it cannot be a disadvantage for a patient to be able to say 'I've known Dr. So-and-so for 30 years and I have every confidence in him because he knows my constitution.' Again it is only in human nature that a doctor who knows that if he sets old John's leg badly he will see him limping past his window every day for the rest of his life will take more trouble to obtain a good result than if he is merely one of a crowd or a number on a card.

"The conservative nature of the rural mind shows itself in many ways, most of which tend to improve the relations of doctor and patient. The word 'Sir,' and what is now called an old-world politeness, may mean nothing, may even be a sign of a regrettable lack of education in class-consciousness in a backward proletariat, but they certainly grease the wheels of intercourse and increase the amenities of life. A horror of chopping and changing makes the country-man very loath to change his doctor—always a regrettable occurrence—nor does he lightly follow after false gods in the shape of the latest 'discovery' of the popular press, nor pester his doctor to procure him their images to worship. Care, kindliness, and skill impress him more than an array of 'gadgets.'

"The comparative inaccessibility of consultants and large hospitals may be detrimental to the patient, but it is, undoubtedly, good for the country panel doctor. It makes him self-reliant and resourceful; forces him into a working knowledge of every branch of his subject and gives him a pride in his cottage hospital and the work it can do. A man who had not been a success in a country village was asked by a colleague why he was going to London. His reply was that in town if you didn't know what was wrong with a patient he could always be sent into hospital.

"Lastly, the greater distance which the doctor has to travel to see his patient is realised by the great majority of the patients and results, on the whole, in a diminution of unnecessary calls. There is, of course, a higher ratio of visits to cases seen in the surgery than in the towns, but while this may increase the doctor's working hours it means that surgeries are less crowded and there is less tendency to do bad work. It is also, perhaps, not too much to suggest that the quiet interval occupied in driving from one case to another may give the doctor leisure to consider each case a little more thoroughly. Again, the mileage allowance, inadequate though it still is, is to some extent a compensation, whereas the minimum fee paid by a poor private patient is often all the practitioner can expect for a ten-mile drive.

"There is, of course, the reverse of the medal. The telephone allows large householders to summon medical aid for their domestics at any hour and for any cause, reasonable or unreasonable, nor dare the doctor charge for such a visit even when requested to do so by the householder. Should maid and mistress subsequently fall out, he may find himself 'court martialled' under a grave charge. A stable population means that one person with an unjust grievance may turn a whole village against the doctor. The conservative mental outlook means that a greater amount of time must be spent in explaining the why and how of treatment: a country doctor who doesn't give 'a bottle of medicine' would lose his practice in very quick time. Finally, the routine—and often unnecessary—visits laid down by the authorities for certificate-giving purposes press very hardly when each involves a 20-minute journey by car.

"Still, taken as a whole, the above considerations seem to show that the special features inherent in country medical practice tend to improve the panel service as compared to the conditions in urban areas. It must not be forgotten that the points of view of the doctor and of the patient are not opposing ones, but are essentially similar. The aim of any scheme of medical service must be to secure efficient medical attention for its members, and thus it must not, on the one hand, make the lives of the many devoted and efficient doctors unbearable by placing them under intolerable conditions, either of too great dependence on their patients' whims, of inadequate financial rewards, or of the impossibility to do good work, nor, on the other hand, must it fail to safeguard its patients from the small minority of doctors who may be careless or inefficient.

"At present," it seems to Rural Panel, "this aim has been achieved by National Health Insurance practice in the country districts at least."

Uninformed Criticism of Insurance Practice.

In our report last week (p. 972) of the panel conference under the heading of "A Direct Attack" we recorded briefly a refutation of the misleading and exaggerated statements about insurance practitioners made at the autumn conferences of friendly societies and trade unions. We are glad to reproduce

the full text of the remarks of the chairman of the Insurance Acts Committee as given in the *British Medical Journal*. During this autumn session of conferences relating to national health insurance there appeared to have been, said Dr. Dain, a larger amount of virulent abuse poured out upon the insurance practitioner than had fallen to his lot for a good many years. It was perfectly easy for the president of the National Conference of Friendly Societies to get up and make statements when he knew there was no doctor present to challenge them, and thus these statements got a start. It appeared that the matter which had hurt the friendly societies most was the increase in sickness claims, and as they must have a scapegoat, they had fixed upon the doctor, and had drawn the most absurd conclusions from the figures presented to them. He wanted to put it to the conference that these were false deductions. Last year there were 410,000 cases referred on the ground of incapacity; the number actually examined was 211,000, and apparently the assumption was made that the rest—nearly 200,000—were people who had been improperly certified. That, of course, was an absurd assumption. It had always to be remembered that in the interval between the insurance practitioner's examination and the examination by the regional medical officer the patient in a very large number of cases was becoming increasingly fit for work. Of the 211,000 examined, only 67,000—or 16 per cent. of the total number referred—were found to be not incapable of work. The doctor's diagnosis was only reversed in 16 per cent. of cases, although the factor of time was always operating, so that these people were getting nearer and nearer to the time when they would be well. He believed that if an actuary examined the figures he would find that the number of people returned to work on account of the action of the regional medical officer who would not have been returned to work but for him was a very small number indeed.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

Private Members' Bills.

AMONG the notices of presentation of private members' Bills, given in the House of Commons on Oct. 31st, were the following:—Dr. ETHEL BENTHAM—Bill to amend the law relating to the nationality of women; Mr. LLEWELLYN-JONES—Bill to grant complete or partial relief from rates in the case of certain hereditaments used for the purpose of hospitals, infirmaries, dispensaries, convalescent homes, nursing homes, sanatoria, and other similar uses, or in connexion therewith; Dr. VERNON DAVIES—Bill to amend the law with respect to regulation of advertisements.

HOUSE OF COMMONS.

THURSDAY, OCT. 30TH.

Health in the Baking Industry.

Mr. THORNE asked the Home Secretary whether he had received a letter from the Essex County Association of Master Bakers, asking for legislation to safeguard the health of those engaged in the industry and to restrain those who practised methods of trading uncalled for by the public and detrimental to the welfare of the community; and what action he intended taking in the matter.—Mr. CLYNES replied: The letter to which my hon. friend refers suggested a stricter enforcement of the existing law with regard to Sunday baking and delivery of bread, or preferably fresh and more effective legislation. The matter is regulated at present by the Bread Acts of 1822 and 1836, but the enforcement of these Acts is not a matter for which my department is responsible, and I have no power to intervene. It is open to any person aggrieved, or any member of the public to take action. As regards fresh legislation, I should, of course, be willing to consider any proposals that might be submitted, though I can see little prospect at present of the Government being able to find time for any Bill on this subject.

Workmen's Compensation.

Mr. BOYCE asked the Home Secretary whether the Government had under consideration the question of introducing legislation dealing with workmen's compensation; if so, whether any steps had been taken to consult with employers' as well as workers' organisations in order to ascertain the probable effect on industry of any measures which might be in contemplation; and, if the views of these organisations had not been obtained, would the Government give them an opportunity of considering any proposed legislation on this subject before its introduction into Parliament.—Mr. CLYNES replied: The question of legislation is under consideration, but I am not in a position at present to make any announcement. The hon. Member may be assured that before legislation is introduced the employers' as well as the workers' representatives will be consulted.

Slum Clearance and Re-Housing Schemes.

Mr. GRAHAM WHITE asked the Minister of Health the number and scope of slum-clearance and re-housing schemes so far approved under the Housing Act, 1930.—Mr. GREENWOOD replied: I have received resolutions declaring 11 areas to be clearance areas, one clearance order, and one compulsory purchase order. The number of persons occupying the 11 areas is approximately 5400.

Housing Progress.

Mr. SIMON asked the Minister of Health the number of houses completed under the Housing Act, 1924, in each year ending Sept. 30th, in England and Wales, from the passing of the Act to the present time, and what further houses, if any, were built during each year to be let at rents within the capacity to pay of the working classes.—Mr. GREENWOOD replied: The following statement gives the particulars asked for in the first part of the question and shows the number of houses completed during the year in England and Wales with State assistance under the Housing (Financial Provisions) Act, 1924:—

Year ended Sept. 30th—	Houses.	Year ended Sept. 30th—	Houses.
1925	12,385	1928	53,792
1926	46,489	1929	53,516
1927	97,316	1930	51,310

I regret that I am not in a position to supply particulars sought in the latter part of the question.

Treatment of Maternity Cases.

Sir BASIL PETO asked the Minister of Health what steps he intended to take to carry into effect the interim report of the departmental committee for the improvement of accommodation and treatment of women in childbirth, particularly in cases of tuberculous patients; and whether arrangements could be made for all such cases, from whatever authority, to be sent to such sanatoria as had facilities for the reception of pregnant women.—Mr.

GREENWOOD replied: I propose, in the first instance, to communicate with the local authorities in regard to certain of the recommendations in this report, including the provision of additional accommodation for women in childbirth. As regards the second part of the question, I understand that special arrangements for confinement are not usually made in tuberculosis sanatoria, and I am advised that it is generally preferable to arrange for the transfer of pregnant women in sanatoria to a maternity home for the confinement and to readmit them subsequently to a sanatorium.

National Health Insurance.

Mr. FREEMAN asked the Minister of Health whether he contemplated making any change in the administration of the national health insurance scheme so as to include adequate dental treatment for all contributors.—Mr. GREENWOOD replied: No such change as is referred to by my hon. friend is in contemplation at the present time. I may point out that already approved societies with an aggregate membership exceeding 80 per cent. of the total insured population are providing dental treatment for their members as an additional benefit.

Ex-Service Men and the Seven Years' Limit.

Major OWEN asked the Minister of Pensions the number of applications for pensions and treatment received from ex-Service men who were disqualified under the seven years' limit; how many of these had been considered; and how many claims had been granted. Major COHEN asked the Minister of Pensions the total number of claims submitted outside the seven years' time limit that had been recognised by the Ministry up to Sept. 30th, 1930, under the following headings: recognised by the provision of treatment and recognised by a grant under special sanction, respectively.—Mr. F. O. ROBERTS replied: The total number of fresh applications made since my announcement in November last were, up to the end of September, about 18,000, a majority of which were, however, received in the first few months of this period. Some 14,500 had been considered and dealt with by that date for most of which, I fear, little or no evidence was furnished or could be obtained in their support. About 800 of these applications were ascertained by the Ministry to be well founded, and of these, 20 were found to need no more than a brief course of surgical treatment, while the remainder received compensation by way of pension or other pecuniary grant.

Poison-gas Experiments.

Lieut.-Colonel MOORE asked the Secretary for War whether his attention had been drawn to the reports in the press in regard to the work carried on at the research station on Salisbury Plain; if any, and, if so, how many, old horses were handed over for experiment in poison gas and in plague bacteria cultivation; and what action he proposed to take to stop such activities on the part of the Government.—Mr. T. SHAW replied: My attention has been drawn to certain statements reported in the press to the effect that 2000 old horses have been handed over to the experimental station at Porton for experiments in poison gas and the cultivation of bacteria for spreading plague. The facts are that during the period from 1921 to 1930 only 25 horses in all have been used for experiments at Porton in connexion with poison gas but no horse, or indeed other animal, has been used at Porton for experiments in plague bacteria cultivation. I am advised that the experiments carried out were to enable data to be obtained for preventive and curative treatment in the case of horses affected by poison gases.

Sir ROBERT GOWER asked the Secretary for War what steps were taken to prevent suffering on the part of horses and other animals subjected to poisonous experiments at Government and other experimental stations in Great Britain; and whether he was satisfied that no such suffering took place.—Mr. T. SHAW replied: The officers holding vivisection licences for carrying out poison-gas experiments at the War Department Establishment work in strict conformity with the provisions of the Cruelty to Animals Act, 1876. The terms of these licences ensure that no unnecessary suffering is caused to the animals.

Experiments on Living Animals.

Mr. FREEMAN asked the Home Secretary how many experiments were conducted last year on living animals when inspectors were present and how many in their absence; and who decided whether an animal was suffering pain when no inspector was present.—Mr. CLYNES replied: As to the first part of the question I would refer my hon. friend to the answer given on July 3rd last. With regard to the last part, each holder of a licence is made responsible for seeing first that any animal which is suffering pain that is either severe or likely to endure is at once killed if the main object of the experiment has been attained: and, secondly, that any animal that is suffering pain both severe and likely to endure is at once killed in any case. The requirement is made a condition of the licence and any infringement of it brought to my notice would be severely dealt with. The Home Office Inspector informs me that he is satisfied that the condition is scrupulously observed by the holders of licences.

A Health Insurance Claim.

Mr. MUFF asked the Minister of Health if he would inquire into the reasons why national health benefit was withheld by the Royal Liver Approved Society to Stephen Rose, of 104, Balfour-street, Hull, after he had been certified by his doctor for benefit.—Mr. GREENWOOD replied: I have inquired into this case, and am informed that, on receipt of the benefit claim, the Approved Society found it necessary to ascertain whether the member's illness was due to an accident for which he had previously received compensation under the Workmen's Compensation Act. The Society have now satisfied themselves that this is not the case, and I understand that the benefit due was paid on Oct. 28th.

Local Supervision of Midwives.

Mr. MUGGERIDGE asked the Minister of Health what was regarded as the minimum number of midwives required to be in service in a district before the council of the district might be constituted the local supervising authority under Section 62 of the Local Government Act; and, in view of the dissatisfaction in the urban district of Dagenham, where 23 midwives were employed, of whom 19 resided in the district, he would reconsider his refusal to make an order directing that the urban district council shall become the local supervising authority.—Mr. GREENWOOD replied: The number of midwives practising in a district is not the only consideration to be taken into account in deciding whether the council of the district should be constituted the local supervising authority under the Midwives Acts. In the case of the urban district of Dagenham, I came to the conclusion that it would be premature to give these powers and duties to the district council having regard to the recent constitution of the council and its brief experience in administering maternity and child-welfare services, and I should not feel justified in reconsidering that decision.

TUESDAY, NOV. 4TH.

Experiments on Dogs.

Sir ROBERT GOWER asked the Home Secretary whether it was his intention to introduce a Bill to make illegal painful experiments upon dogs during the present Session of Parliament.—Mr. Clynes replied: The answer is in the negative.

Death-rates in Scotland.

Mr. MARCUS asked the Secretary of State for Scotland the separate death-rates amongst men, women, and children in Scotland in the years 1927,

1928, and 1929.—Mr. JOHNSTON replied: The following statement gives the death-rate per 1000 in Scotland in the case of males and females of all ages and children under 15 years respectively:—

	1927		1928		1929	
	M.	F.	M.	F.	M.	F.
All ages	14·07	12·89	13·87	12·85	15·09	13·99
Under 15 years ..	11·9	9·6	11·8	9·7	12·0	9·4

Physique of Military Recruits.

Mr. T. SHAW, Secretary for War, in reply to Major GLYN, said that from July 1st to Sept. 30th, 1930, 10,447 men were served with notice papers for enlistment in the Foot Guards and Infantry. Of this number 6,506, or 62 per cent., were rejected on medical or physical grounds.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. W. Greaves, R.N.V.R., to be Surg. Lt.

The following appointments are notified:—Surg. Lts. G. Phillips to *Vivid*, for H.M. Dockyard, Devonport; and H. Lee-Duncan to *Mantis*.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. A. J. Beard to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Lts. to be Capts.: A. McMillian and W. G. S. Foster.

Lt. P. W. A. Agnew resigns his commn.

ARMY RESERVE OF OFFICERS.

Lt.-Col. J. D. Bowie to be Lt.-Col.

TERRITORIAL ARMY.

Lt.-Col. R. Errington to be Bt. Col.

Maj. G. J. Linklater to be Lt.-Col. and to comd. 155th (Lowland) Fd. Amb.

Capt. T. E. Hastings (late 5th Bn. Inniskilling Fus.) to be Lt., and relinquishes the rank of Capt.

ROYAL AIR FORCE.

Flying Officer P. J. McNally is granted a permanent commission in this rank.

Dental Branch.—S. C. Allen is granted a non-permanent commission as a Flying Officer.

INDIAN MEDICAL SERVICE.

Lt.-Col. L. P. Brassey to be Col.

Lt.-Col. (Bt. Col.) R. A. Needham retires.

Lts. S. S. Bhatnagar, B. Chaudhuri, H. L. Batra, A. V. O'Brien, S. T. Davies, S. M. K. Mallick, C. Mani, and E. S. S. Lucas to be Capts.

Lt. K. H. A. Gross to be Capt. (prov.).

Lt. (on prob.) Rewati Raman Bakhshi to be Capt. (prov.) (on prob.).

Lts. (T.C.) to be Capts. (T.C.).—A. S. Arora, Y. N. Lal, A. Ahmad, and K. B. Gore.

Lt. T. Das relinquishes his temp. commn.

The undermentioned appts. are made:—To be Capt. (prov.) (on. prob.): Gopal Das Malhoutra, Bantwal Panduranga Baliga, and Amar Nath Chopra.

To be Lts. (on prob.): Rewati Raman Bakhshi from I.M.S. (T.C.), Percy Vivian Bamford, Harold Duncan Ross Zscherpel, Anil Kumar Gupta, and Abani Kumar Chaudhuri.

The undermentioned officers retire: Lt.-Cols. H. G. S. Webb and J. G. G. Swan.

FLORENCE NIGHTINGALE'S CARRIAGE.—The town council of Chesterfield has presented Miss Nightingale's "Crimean carriage" to St. Thomas's Hospital. In view of her long association with the hospital this was thought to be its most appropriate home.

AN OPERATING BLOCK AT BOLTON.—Canon Elsee recently formally opened a new operating block at Bolton Infirmary, which has cost about £9000. Dr. F. R. Mallett, the president of the infirmary, described the block as the finest in the British Isles. The cost was undertaken by the 160 churches in the district, but so far only about £3000 has been obtained.

MEDICAL NEWS

University of Cambridge.

On Nov. 1st the following degrees were conferred:—

M.B. & B.Chir.—J. H. Gibbens, G. J. Gross, and W. R. F. Wood.

M.B.—H. J. Heathcote.

Royal College of Physicians of London.

At a quarterly comitia of the College, held on Oct. 30th with Sir John Rose Bradford, the President, in the chair the following candidates were admitted to the Membership of the College:—

Joges Chandra Banerjea, John Robert Blazé, Harold Ernest Brown, Alfred Bramwell Cook, Charles Clifford Davis, Percival Cholmondeley Chalmers de Silva, Doris Louise Durie, Horace Evans, Raymond Eustace Ford, Traugott Ernest Gumpert, Francis Findlay Hellier, Harold Percival Himsworth, Mohamed Ahmed Ibrahim, Louis Philippe Eugène Laurent, John Neil Leitch, Robert Alexander McCance, Owen Reginald McEwen, George Osborne Mitchell, John Henry Mulvany, Thomas Saint Martin Norris, James Vincent O'Sullivan, Trevor Kingsley Owen, James William Reid, Thomas Robson, Harold Edmund Rykert, Baldev Singh, and William Wood.

Licences to practise were conferred upon 153 candidates (including 22 women) who have passed the final examination of the Conjoint Board. The following are the names and medical schools of the successful candidates:—

E. F. Adams, Manchester; G. L. Alcock, Cambridge and St. Thomas's; R. M. Alderton, London; G. H. H. Ames, L.D.S., Univ. Coll.; M. Baillie, King's Coll.; G. Balasuriya, Ceylon and Guy's; N. B. Bapat, Bombay and Birmingham; C. O. Barnes, Cambridge and St. Bart.'s; C. R. G. Barrington, Univ. Coll.; J. H. Bartlett, Cambridge and St. Mary's; A. K. Basu, M.B., Univ. Coll.; D. S. Bateman, Oxford and St. Thomas's; J. H. Beilby, Cambridge and St. Thomas's; H. H. W. Bennett, London; J. N. Bhada, L.M.S., Univ. Coll.; Ilma B. S. Bingemann, St. Mary's; A. T. Weston, Cambridge and Guy's; K. L. Wig, M.B., Charing Cross; A. B. Williamson, Durham; H. W. Williamson, Cambridge and St. Bart.'s; C. Wright, Univ. Coll.; F. J. Wright, Cambridge and London; and C. H. Wrigley, Cambridge and St. Thomas's.

Diplomas in Public Health were conferred jointly with the Royal College of Surgeons upon the following:—

M. Ahern, M. Ata Ullah, Balkrishna, C. L. Bhola, H. P. Chaudhuri, Annie E. Connan, A. M. Critchley, F. M. M. Eyton-Jones, V. Freeman, D. N. Ghosh, K. T. Hosain, D. R. Kajuria, R. G. Keays, B. S. Khurana, J. N. Leitch, J. C. H. Mackenzie, Mary M. Mackenzie, Y. B. Mangrulkar, A. H. Morley, P. Singh, W. H. S. Wallace, and J. S. Westwater.

The Diploma in Gynæcology and Obstetrics was conferred upon Hilda M. Lazarus, Madras and Charing Cross.

Sir Thomas Horder, Dr. Comyns Berkeley, Sir William Willcox, Dr. A. G. Gibson, Dr. M. A. Cassidy, and Dr. Carey Coombs were elected councillors. Dr. Comyns Berkeley was appointed representative of the College on the Central Midwives Board. Dr. R. A. Young was re-elected a member of the Committee of Management of the Conjoint Board, and Dr. J. A. Nixon a representative on the Court of the University of Bristol.

The President announced that Prof. C. C. Okell had been appointed by the Council to be Milroy lecturer for 1932, and that the Jenks memorial scholarship for 1930 had been awarded to Frederick Basil Kiernander, until lately of Epsom College.

Society of Apothecaries of London.

At recent examinations the following candidates were successful:—

Surgery.—C. L. Ferguson, London Hosp.; H. R. Fosbery, Middlesex Hosp.; V. R. O. Lahanmi, Manchester Univ.; S. Lokecz, St. Bart.'s Hosp.; J. M. L. Love, St. Mary's Hosp.; E. H. W. Lyle, Cambridge Univ. and King's Coll. Hosp.; C. O. Parsons, Sheffield Univ. and St. Bart.'s Hosp.; L. C. H. Sykes, Leeds Univ.; and P. Wade, Liverpool Univ.

Medicine.—R. F. T. Finn, St. Bart.'s Hosp.; B. C. Ghose, Durham Univ.; C. R. Graham, Queen's Univ., Kingston, Ontario; M. Halperine, Univ. of Paris and London Hosp.; T. C. Keble, St. Mary's Hosp.; R. D. Newton, St. Bart.'s Hosp.; C. G. Nicol, St. Mary's Hosp.; G. S. Rozario, King's Coll. Hosp.; and C. P. Seeley, St. Mary's Hosp.

Forensic Medicine.—E. J. Jones, School of Medicine, Cardiff; and R. D. Newton, St. Bart.'s Hosp.

Midwifery.—H. Glynn, Charing Cross Hosp.; C. R. Graham, Queen's Univ., Kingston, Ontario; J. Irger, Univ. Coll. Hosp.; and W. A. Naidu and H. I. Newman, London Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: M. Asaad, R. F. T. Finn, B. C. Ghose, H. Glynn, C. R. Graham, M. Halperine, T. C. Keble, J. M. L. Love, H. I. Newman, R. D. Newton, C. G. Nicol, and C. P. Seeley.

Royal College of Surgeons of Edinburgh.

At the recent dental examinations of the College, out of 38 candidates entered, the following have passed the final professional examination and have been granted the diploma L.D.S. R.C.S. Edin.: R. F. K. Webster, J. S. Couper, A. W. Gregory, D. K. Cowan, B. A. Armitage, L. J. Goggins, and L. L. Whitton, and Anne M. Munro.

University of Bombay.

Dr. Abraham S. Erulkar has been elected dean of the Faculty of Medicine in the University.

Medical Society of Individual Psychology.

The next meeting will be on Nov. 13th, at 8.30 P.M., at 11, Mandos-street, W.1, when Dr. F. G. Crookshank will speak on Individual Psychology and the Bases of Medical Science.

Fellowship of Medicine and Post-Graduate Medical Association.

Arrangements for the coming week will be found in our Medical Diary. Continuing until Nov. 29th is an afternoon and evening course on Venereal Disease at the London Lock Hospital. From the 10th to the 28th the staff at the Royal Waterloo Hospital will give a course in Medicine, Surgery, and Gynæcology. From Nov. 17th to Dec. 13th a course of lectures illustrated by cases will be given at 5 P.M. at the West End Hospital for Nervous Diseases. An all-day course on Diseases of the Chest will be given at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, from Nov. 17th to 29th. Another all-day course on Diseases of the Rectum will be held at St. Mark's Hospital from Nov. 24th to 29th. Further particulars may be had from the Secretary of the Fellowship of Medicine, at 1, Wimpole-street, London, W. 1.

Prince of Wales's Hospital Dinner.

The annual dinner of the Prince of Wales's Hospital Reunion Association will be held at the Trocadero Restaurant, Piccadilly Circus, W., on Thursday, Nov. 27th, at 7.45 for 8 P.M. with Mr. W. E. Tanner in the chair. Those wishing to be present should inform Dr. Bruce Williamson, 137, Harley-street, W. 1, stating the number of guests they are bringing.

West Riding Edinburgh Graduates.

The West Riding Association of Graduates of the University of Edinburgh will hold their annual general meeting at 6.45 P.M. and dinner at 7.30 P.M., on Friday, Nov. 21st, at the Great Northern Hotel, Leeds. Sir Norman Walker is to be the guest of the evening. Any graduate requiring further information should apply to the hon. secretary, at 33, Manor Row, Bradford.

National Institute for the Deaf.

A Conference on the Higher Education of the Deaf will be held by this Institute at University College, Gower-street, London, W.C., at 2.30 P.M., on Wednesday next, Nov. 12th. Lord Charnwood will preside and the business will be to consider a report from the Committee on the Higher Education of the Deaf and decide what steps, if any, should be taken towards realising the scheme submitted.

Specialist Nurses.

The Middlesex Hospital is establishing a system of specialist nursing. In addition to the diploma upon the completion of four years' training in general nursing, nurses will be able to obtain a special certificate of having received additional training in some particular branch. The new nurses' home comprises a model ward and operating theatre in which practical instruction is given with the aid of dummy patients.

Retirement of Two Coroners.

Sir Walter Schröder, coroner for Central London, retired last week at the age of 75 after 60 years' association with coroner's work in London and district. He has held over 30,000 inquests and attended 20,000 others. On relinquishing his duties he received a presentation from the coroners' officers.—Dr. H. R. Oswald has retired from the coronership of the Western District of London, where he has served since 1919.

Contributory Schemes in Essex.

A contributory scheme for Chelmsford Hospital will come into operation on Jan. 1st next. A married man, by contributing 3*d.* per week, will be entitled, together with his wife and children up to the age of 16, to the benefits of the scheme; single men and women, with dependants, will contribute a like sum, and those without dependants 2*d.* per week.—Of the income of the Colchester General Hospital, amounting to about £25,000, the workers' committee for the borough and the contributory scheme for the country districts together provide more than £10,000.

Memorial to Sir G. S. Abram.

Lady Abram and Lieutenant R. S. Abram, R.N., recently unveiled memorial tablets at the Royal Berkshire Hospital, Reading, to the late Sir George Stewart Abram. They are placed in the new balconies for open-air treatment at the hospital which, the inscription records, were his "cherished project." Sir George was physician to the hospital from 1904 to 1928. The cost has been "defrayed by his friends and admirers."

Birmingham's Mental Patients.

Last week an extension was opened of Witton Hall, Erdington, one of the homes belonging to the city of Birmingham for the care of healthy mental cases. The extension, which has cost £12,500, provides accommodation for 98 aged men. It was stated at the opening ceremony that proper classification at other mental institutions would compel the public assistance committee to provide very considerable further accommodation.

Congress of Industrial Medicine.

The Sixth International Congress of Industrial Accidents and Diseases will be held at Geneva on August 3rd, 1931. The principal questions for discussion will be the sequelæ and final results of traumatic wounds of the spine, traumatism of blood-vessels, cutaneous affections in relation to occupation, the influence of previous health on the results of industrial accidents, illness affecting men working upon cement and artificial stones, the reaction of the organism towards the toxic substances used in industry, and fatigue. Further information may be had from the secretary of the British National Committee, Industrial Welfare Society, 51, Palace-street, Westminster, London, S.W. 1.

King's College Hospital.

The authorities of this hospital have now decided to admit a limited number of women students to the clinical course.

Southampton Contributory Scheme.

This scheme began work last year, when £9252 was collected; in less than ten months of the present year the contributions have reached £16,371. There are 764 collectors.

Extension of Worcester Infirmary.

At a town's meeting of the citizens it has been decided to raise £90,000 for extensions to Worcester General Infirmary. Although only £18,000 is in hand the first part of the scheme is to be begun at once.

Presentation.

Dr. Joseph Bradley, the oldest medical practitioner in Salford, and his wife, who recently celebrated their golden wedding, were last week presented at the Salford Town Hall with an illuminated address and a cheque by their medical friends in Salford. Dr. Bradley has rendered loyal service to Salford not only in the medical profession but in the general civil life of the city for half a century, and for more than 30 years has given devoted service to public education.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Nov. 10th.—5 P.M., UNITED SERVICES. Paper. Group Captain Martin Flack: Air-sickness and Sea-sickness.
TUESDAY.—5 P.M., THERAPEUTICS. An informal Discussion on The Uses of Mercurochrome. Opener: Dr. J. H. Burn. UROLOGY: Members of this section are specially invited to attend and take part in the Discussion. 8.30 P.M., PSYCHIATRY. Presidential address. Dr S. A. Kinnier Wilson: The Approach to the Study of Hysteria.
WEDNESDAY.—5.30 P.M., SURGERY: SUBSECTION OF PROCTOLOGY. Presidential address. Mr. Lionel E. C. Norbury: Multiple Primary Malignant Growths, with Special Reference to the Colon and Rectum. Illustrative specimens will be shown.
THURSDAY.—8.30 P.M., NEUROLOGY AND OPHTHALMOLOGY. Special Discussion on Vascular Tumours of the Brain and Spinal Cord. Openers: Dr. A. Lindau (Sweden), Mr. Treacher Collins (Ophthalmology), Sir Percy Sargent (Neurology). Followed by Dr. J. G. Greenfield, Mr. G. Jefferson, Dr. Dorothy Russell, and others. Members who wish to take part in the Discussion please communicate with Dr. C. P. Symonds, 74, Wimpole-street, London, W.
FRIDAY.—5.30 P.M., CLINICAL. (Cases at 4.30 P.M.) Dr. F. E. Saxby Willis: Aortic Aneurysm and ? Syphilis of the Lung. Dr. F. Parkes Weber and Dr. M. Scholtz: Anæmia with Splenomegaly. Simple Achlorhydric Anæmia (Dr. L. J. Witts). Mr. Harold Edwards: ? Specific Disease of the Humerus in a Girl aged 15 Years. Dr. D. W. Buxton: Thrombo-angiitis Obliterans. Mr. R. Rutherford: Hermaphroidism. Mr. Paul Bernard Roth: Fracture Dislocation of the Ankle Joint. Dr. Harold Avery: Multiple Osseous Defects. Mr. Cecil P. G. Wakeley: Congenital Short Humerus. Advanced Osteo-arthritis of the Hip-joint. Mr. Eric A. Crook: Cyst of the Neck. Other cases will be shown. Reports will be given on the following cases that have been shown at previous meetings: Mr. Cecil P. G. Wakeley: Vascular Tumour of the Brain. Dr. Hugh S. Stannus: A Case Illustrating Banti's Syndrome in Syphilis. Dr. Salisbury Sharpe: Tuberculosis of the Prostate. OPHTHALMOLOGY. No meeting.

ROYAL INSTITUTION, 21, Albemarle-street, W.
TUESDAY, Nov. 11th.—5.15 P.M., Mr. C. D. Ellis, F.R.S., Aspects of Radio-activity.
THURSDAY.—5.15 P.M., Prof. J. B. Haldane: Physiology of Water.

HARVEIAN SOCIETY OF LONDON.
THURSDAY, Nov. 13th.—8.30 P.M. (at the Town Hall, Paddington Green, W.), Two Cinematograph Films by Kodak Ltd.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, Russell-square, W.C.
FRIDAY, Nov. 14th.—5 P.M., Prof. David Burns: Some Points of Contact between Preventive Medicine and Physiology.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Nov. 10th.—8.30 P.M., Discussion on The Diagnosis and Treatment of Malignant Disease of the Chest. To be introduced by Prof. Chevalier Jackson.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.
FRIDAY, Nov. 14th.—8.45 P.M. (at the Miller General Hospital, Greenwich-road, S.E.), Dr. E. P. Cumberbatch and Dr. C. A. Robinson: Diathermy in Gynæcology.

PADDINGTON MEDICAL SOCIETY.
TUESDAY, Nov. 11th.—9 P.M. (at the Great Western Hotel, Praed-street, W.), Dr. C. M. Wilson: The Relationship of the Consultant to the General Practitioner.

BIOCHEMICAL SOCIETY.
FRIDAY, Nov. 14th.—5 P.M. (at St. Thomas's Hospital Medical School), Various communications.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.
THURSDAY, Nov. 13th.—5 P.M., Dr. L. S. T. Burrell: Indications for Treatment in Pulmonary Tuberculosis (Mitchell Lecture.)

Liverpool University.—Lecturer in Dermatology.
London Jewish Hospital, Stepney Green, E.—Res. M.O., and Cas. O. Each at rate of £150. Jun. Res. M.O. At rate of £100. Also Clinical Assts.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.
Manchester, Ancoats Hospital.—Orthop. H.S. At rate of £100.
Margate Borough.—M.O.H., &c. £900.
Metropolitan Hospital, Kingsland-road, E.—Surg. to Ear, Nose, and Throat Dept.
Middlesbrough Education Committee.—Asst. School M.O. £500.
Newcastle General Hospital.—Sen. Res. M.O. £300. Also H.P. and H.S. Each at rate of £100.
Newcastle-upon-Tyne Hospital for Sick Children.—Res. H.P. At rate of £95. Res. Sen. H.S. Also Jun. H.S. Each at rate of £100.
Northampton County Mental Hospital, Berrywood.—Jun. Asst. M.O. £350.
Northamptonshire County Council Education Committee.—Asst. School M.O. £500.
Northwood, Middlesex, Mount Vernon Hospital.—Res. M.O. £300.
Oswestry, Shropshire Orthopædic Hospital and Agnes Hunt Surgical Home.—Two H.S.'s. Each at rate of £200.
Plymouth Central Hospital.—H.S. £120.
Preston, Biddulph Grange Orthopædic Hospital.—Sen. H.S. At rate of £250.
Preston County Borough.—Asst. School M.O. £600.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, N. Kensington.—H.P. At rate of £100. Also Hon. Asst. Anæsthetist and Hon. Assist. Dental Surgeon.
Queen's Hospital for Children, Hackney-road, E.—H.P. At rate of £100.
Richmond, Surrey, &c., Joint Isolation Hospital Committee, Hospital, Mogden.—Res. M.O. £400.
Royal Free Hospital, Gray's Inn-road, W.C.—Surg. Reg. £200. Res. H.S. to Ear, Nose, and Throat Dept., Res. Cas. O. £150. Res. Anæsthetist to Gynæcological, &c., Unit. £150. Half-time Gynæcological Reg., Med. Reg., and District Obstetric Asst. Each £100. Also Res. H.S.'s, H.P.'s, Asst. Anæsthetist, &c.
Royal Northern Hospital, Holloway, N.—Two Surgeons.
Ryde, Royal Isle of Wight County Hospital.—Res. H.S. At rate of £180.
St. Mary's Hospital, Inst. of Path. and Research, Paddington, W.—Research Studentship. £200.
Sheffield Royal Hospital.—Ophth. H.S. At rate of £80.
Shoreditch Metropolitan Borough.—Tuberculosis Officer. £750.
Walsall General Hospital.—Cas. H.S. At rate of £120.
West London Hospital, Hammersmith-road, W.—Hon. Reg. to Throat, Nose, and Ear Department.
Westminster Hospital Annexe, 66, Fitzjohn's-avenue, Hampstead. Jun. H.S. At rate of £250.
West Riding of Yorkshire C.C.—Asst. Bacteriologist. £500.
Wigan Royal Infirmary.—H.S. At rate of £150.
Willesden Urban District Council.—Public Vaccinator.
Winchester, Royal Hampshire County Hospital.—H.S. At rate of £150.
Wolverhampton Royal Hospital.—H.S. At rate of £150.
Woolwich and District War Memorial Hospital, Shooters-hill, S.E.—H.S. £100.
Yelverton, Udal Torre Sanatorium.—Res. M.O. £450.
York Dispensary.—Res. M.O. £150.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Market Drayton (Salop), Hoyland Nether (Yorkshire), Cheadle (Staffordshire), and at Church Gresley (Derbyshire).

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Districts of the Beverley, Bridlington, Goole, Great Driffield, Kingston-upon-Hull, Pocklington, and Selby County Courts (Circuit No. 16). Applications should reach the Private Secretary, Home Office, Whitehall, S.W., not later than Nov. 22nd.

Births, Marriages, and Deaths

BIRTHS.

ADAMSON.—On Oct. 27th, at Hendon, the wife of A. Fairgrieve Adamson, M.D., of a son.
CAPELL.—On Nov. 2nd, at Cricklewood-lane, N.W., the wife of L. F. Capell, M.B., Ch.B. Edin., of a daughter.
COOKE.—On Oct. 25th, at Chelwood Gate, Sussex, the wife of Dr. Alec Cooke, of a daughter.
VERDON.—On Oct. 20th, at Wellington, S. India, the wife of Major Philip Verdon, I.M.S., of a son.

MARRIAGES.

ANSON—ATTWELL.—On Nov. 6th, at St. Lawrence Church, Ramsgate, Charles Everett Heyworth Anson, M.B., B.S. Lond., to Mabel Winifred, youngest daughter of Mr. and Mrs. J. J. Attwell, of Ramsgate, Kent.
GRAY—SLOAN.—On Oct. 29th, at St. Giles' Cathedral, Edinburgh, James Douglas Allan Gray, M.B., Ch.B., B.Sc., M.R.C.P.E., D.P.H., to Agnes Dorothy Sloan, M.B., Ch.B.
HARRISON—DAVIS.—On Nov. 1st, at Beckenham, Kent, Dr. W. R. E. Harrison to Dr. Mirabel Grace Davis.

DEATHS.

BARRON.—On Oct. 30th, at Lynorne, Shalford, Surrey, Willie Netterville Barron, C.M.G., M.V.O., M.R.C.S., L.R.C.P.
MACALISTER.—On Nov. 2nd, at Guy's Hospital, after a long illness, George Hugh Macalister, M.D., M.R.C.P., late Principal of King Edward VII. College of Medicine, Singapore, aged 51.
MULVANY.—On Oct. 27th, at Hotel Brice, Nice, Edward Mulvany, Surgeon Leiutenant-Colonel, Indian Medical Service, aged 80.
ROBERTS.—On Oct. 27th, at Eastbourne, Charles Gordon Roberts, M.A., M.B., D.Sc., of Banbury, Wash-lane, Clacton-on-Sea, formerly of Halstead, aged 66.
WATTS.—On Nov. 2nd, accidentally drowned, Cecil Francis Watts, M.A., B.Chir., M.R.C.S., L.R.C.P., of St. Bartholomew's Hospital, aged 28.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

SCOTLAND'S CONTRIBUTION TO MODERN MEDICINE.

Abstract of a Broadcast Talk by

SIR LESLIE MACKENZIE, M.D., LL.D.,
LATE MEDICAL MEMBER OF THE SCOTTISH BOARD OF HEALTH.

SCOTLAND, with a long and distinctive history, has retained, within the Union of the Kingdom, its own primary institutions, such as the Law Courts and the Scottish Laws, its system of County and Burgh administration, its central Government Departments—the Department of Health, the Education Department, the Department of Agriculture, the Scottish Registrar-General, and several others. In many ways the administrative bodies, both central and local, differ from those of the other Kingdom. But the main fact is that those bodies are under the general control of the Secretary of State for Scotland, and are worked as independent bodies directly responsible to Parliament through a Secretary of State. Many sections, therefore, of modern medicine take a special colour from the fact that they have been developed in the Northern Kingdom. I shall try to indicate broadly what Scotland has done and is doing to promote the development of modern medicine, using only such matter as appears to be predominately, if not perhaps exclusively, Scottish.

[Sir Leslie here recalled the individual contributions of great Scotsmen like Simpson, Macewen, Ogston, Manson, and Mackenzie to progressive learning, and continued :—]

THE SCOTTISH MEDICAL OUTPUT.

The Medical Register as at date Jan. 1st, 1930, contained 54,870 names of registered medical practitioners. Of this total 26,314, that is about 48 per cent., entered by the English Register; 17,198, that is 32 per cent., by the Scottish Register. This shows, in absolute numbers, a substantial preponderance for England. But if we ask what is the proportion in each country to the total population of each country, the facts reveal a striking difference. England, with a population of some 36,000,000 supports medical schools or examining bodies that produce 26,314 graduates, that is about 0·73 per 1000 of the population. Scotland, with a population of about 5,000,000 supports medical schools or examining bodies that produce 17,198 graduates, that is about 3·4 per 1000 of the population. It is true that the number of graduates has no very direct relation to the total population; but the fact that Scotland is responsible for a number that, in proportion to population, is about five times as great as England's, seems to indicate that, at least proportionally, Scotland plays a greater part in the education of the profession than England does. I am not prepared to discuss the reasons; but it is certain that Scotland does provide a very large part of the medical profession for the Empire and the countries associated with it. This may fairly be interpreted as a testimony to the value of Scotland's teaching contribution to modern medicine. Her great schools are highly equipped in every branch of medical teaching and inquiry. They attract students from the Empire and from many countries outside. The large numbers of Scottish graduates that practise at home or go abroad keep up a constant stream of new students. No schools could succeed in doing this for so long a period if they did not stand on a high plane of equipment and efficiency. I may add, as a modification, that many students may train in England and Ireland and graduate in Scotland, just as many Scottish students may train in Scotland and graduate in England. But, with every modification, the facts are somewhat striking.

MEDICAL RESEARCH.

The researches carried out by Scottish investigators in Scotland constitute an important proportion of the Medical Research Council's output. The Council has established a large number of committees, each in charge of a group of medical problems. These committees include representatives from all interested schools in the United Kingdom, and Scotland has its share. Apart, however, from the Medical Research Council, other research work is carried on for Scottish problems as such. Certain preliminary investigations have been made of rickets and other subjects are under active consideration. Here emerges a somewhat important principle. Should research be dissociated from teaching? In some countries research and teaching are wholly separate and, to a certain extent, this is true in Scotland. But in our Universities the custom has been for the teaching professors to continue researches in their own subjects and also to teach. Speaking generally, all the medical professors and their assistants engage steadily in the investigation of the current problems. One of them has said to me that the maintenance of research in his department gives greater interest and vitality to his teaching and he engages in research because he wishes himself to keep abreast of medical discovery and because it enables him to teach better. This aim tends to keep research practical and to keep practical teaching vitally scientific. But there is room for development here as in other aspects of medicine.

Some years ago an institute was built at Bucksburn, near Aberdeen, for the study of animal nutrition—the Rowett Institute, so named after the generous founder. Two years ago an experiment on a large scale was conducted on the dietetic value of milk and milk products. Groups of children of given ages in elementary schools in Scotland were fed with milk over a period long enough to yield stable results. The effects of whole milk, separate (or skim) milk, and an equivalent amount of biscuit, all as a supplement to the ordinary diet, were worked out statistically. It was found that growth in height and in weight was materially stimulated by the extra ration of milk, but not by the biscuit. The experiment was repeated in a second year and the results were confirmed. At the present moment an experiment of the same kind is proceeding. It involves 20,000 school-children. Like the previous experiment, this is under the general direction of Dr. John Boyd Orr, Director of the Rowett Institute. The details have been arranged through the Department for Scotland. The finance has been provided by the Empire Marketing Board. So far as I am aware, these large-scale experiments in the feeding of school-children in school conditions are exclusively Scottish. It may be added that, in the final report of the first experiment, the diet of some hundreds of families will be found analysed in detail.

SCHOOL HEALTH ADMINISTRATION.

These school researches lead, naturally, to the problems of School Health Administration in Scotland. In 1903 the Royal Commission on Physical Training (Scotland) issued its report, and included two special investigations of random samples of Scottish school-children. The revelations made in these special reports at once excited the interest of Parliament. The Commission definitely recommended systematic medical examination of school-children. In the same year an Inter-Departmental Committee was appointed to report on the larger question of physical deterioration. This committee confirmed the Scottish Commission's report. Later a Scottish Education Bill was prepared and included a clause on medical inspection; later still another bill was prepared; but it was not till 1907 that England obtained powers to examine; and in 1908 Scotland was empowered to require the School Authorities to make a medical

examination of all school-children and to treat necessitous children. A system of School Health Administration, including school clinics, was rapidly organised under these powers. The results to-day are impressive. In the report by the Scottish Board of Health for the year 1928 it is stated that of the 325,440 children attending the 3389 State-aided schools in Scotland some 386,194 were medically examined and treatment was provided for those needing it. The system, starting from almost nothing in 1908, now is carried out by a large number of part-time and whole-time medical officers and school nurses. In this section of work Scotland may fairly claim to have made an independent start. The chief impulse, undoubtedly, came from two members of the Royal Commission—namely, the late Sir Henry Craik, M.P., who was at that date Secretary for the Scottish Education Department, and the late Sir Alexander Ogston, who was the only medical member. A unanimous report resulted.

[After detailing the pioneer work done in Scotland in the control and treatment of tuberculosis the lecturer continued :—]

HOUSING.

The Royal Commission on Scottish Housing was set up in 1912 and issued its report in 1917. Members of the Commission visited every county of the mainland, and also the main groups of islands ; the Orkneys, the Shetlands, and the Inner and Outer Hebrides. The chief recommendation was that an explicit obligation should be placed on the local health authorities to survey the housing of their districts, and themselves to build houses where these were not otherwise provided in adequate numbers. This was the one really new proposal. It was, in principle, a departure of the first magnitude. In 1919 it was embodied in an English Statute as well as in a separate Scottish Statute. Several acts have been passed since then, but the obligation on the local authorities remains. The Commission recommended that some 235,000 houses were needed for Scotland. At date, if we include all houses subsidised by the State, the number actually built since 1919 or in process of building is now over 122,000. There is still a long road to travel, but in this new departure Scotland took a lead of her own. A generation or more must elapse before the effects on the general health can be fairly tested statistically, but all authorities are agreed that the good housing of the people is an essential to the general promotion of health, which is another name for preventive medicine.

HIGHLANDS AND ISLANDS MEDICAL SERVICE.

A special Act of Parliament has sanctioned an annual grant for the provision of an adequate medical and nursing service for the Highlands and Islands. The system stands alone of its kind in Great Britain. It has been explicitly recognised as the inspiration of the Frontier Nursing Service in the Appalachian Mountains of Kentucky, and full information has, on request, been furnished also to the authorities of Newfoundland, the Province of Ontario, and areas in South Africa. Over £600,000 were expended in the first 14 years in subsidising doctors and nurses, in the provision of doctors' and nurses' houses, subsidising hospitals, appointing of resident operating surgeons in selected centres, and other elements of a medical service.

TOXIC EFFECTS OF ETHYLENE OXIDE.

THE results of an investigation of the response of guinea-pigs to ethylene oxide made by C. P. Waite, F. A. Patty, and W. P. Yant, of Pittsburgh, have been published by the United States Public Health Service.[1] The object of the work was to estimate the hazards involved in exposure to certain chemical products which have recently reached, or promise to reach, important domestic and industrial use, and of which ethylene oxide is an example. The uses to which it is at present put are as intermediate in the synthesis of compounds such as methyl, ethyl, and butyl cellosolve, and as a fumigant, either alone or mixed with carbon dioxide, in which capacity it acts by stimulating the respiration of insects. The authors found that guinea-pigs exposed to the vapour showed, first, signs of nasal irritation, as indicated by scratching at the nose, ocular irritation with lacrymation and squinting, and later blood-tinged, frothy serous exudate from the nostrils, unsteadiness and staggering ; finally, the animals were unable to stand, respiration increased in rate and amplitude, until a state of gasping dyspnœa was reached accompanied by the use of accessory muscles and raising of the head ; death followed. Guinea-pigs exposed to 1·4 per cent. concentration fell and lay on their sides in 50 to 107 minutes, while exposure to 0·7 per cent. caused all animals to fall in 150 minutes. The first effect of higher concentrations—8·5, 6·4, and 0·7 per cent.—was to increase the depth and amplitude and to slow the rate of respiration in 13, 17, and 35 minutes respectively. With exposure to smaller concentrations, such as 0·13 and 0·06 per cent., irritation of the eye and nose were the principal symptoms, while with 0·025 per cent. no distinct symptoms were observed. Pathological examination of the animals which died as a result of exposure, either within a few hours or after several days, showed the presence of a marked irritation of the respiratory system, with the super-imposition, in the animals which died late, of lobar or lobular pneumonia and parenchymatous changes in the kidney. The observers conclude that in the case of guinea-pigs 0·3 to 0·6 per cent. for 30 to 60 minutes is dangerous to life, 0·3 per cent. is the maximum for 60 minutes without serious disturbance, and 0·025 per cent. is the maximum allowable concentration for several hours without serious disturbance ; 5 to 10 per cent. causes death within a few minutes. In toxicity ethylene oxide is less harmful than hydrogen chloride and sulphur dioxide, more harmful than chloroform and carbon tetrachloride, and similar to ammonia. It has not enough smell to give warning of harmful concentrations, but the distinct irritation of the nose to which it gives rise, even in comparatively safe concentrations, should be taken as warning of a dangerous atmosphere.

THE CLINICIAN AS PATHOLOGIST.

IN the course of a presidential address delivered to the Manchester Pathological Society on Oct. 8th, Dr. E. Bosdin Leech discussed the development of pathology as a separate science and regretted the specialisation which prevented physicians and surgeons from obtaining an early training in the post-mortem room. Last century, he said, the study and teaching of pathology had diverged along two different lines. In some places its teaching remained in the hands of physicians and surgeons of observing habit who conducted their own post-mortem examinations. Their juniors, who might do the mechanical part of the work and for the time being devote themselves entirely to pathology, were simply laying a scientific foundation for their diagnostic and therapeutic work in the wards and outside. In other places it fell into the hands of specialists, men who were to devote their whole lives to pathology and had no intention of undertaking treatment. Deeper knowledge and the increase of specialties inside pathology itself had now made it necessary for pathology to be carried on by specialists, but Dr. Leech urged that in the pathological departments of our big hospitals some attempt should be made to attract the young physician and the young surgeon to pass part of his waiting period in the post-mortem room. It would be for the good of medicine. Sir Humphry Rolleston had said that no physician has ever recovered from having omitted to serve a long practical apprenticeship in the post-mortem room. Dr. Leech realised that the budding physician and surgeon could not specialise in all the modern branches of pathology, but he must learn

some good old-fashioned morbid anatomy. In England and to a lesser extent in France pathology had in general been taught by the physicians and surgeons. No better example of this type of teaching could be chosen than that of Guy's Hospital. There a series of brilliant men, Bright, Addison, Hodgkin, Wilks, showed what could be done by practising physicians, and the surgeons were in no degree behind them. The specialist type of teaching throve in Germany and Austria; notable examples of great teachers were Virchow, Koch, and Rokitansky. Dr. Leech, reviewing the developments in the middle of the last century, concluded that though the specialist work brought out a greater number of brilliant discoveries, the retention of post-mortem work in the hands of the clinicians produced the better practitioners.

A MASSAGE DIRECTORY.

WE have received a directory of the members of the Chartered Society of Massage and Medical Gymnastics who are in private practice. They have formed a group known as the Private Practitioners' Association to safeguard their interests and have issued a list in order that the medical man or woman may see where to find a member of the C.S.M.M.G., what his/her qualifications are, and what work he/she is prepared to undertake. The directory is intended only for doctors, as members of the Association have voluntarily adopted an ethical code which pledges them to work only under the direction of a registered medical practitioner. As this pledge prevents them from accepting work which might come to them directly, the Association claims with some justice the support of the doctor in utilising the services of its members. The directory, which is on a county basis, gives postal and telephone address as well as the kind of treatments which the member will undertake from massage, medical electricity, diathermy, radiography, colonic lavage, down to foam baths, steam baths and Bergonié treatment. Our only criticism is that the arrangement under counties makes it difficult to find at a glance whether a member of the Association is available in such and such a locality. In another edition we would suggest a further index of towns. A copy will be sent post free to any medical practitioner on application to the Secretary, P.P.A., Hygeia, Falmouth, Cornwall.

SCIENCE DISCIPLINE.

Sir David Prain, I.M.S., F.R.S., chose this subject for the second annual Alexander Pedler Lecture (founded by the British Science Guild) which he gave on Oct. 22nd in the University of Liverpool.

Huxley, he said, held that in an ideal university a man should be able to obtain instruction in all forms of knowledge, and discipline in the use of all methods by which knowledge might be obtained. Science no longer connoted all knowledge, but meant more particularly "natural knowledge." Science discipline, therefore, implied cultural exercise of every method by which natural knowledge could be obtained, as contrasted with science training, which implied technical exercise in any method by which natural knowledge might be employed. The sole object of science training was to make an adequate number of scholars, already disciplined in the requisite natural knowledge, competent to give the general community effective, scientific help. The purpose of discipline was two-fold: on the one hand to furnish those who wished to serve the community scientifically with the kind of natural knowledge that would enable them to profit by training for technical efficiency; and on the other hand, to render all scholars in any ideal university competent to appreciate the scientific help afforded the community by those specially trained to give it.

It needed the lesson of the Great War to convince our legislators of the truth that "what people call applied science is nothing but the application of pure science to particular problems," and an Association for the advancement of science had to reach its hundredth year before it found a president courageous enough to say that between pure and applied science there was no real distinction. There was room for hope that academic opinion might now cease to consider second-rate advancement more important than first-rate application of natural knowledge. General cultural science discipline was the proper business of faculties of arts, not of science. A special scientific discipline, preparatory to technical training, also had its place within the universities, and demanded recognition and special organisation. Sound practical instruction in the elementary facts and broad principles of biology should form part of the arts curriculum. The absence of any serious attempt on the part of those entrusted with university organisation to devote themselves to the "patient study of scientific teaching" in their faculties of arts, was directly responsible for much of the justifiable disquietude felt by both teachers and scholars of natural knowledge to-day. It was of less consequence for teachers of science to fail to distinguish between the functions of a technical and a cultural faculty, than to fail to make their universities understand the difference in method between the science discipline for culture and the science discipline that prepared for training.

SMALL-POX AND THE PUBLIC.

To the Editor of THE LANCET.

SIR,—The modern attitude towards small-pox is here exemplified. A school-teacher in Bethnal Green had nine children away one recent Monday. By Friday eight were reported to be small-pox victims, but it was not until the following Tuesday that the father of the ninth thus excused the absence of his daughter. I give his exact words:

"Madame and Miss, excuse Amelia being away but she has been under the doctor who could not diagnose her. First she was off her food, very quiet and lifeless, then she was irritable and cross. Her mother thought she was about to become a female, but it was *only* the small-pox after all."

Amelia returned to school very pock-marked and, incidentally, also a "female"!

I am, Sir, yours faithfully,

C. BERKELEY WAY.

BRITISH SPA FEDERATION.

THE manager of Droitwich Spa informs us that although Droitwich has not joined the official scheme for treating insured persons (described on p. 975 of our last issue), it nevertheless belongs to the British Spa Federation, and receives a number of patients belonging to this category from various sources.

"THE THREE-CARD TRICK."

REFERRING to a note under this title in our last issue (p. 1000), Dr. C. W. Hutt points out that Holborn was the first authority to undertake anti-diphtheria immunisation at a maternity and child welfare centre. This work was begun so long ago as 1922.

CONTRIBUTORY PENSIONS LEGISLATION.

A SHORT summary of contributory pensions legislation recently published [1] may help those who wish to verify the claims of prospective pensioners. There is an occasional trace of preoccupation with the Scottish application of the law; thus the Contributory Pensions (References) Regulations (Scotland) of 1925 are specifically mentioned, but not the corresponding English regulations of 1928. The handbook is, however, a useful guide to both the English and Scottish provisions of the principal Act of 1925 and the copious amendments made last year. One such amendment, it may be remembered, lifted the disqualification imposed on inmates of poor-law institutions in a case where a patient has entered the institution merely to obtain medical or surgical treatment.

ADDRESSES AND ORIGINAL ARTICLES

PAROXYSMAL TACHYCARDIA.

The Bradshaw Lecture delivered before the Royal College of Physicians of London on Nov. 4th, 1930,

By W. E. Hume, C.M.G., M.A. Durh., M.D. Camb.,
FELLOW OF THE COLLEGE; SENIOR HONORARY PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE; LECTURER IN SYSTEMATIC MEDICINE IN THE UNIVERSITY OF DURHAM.

In selecting paroxysmal tachycardia as my subject I have chosen a common and dramatic syndrome which has been well recognised in its chief clinical manifestations for half a century, and in which renewed interest was aroused when the electrocardiograph was introduced into clinical work about 20 years ago. This renewed interest has resulted in a clearer conception of the mechanism of a paroxysmal attack, though the prime factors of causation are even now completely obscure. The literature has become voluminous, and for the most part consists in the electrocardiographic description of isolated cases or small groups of cases, and a pause to take stock of the accumulated material is my excuse for speaking on the subject, although in a single lecture, and with a personal experience limited to a series of 50 cases, my review must be somewhat fragmentary.

In this country the credit for the first accurate description of an attack of paroxysmal tachycardia is assigned to Richard Payne Cotton,[12] physician to the Brompton Hospital for Consumption. His paper, entitled Notes and Observations upon a Case of Unusually Rapid Action of the Heart (232 per minute), appeared in the *British Medical Journal* in 1867. The patient, a tailor, aged 42, was under Cotton's observation for three years, and in one of the attacks Dr. J. Burdon Sanderson took a sphygmogram which counted the pulsations at exactly 220 per minute. The attacks of rapid heart action started and ended with great suddenness, and in Cotton's words "the action of the heart becoming suddenly in every respect natural and the pulse 80 in the minute." The publication of this case was immediately followed by the description of other similar cases by James Edmonds and by Sir Thomas Watson. On June 15th, 1867, Watson described a case in a middle-aged man "whose waggings of the heart were counted with the stethoscope at the rate of 216." The pulsations dropped suddenly to 72 when the attack ended, with the patient's exclamation, "There, I feel that I am all right again." In the fourth attack the patient died. There quickly followed reports of similar cases by Dr. Brown of Rochester, Dr. Bowles of Folkestone, and Dr. Broadbent, who described a typical case in a woman of 66 in St. Mary's Hospital. These accounts make it clear that their authors recognised the clinical syndrome which we now designate paroxysmal tachycardia. In 1882 Probsting[32] described three cases which had come under his own observation, and reviewed reports of similar cases from the literature. The first complete account of the condition was given by Bouveret[7] in 1889, and he named the disease *tachycardie paroxystique essentielle*. Little of clinical moment has been added to his exhaustive account, and on the Continent the syndrome is still often referred to as Bouveret's disease. In 1897 Herringham[32] reviewed 53 cases in the *Edinburgh Medical Journal*, together with an account of a typical example in a girl of 11 years under his care. At that time there could be no conception of the cardiac mechanism during the attacks of paroxysmal tachycardia. The teaching of James Mackenzie and the use of his ink polygraph stimulated renewed research in all forms of cardiac arhythmia, including the tachycardias, and an analysis of the cardiac mechanism was attempted. A more accurate analysis became possible with the advent of the electrocardiograph into clinical work, and the experimental and clinical researches of Engelmann, Lewis, and others eventually placed tachycardias on a physiological basis.

Electrocardiographic and experimental research has suggested that paroxysms of tachycardia may be generated at different levels in the heart—auricles, ventricles, and junctional tissues—and clearly defined types are recognised.

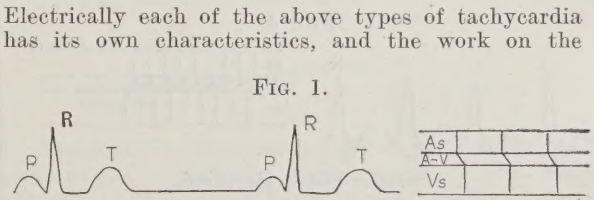
Types of Tachycardia.

There appear to be three rhythmic centres in the heart, each capable of generating rhythmic impulses. (1) The normal pacemaker of the heart lies in the sino-auricular node situated in the sulcus terminalis of the right auricle, dominating the other centres and sending out rhythmic impulses at the rate of 70–80 per minute. (2) A second centre lies in the auriculo-ventricular node (Tawara) and main bundle (His) of junctional tissues capable of generating impulses at a somewhat slower rate. (3) A ventricular centre which generates impulses at the rate of 30–40 beats per minute when the two higher centres are cut off from it or are in abeyance. The centre with the higher rate of impulse formation will always impose its dominance over the other centres, and though the above rates represent the natural speed of impulse formation, each centre is capable of generating impulses at an enormously higher rate. Under certain circumstances each centre may be so excitable that it becomes capable of sending out impulses at a regular and excessive speed which will then dominate the situation. This is the essence of paroxysmal tachycardia, and as each centre is capable of becoming the dominant pacemaker we can classify the tachycardias as follows:—

(1) Auricular:
  (*a*) Regular auricular tachycardia.
  (*b*) Auricular flutter.
  (*c*) Paroxysmal attacks of auricular fibrillation.
(2) Auriculo-ventricular (nodal):
  (*a*) Superior nodal.
  (*b*) Inferior nodal.
  (*c*) Nodal.
(3) Ventricular.

Electrically each of the above types of tachycardia has its own characteristics, and the work on the subject of paroxysmal tachycardia during the last 20 years has been chiefly the electrocardiographic study of individual cases. The result has been to show that the electrocardiographic record during an attack of paroxysmal tachycardia will usually demonstrate the level in the heart at which the abnormal rhythm is being generated (Fig. 1).

FIG. 1.

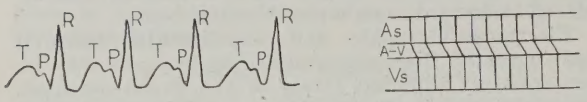


Normal.

AURICULAR TACHYCARDIA.

If the tachycardia is generated in the neighbourhood of the sino-auricular node the auricular electrical complex will have a normal appearance and P will be upright. The impulse will pass to the ventricles by the normal paths and the time of passage (P–R interval) will approximate the normal. The R wave of the ventricular complex will be sharp and characteristic of the supraventricular type (Fig. 2). If the auricular speed is very excessive—e.g., 300—the ventricles may be only able to respond to a certain

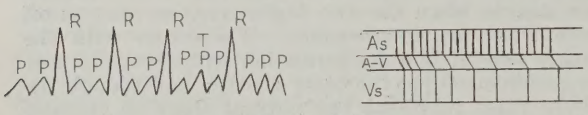
FIG. 2.



Auricular tachycardia.

proportion of the auricular impulses, and this type constitutes auricular flutter. In regular auricular tachycardia the auricular and ventricular rates are the same and vary from 140–250, and remain fairly constant in individual cases. Compression of the vagus in the neck is frequently efficacious in arresting an attack. On the other hand, in auricular flutter vagal compression may slow the ventricular speed temporarily, but this procedure has never been known to arrest an attack (Fig. 3).

FIG. 3.



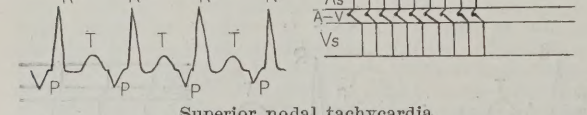
Auricular flutter.

NODAL TACHYCARDIA.

Nodal tachycardia, first described by Hering and Rihl and elaborated by Lewis,[50] with its three subdivisions, is the most common mechanism in regular paroxysmal tachycardia; the subdivision is not solely theoretical, because the varying relationship of P to R in electrocardiograms makes it apparent that the excitable centre may lie in different levels of the auriculo-ventricular node and bundle (junctional tissues).

(*a*) *Superior nodal.*—Electrically, this type is characterised by an inverted P which appears immediately anterior to R, which is sharp and of the supraventricular type. The electrocardiogram

FIG. 4.

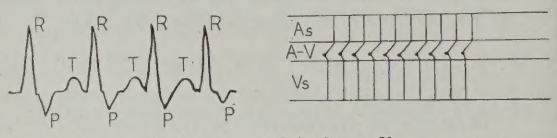


Superior nodal tachycardia.

suggests that the excitable centre lies in the upper part of the junctional tissues, and the wave of excitation, spreading towards auricles and ventricles, excites the auricles first (Fig. 4).

(*b*) *Inferior nodal.*—Conversely, P may appear immediately after R and usually notches the downstroke of R, which in its general contour is of the supraventricular type. In the inferior nodal type the electrocardiogram suggests that the excitable centre lies in the lower part of the junctional tissues and the wave of excitation, spreading towards auricles and ventricles, excites the ventricles first (Fig. 5).

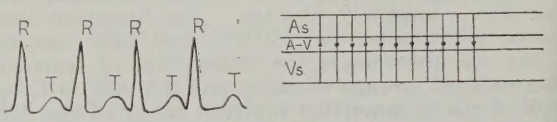
FIG. 5.



Inferior nodal tachycardia.

(*c*) *Nodal.*—If the excitable centre lies midway between auricles and ventricles and the wave of excitation passes simultaneously upwards and downwards, there will be simultaneous contraction of auricles and ventricles, with the result that P and R will coincide. In this type there is a single biphasic deflection with the characteristics of a supraventricular R (Fig. 6).

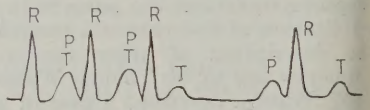
FIG. 6.



Nodal tachycardia.

Before mentioning the last variety (ventricular) it must be admitted that the classification of some electrocardiograms, characterised by a sharp biphasic R and obviously supraventricular, present difficulties in interpretation. When P falls before R in the superior nodal variety it is usually clearly defined and unmistakable. There is not, however, the same certainty in the recognition of P when it falls after R, and notches on the downward deflection of R might be variously interpreted by different observers. Similarly, when there is no evidence of P apart from R and T deflections, there is no certainty that P is buried in R—i.e., truly nodal; P may lie in the previous T denoting an auricular tachycardia. Frequently a study of the deflections at the beginning or end of a paroxysm may give the clue to the interpretation of the electrocardiogram. For instance, the form of T of the last beat of the paroxysm will show whether P has been superimposed upon it during the paroxysm (Fig. 7).

FIG. 7.



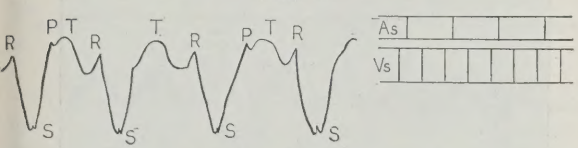
Auricular tachycardia?

However, both in those examples where P is separate and distinct and in those in which the position of P may be in doubt the R deflection is essentially of the supraventricular type and all might be classified as "supraventricular tachycardias." There seems to be evidence that the majority of electrocardiograms from cases of regular paroxysmal tachycardia present the features of a supraventricular type, and in the present state of our knowledge the more subtle subdivisions are of more academic than practical interest. For instance, there is no clinical distinction to be recognised between auricular, superior, and inferior nodal and nodal types, and no deductions can be drawn as to prognosis and treatment between a paroxysmal tachycardia of obvious auricular origin and another of obvious nodal origin.

VENTRICULAR TACHYCARDIAS.

It is otherwise, however, in the case of the last variety—ventricular tachycardia. Since Lewis, in 1909, published an electrocardiogram of ventricular tachycardia many electrocardiograms have been published which purport to show that the paroxysm has arisen in one or other ventricle. In this type the ventricular complexes have the characteristics of extrasystoles from right or left ventricle—namely, broad R and S deflections continued into a large broad T. Independent auricular deflections P can sometimes be identified amongst the ventricular deflections at a slower rate than that of the ventricles (Fig. 8).

FIG. 8.



Ventricular tachycardia.

In the interparoxysmal normal periods premature ventricular beats are apt to occur, with complexes similar to those constituting the paroxysm. Frequently it can be shown that the onset and end of the paroxysm bear the same relation to the slow rate as do the premature extrasystoles to the normal beats. There is also often a slight irregularity in the paroxysmal rate. This type of tachycardia is more frequently associated with the severer forms of heart disease and more especially with thrombosis of the coronary arteries. In 65 cases collected by Strauss[77] there was clear evidence of heart disease in 53, including 12 cases of coronary thrombosis.

Many of the recorded cases of ventricular tachycardia have had large and continued doses of digitalis, and it has been suggested that ventricular tachycardia is a toxic manifestation of digitalis in the presence of organic heart disease.

Though rare, apart from its association with gross organic heart disease, ventricular tachycardia has been described in the young and in those without any obvious heart disease, but these exceptions are scanty.[47 73] As in the case of some electrocardiograms indicative of supraventricular tachycardia there may be some uncertainty in the interpretation of apparent ventricular electrocardiograms. Certain curious electrocardiograms show bidirectional alternation of ventricular complexes[61 72] suggesting that foci in both ventricles alternately send out rhythmic impulses. These occurred in 18 out of 64 cases quoted by Strauss.[77] This appearance, however, may be otherwise explained, by presuming that the right and left branches of the bundle of His are alternately refractory and that supraventricular impulses travel alternately down one or other branch. Whatever the explanation for the bizarre appearances this type of electrocardiogram also occurs in the subjects of gross organic heart disease.

In spite of the limitations of electrocardiographic analysis the large majority of electrocardiograms from cases of regular paroxysmal tachycardia can be placed in the categories of either supraventricular or ventricular types, and we must now consider their relative frequency and the clinical facts and associations common to both varieties or peculiar to each type.

Though it is the rule that the type of paroxysm always remains constant to the individual patient there are examples of mixed types. For instance, Crawford[13] has described attacks in a medical student, aged 25 years, where during the attack the exciting centre seemed to shift from the sino-auricular node, with a rate of 181, to the auriculo-ventricular node, with a rate of 175. Barker[3] has described a case of auricular paroxysmal tachycardia which was interrupted by an attack of ventricular tachycardia; and other combinations have been described.[17 33]

During an attack of supraventricular tachycardia partial heart-block or a bundle branch block may become evident in the electrocardiogram and upset a previously regular rhythm.

In spite of these and similar irregularities the type usually remains constant to the individual, and in the supraventricular varieties the same type of attack is continued year after year. I have electrocardiograms of some patients taken over 15 years, and the records from year to year are essentially identical. In a single lecture some limitation must be placed upon the range of tachycardias to be surveyed, and I propose to deal chiefly with those regular supraventricular tachycardias which are repeated in patients year after year. Paroxysms of auricular fibrillation and auricular flutter will only be mentioned in as far as they confuse diagnosis or differ in treatment.

Paroxysmal and permanent auricular flutter was fully described by Parkinson and Bedford[62] in 1927, and both have considerable affinities with auricular fibrillation, in itself a very large subject.

INCIDENCE OF THE TYPES.

From the inherent nature of the syndrome and its irregular appearance it is only possible to obtain electrocardiographic records in a small proportion of our cases of regular paroxysmal tachycardia, and I have electrocardiographic records of 24 patients, though I have full notes of 50 cases, most of whom I have seen in attacks, and I have encountered other undoubted examples of which I have only a recollection and nothing in writing. Table I. shows the incidence in the various groups, and it is apparent that the largest incidence falls in the supraventricular type.

* 1926 collected.

Supraventricular .. .. .. 198 = 78·3 per cent.
Ventricular .. .. .. 55 = 21·7 „ „

The figure 55 representing the ventricular type of paroxysms is probably excessive and requires comment. It includes examples of short runs of ventricular tachycardia which have been described as salvoes of extrasystoles—in one case a run of 8 beats and in another a run of 13 beats.[69] These have been found on systematic electrocardiographic examination of the heart in patients suffering from gross organic heart disease. In some instances again the ventricular paroxysm was a terminal event, as four-fifths of 50 cases with ventricular tachycardia described by Strauss died within periods varying

from three hours to six months after the onset of ventricular tachycardia, with an average of 24 days. For these reasons it is thought that the proportion of ventricular to supraventricular tachycardia is exaggerated in the table and cannot amount to more than 20 per cent. of all forms of paroxysmal tachycardia. In those who are subject to attacks of paroxysmal tachycardia extending over years a supraventricular type will usually be demonstrated by the electrocardiograph, in which the nodal type predominates.

General Symptomatology.

The attack.—It is unnecessary to dwell at any length on those well-known characteristics of paroxysmal attack which are common to all varieties of paroxysmal tachycardia, at whatever site the paroxysm is generated. The abrupt onset and the equally abrupt termination of the attack distinguish this syndrome from any other form of palpitation.

Prodromal symptoms are usually conspicuously absent, and the patient is taken completely unawares. Gallavardin and Froment [24] quote the case of a man, aged 48, who for two days before an attack had an exceptional feeling of well-being, and a woman of 52 years who was warned by an exceptional thirst. In another woman the attack appeared within the three days preceding the onset of menstruation, in whom when pregnant the attacks continued to appear each month at similar dates. Prodromal warnings have not occurred in any of my patients.

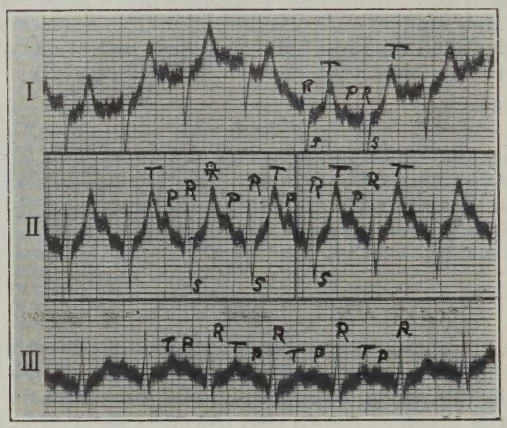
Exciting cause of the attacks.—In most patients the attack sets in without warning and without a definite exciting cause, sometimes even during complete relaxation and rest. In a few there are exciting causes which the patient learns to avoid; prolonged physical effort, such as playing football, would with certainty produce an attack in one of my patients, and in another quick walking after a heavy meal would invariably produce an attack. The bending movement required to put on shoes is particularly prone to produce a paroxysm, and nearly all patients avoid this by standing and putting a foot on a chair. In one of my patients who has only had four attacks in four years the attack seemed to be induced on two out of the four occasions by the enforced holding of the breathing during the excessive effervescence of a Seidlitz powder. In some nervous patients the original first attack of paroxysmal tachycardia may have had an unusual emotional cause; for instance, one patient was terrified by the bursting of a thunderbolt within a few yards of her and the heart immediately broke into a first attack of tachycardia; a boy caught stealing apples and a girl frightened by a dog jumping at her throat were both suddenly seized with their first attacks, to be repeated without apparent cause through the years to come. Goodman and de Graff [28] quote a curious case of a girl, aged 13, with advanced rheumatic heart disease in whom pressure over the heart caused a sudden quickening of the ventricular rate to 170, while the auricles continued to beat at 80 per minute.

Observations During an Attack.

When an attack is launched various observations may be made on the patient's general condition, and on the condition and behaviour of individual organs and systems.

The rate of the heart is of interest in all cases. In all forms of tachycardia the ventricular speed usually lies between 150 and 260, figures below and above these limits being comparatively few. A regular ventricular speed in the neighbourhood of 180–200 would always suggest a regular tachycardia of abnormal supraventricular or ventricular origin. Prolonged and regular ventricular rates of approximately 150 are compatible with a 2 : 1 auricular flutter, indicating an auricular speed of 300. The rate during an individual attack of paroxysmal tachycardia remains fairly constant during that

Electrocardiogram 1.



Auricular tachycardia. Rate = ca 165.

attack. At the instigation of Lewis, Feil and Gilder [20] found that the variation was less than 0·01 second in eight cases of various regular tachycardias, though slight differences, such as 180–184 and 204–210, are frequent. In prolonged seizures there may be greater variation in speed. Marvin [55] noted the gradual slowing of rate from 172 to 124 during five days, and Ritchie [69] noted that a rate of 190 fell to 120 a few hours before death without any change in the tachycardic mechanism. The last observer found in one patient that the rate was quicker when the patient was lying down (228) than when standing up (214). Excessive rates are rare; Langley [40] quotes the case of a boy of 14 years whose ventricular rate was 300.

The heart.—It is primarily important to ascertain if there is any evidence of organic disease of the heart and the cardiovascular system, and a final opinon may be impossible during the attack. It may be convenient at this stage to assess the incidence of organic heart disease in those subject to attacks of paroxysmal tachycardia. Gallavardin and Froment,[24] analysing 177 cases of supraventricular tachycardia, came to the conclusion that there was no evidence of organic cardiovascular disease in 110; in other words, that the examination of the cardiovascular system both during attacks and in normal periods was completely negative in nearly two-thirds of their cases. From a study of the literature it must be confessed that a true estimate of the incidence of organic cardiovascular disease is not always easy. It is often difficult to be certain of the exact type of paroxysmal attack contained in the analysis, and it is essential to separate the supraventricular from the ventricular types, as the latter are much more closely associated with organic heart disease than are the supraventricular types. Other authors put the proportion of organic cases at a lower figure; Hoffmann, Huchard, Chauffard, Mecklen, and Vaquez (quoted by Gallavardin and Froment) estimate that only one-fifth of all cases have organic disease. My own figures show that in patients, whom for the most

part I have been able to follow for many years, there was no evidence of cardiovascular disease in 30 out of a total of 48 with supraventricular tachycardias. Table II. shows the type of cardiovascular disease associated with supraventricular tachycardia.

TABLE II.

Own Cases.			*Gallavardin and Froment.*

Arterio-sclerosis	6				
Myocardial degeneration	7				
	18	% (37·5)			
No cardiovascular lesion	30	(62·5)	No cardiovascular lesion	110	(62·2)
	48			177	

It is very different, however, when inquiry is made into the incidence of organic heart disease in patients who are subject to attacks of ventricular tachycardia. Strauss[77] has analysed the histories and cardiovascular states of 64 patients who were subject to attacks of ventricular tachycardia and in only 11 was there *no* evidence of cardiovascular pathology. Table III. shows the varieties of cardiovascular disease discovered in 53 out of 64 patients:—

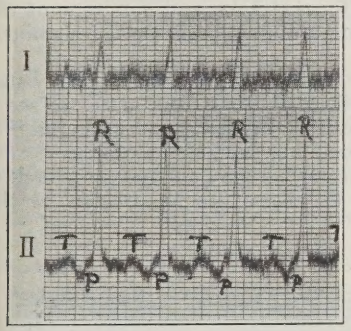
TABLE III.

Cardiovascular hypertensive disease	16
Coronary disease	12
Rheumatic heart disease	8
Arterio-sclerotic heart disease	4
Syphilitic heart disease	4
Thyrotoxic ,, ,,	2
Type of heart disease not clear	7
	53

It seems to be a fair deduction from these tables that no evidence of cardiovascular disease will be found in two-thirds of patients with supraventricular tachycardia and that cardiovascular disease *will* be found in four-fifths of patients with ventricular tachycardia. Certain observations have been made on the *alteration in size of the heart* during the attack. Wenkebach observed that there was no dilatation, whilst Vaughan (quoted by Miller, Smith, and Graber[57]) estimated an increase of 1 cm. and Wilson [84] an increase of 2·5 cm. during attacks observed by them. Stewart and Crawford[76] studied the effect of regular and irregular tachycardias on the size of the heart by means of the X ray shadow. The experiments were conducted on normal anæsthetised dogs and they came to the following conclusions: (1) during regular tachycardias there was a decrease in the size of the heart; (2) that in auricular fibrillation the size was unchanged or increased.

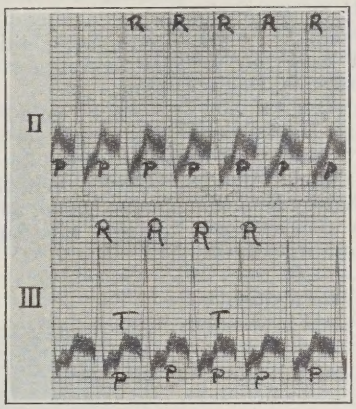
When attacks are prolonged up to four and five days there is often gross clinical evidence that the apex has moved outwards, and this is especially likely to occur in those patients with accompanying organic lesions. In a patient of my own, a boy of 17 years, who had fibrous myocarditis (post mortem) after an attack had lasted three days the apex moved outwards and there were obvious signs of congestive failure in the lungs with oliguria. The appearance of these signs is very uncertain and an attack may last for several weeks without the appearance of any sign of congestive failure, and in this respect much depends on the presence or absence of organic heart disease. It has often been noted that organic heart murmurs present in normal intervals disappear during an attack of tachycardia.

Electrocardiogram 2.



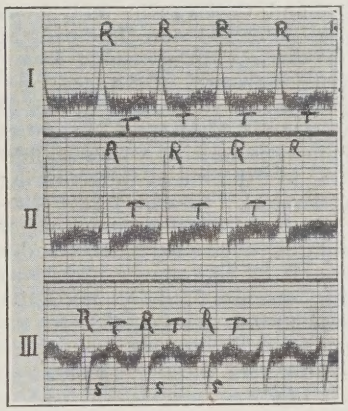
Superior nodal tachycardia. Rate = 187.

Electrocardiogram 3.



Inferior nodal tachycardia. Rate = 200.

Electrocardiogram 4.



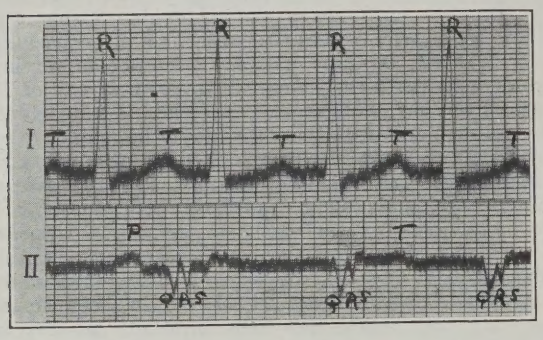
Nodal tachycardia. Rate = ca 170.

Pain of an anginal character occurs infrequently. Willius and Barnes [5] recorded severe chest pain in 5 per cent. of 380 cases and Gallavardin and Froment[24] in one-seventeenth of 177 cases. In many the pain did not occur until the later attacks in a patient's life and usually after an attack had lasted many hours. In one of my patients it occurred after an attack had lasted five hours and that attack had been preceded by a particularly fatiguing and anxious day. It required morphia for its relief, which brought about sleep, and when the patient awoke the attack had ended. In my private patients chest sensations, varying from oppression to actual chest pain, with pain or numbness in the arms, is more common than in hospital patients and there were definite chest discomforts in 16 per cent.

Blood Pressure.—(*a*) Arterial pressure usually falls during an attack. A pressure varying between 165/100 and 190/115 in the inter-paroxysmal period fell to 130/95 during an attack (Hirschfelder, quoted by Miller, Smith, and Graber[57]) and in another patient there was a fall from 190/115 to 95/85 during an attack with a ventricular rate of 200 (Willius, quoted by Miller, Smith, and Graber[57]). There seem to be several causes for the fall of arterial blood pressure: (1) The shortened diastole causes a diminished systolic

output; (2) the contractile power of the ventricles is lessened by the shortened diastole; (3) the simultaneous contraction of auricles and ventricles in nodal tachycardia would tend to diminish the output from the ventricles. On rare occasions the blood pressure

Electrocardiogram 5.



Nodal tachycardia. Lead I. shows the paroxysm. In lead II. the first complex shows normal rhythm, the other two the onset of a paroxysm; the QRS complexes are common to both. Rate = ca 187.

rises and Gallavardin and Froment[24] quote a rise from 120 to 160 mm. Hg during an attack.

(*b*) Certain observations have been made on the venous pressure. In a case of paroxysmal tachycardia with a ventricular rate of 220 the arterial blood pressure fell from 135/85 to 120/110 mm. Hg, and the venous pressure rose from a normal of 105 mm. of water to 210 mm. of water during an attack (Hooker and Eyster).[34] Similarly, in a case quoted by Kroetz[39] in which there was a heart rate of 220 with cyanosis, dyspnœa, liver enlargement and albuminuria, during the attacks the venous pressure rose to 160 mm. of water and was found to be 50 mm. of water after the cessation of the attack. In paroxysmal auricular fibrillation the venous pressure rose from 80–90 mm. of water and the ventricular rate increased from 84 to 108 (Eyster and Middleton).[19] Eyster[18] concludes, "that venous pressure may or may not rise in paroxysmal tachycardia and paroxysmal auricular fibrillation depending upon whether or not cardiac incompetence supervenes."

Blood gases.—Barcroft, Bock, and Roughton[2] have summarised the changes in the blood gases as follows: (1) there is a marked decrease of arterial oxygen saturation without demonstrable pulmonary congestion; (2) there is a low CO_2 content of arterial blood during the paroxysm; (3) there is a very low oxygen saturation of venous blood, part of which they attributed to anoxic anoxæmia due to slowing of the circulation; (4) there was a greatly increased coefficient of utilisation during the paroxysm indicating a very slow circulation-rate; (5) there is a decrease in vital capacity immediately following the paroxysm.

The patient's tolerance of the attack varies a good deal and the varying degrees of discomfort experienced by different patients is inexplicable. I have gone into the question with 34 of my patients who have been under observation for many years and the degrees of discomfort and distress in each attack are very constant to the individual. The results may be summarised as follows:—

Severe (prostration)	11
Moderately severe (necessitating recumbency) ..	15
Trivial (able to go about)	8
	34

Though most patients prefer to rest, and to sit rather than to lie, there are those who can move about quite freely. One of my patients, at the age of 60 years, who had suffered from attacks for 25 years, was able to walk up one of the steepest banks of our district in the full flood of an attack. The commonest complaints are of giddiness, faintness, exhaustion, and in some absolute prostration. The rapid and violent beating of the heart distresses the patient considerably and after the attack there is usually a feeling of exhaustion.

Occasionally *nervous symptoms* may be dominant and Barnes[4] quotes 15 cases, of whom ten were males, where the nervous manifestations were prominent, and Table IV. shows the type of nervous derangement:—

TABLE IV.

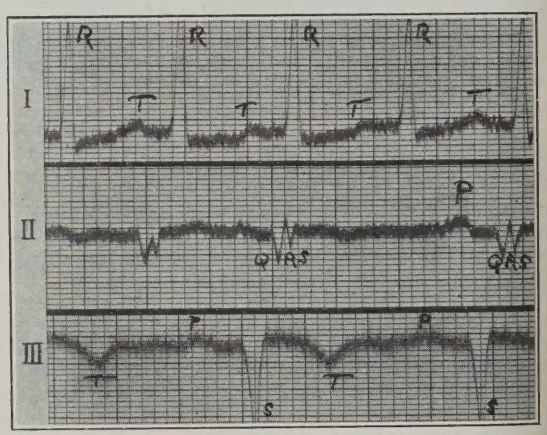
Vertigo	8
Temporary blindness	6
Falling but no loss of consciousness	5
Syncopal attacks	4
Epileptiform seizures	2

These symptoms were interchangeable amongst the 15 patients. Ritchie[69] states that nervous symptoms were marked in 15 out of 104 cases. Wilson[84] quotes the case of a man aged 38 years subject to attacks of auricular paroxysmal tachycardia which would sometimes last eight days, in whom during different attacks there occurred aphasia, hemiplegia, epileptiform attacks, and gangrene of the left arm necessitating amputation below the shoulder-joint.

Some would seem to suggest that paroxysmal tachycardia is an allergic disease and claim to see a relationship between it and asthma and migraine.[42 79] I have not encountered any such associations.

The *actual termination* of the paroxysmal attack is abrupt, but before the complete restoration of the

Electrocardiogram 6.



Nodal tachycardia. Lead I. shows the paroxysm, which ceases at the last complex of lead II. Lead III. is the normal rhythm. Rate = ca 160.

normal rhythm there may be some irregularities, and the following are the chief mechanical modes of ending:—

(*a*) Abrupt transition from the attack to the normal rhythm.

(*b*) The last beat of the paroxysm is followed by the appearance of ventricular extrasystoles, either singly or in salvoes.

(*c*) The last beat is followed by a series of slow pulsations with a negative P in the electrocardiogram.

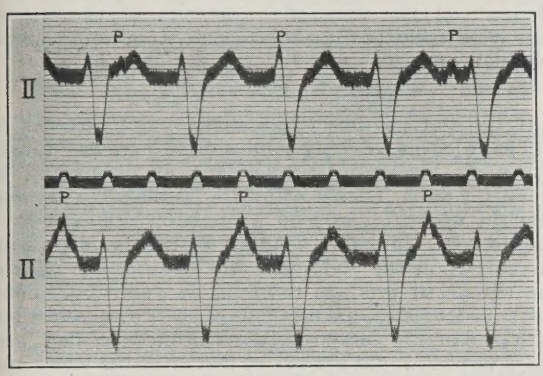
(*d*) A slow nodal rhythm succeeds the paroxysm for a few seconds. After the paroxysm the normal rate is usually

somewhat quickened before it settles down to the normal for the individual. The method of termination is not always constant in the same patient.[24]

Frequency and Duration of Attacks.

There is the greatest variation in the frequency with which patients are liable to have attacks. I have come across undoubted examples of a single attack

Electrocardiogram 7.



Ventricular tachycardia. Rate = ca 150.
(Dr. John Parkinson's case.)

n a lifetime. I saw such an attack in a child 21 years ago who has never had a second attack. When nembers of our profession describe in their own persons a typical attack, with abrupt onset and offset, here can be no question of wrong diagnosis, and I have come across two instances of single attacks in doctors. f an individual experiences a single attack and there s no recurrence he assumes it to be an unusual palpitation, and if it never recurs he does not seek medical dvice and may never mention to anyone his soon orgotten experience.

In those subject to repeated attacks the frequency aries greatly. At first the intervals between attacks nay be long, and later in life they may become much hortened. A man of 70 years had 34 paroxysms in 7 days lasting from 8 to 14 hours and then only had hree attacks in five months (Corney). One of my atients since 1922 has had about 100 attacks each ear. Many have had frequent attacks over a period f two to three years and then have had long intervals ith few attacks, and I have been unable to find any xplanation for the variation. The frequency of ttacks is often in inverse ratio to the length of the ttacks, and the longer the preceding attack has been ne longer will the patient wait for the next attack. here is no doubt also that the liability to attacks may ompletely disappear. In two of my patients there ave been no attacks for seven to eight years although ney had been frequent in the previous four years.

The *liability to attacks* may extend over the whole a lifetime and one of my patients has had infrequent ttacks for 52 years, though the average duration in 2 of my cases was 15½ years. The repeated attacks pose no lasting disability on the heart and my atient, a busy doctor, subject to attacks for 52 years, as to-day a cardiovascular system perfectly normal r his years. Cowan tells me of a patient under his re for many years, who was subject to attacks from e age of 18 years to his death at the age of 75—57 ars—who was a busy member of the legal profession, ached the Bench, and made speeches in the House of ommons in the full flood of a paroxysm.

The length of individual attacks also shows great variation, but the vast majority are of less than 12 hours' duration (Table V.).

TABLE V.—*Showing the Longest Attacks to which Patient was subject.*

	Gallavardin and Froment.	Own cases.
Less than 12 hours ..	113	36
12–24 hours	27	8
24–48 hours	16	2
2–5 days	6	0
5–10 days	4	1
10 days–1 month	7	1
1 month–2 months ..	3	0
Up to one year	1	0
	177	48

Scattered through the literature attacks of exceptional length can be found—namely, 15 months (Ritchie).[69] Rarely do attacks last for more than ten days. In 160 cases quoted by Gallavardin, Veil, and Froment, 11 had attacks lasting more than ten days. Seven had attacks lasting from ten days to one month, and in four there were paroxysms lasting from 1 to 12 months. In some of the prolonged attacks it is difficult to be certain that there are not temporary cessations, and in a woman with organic heart disease whom I saw in her home the attack was said to have lasted eight months, but during my visit I detected three short pauses and it is probable that throughout the eight months temporary breaks occurred, without the patient's knowledge and unnoticed by her attendants. She died with congestive failure a month later without noticeable cessation of the paroxysm. (Not included in above Table.)

Sex.—The incidence in the sexes is almost equal—the proportion being given by Gallavardin and Froment[24] as 82 men to 95 women, and by Willius and Barnes[5] as 59 men to 51 women, which is probably the correct relationship, though my own figures show 34 males to 16 females.

Age.—The average age at which the attacks *started* was 36 years in 34 of my patients, in whom the date could be accurately determined, the youngest being six years and the oldest 73 years (nodal type). Table VI. sets out the ages at *onset* in decades.

TABLE VI.

10–20 years	8	60–70 years ..	5
20–30 „	7	70–80 „	1
30–40 „	4		
40–50 „	5		34
50–60 „	4		

Though the youngest patient in my series was 6 years old, attacks of paroxysmal tachycardia have been described from infancy onwards. The earliest record I can find was that described by Werley[82] in an infant 4 days old who developed a ventricular rate of 307. The attack passed off in a few hours. This was succeeded by another attack with a ventricular rate of 300 and respiration rate of 70, and the child was very cyanosed. The infant died on the sixth day and the only cardiac abnormality was a widely dilated foramen ovale (7 mm.). Attacks have been described at the age of 15 months (Russell and Ellison),[71] 27 months (Dressler and Levy),[16] and 32 months (Hutchison and Parkinson).[36] As I have already mentioned, it is extremely probable that unique attacks may occur in adults and isolated attacks may be completely overlooked in the young.

Ætiology.—It has been mentioned that the prime factors of causation of an attack of paroxysmal

tachycardia are still obscure, and the diversity of circumstances in which attacks appear makes this unsatisfactory admission quite comprehensible.

Heredity plays little part in most cases. Attacks have been described in four generations, and two of my patients are sisters—one with arterio-sclerosis and a blood pressure of 200 for ten years—and the other with a normal cardiovascular system. Infectious diseases, thyroid and ovarian derangements have been invoked but without any weight of evidence. Hypothetic nerve influences through the vagus and sympathetic nerves and actual involvement of these nerves by cervical and mediastinal tumours have been cited but do not convince. Morbid anatomy has failed to demonstrate any pathological lesion in the heart musculature, and none would be expected in a condition lasting so many years without any other evidence of cardiac involvement.

Diagnosis.

If an electrocardiogram is obtainable during a paroxysm, with some exceptions, a diagnosis of the exact type of tachycardia can be made. A *regular* tachycardia will conform to the electrical characteristics of a regular auricular flutter—e.g., 2 : 1—a supraventricular or a ventricular tachycardia. Secondly, the patient may be seen in an attack but there may be no opportunity of obtaining an electrical record. Without this assistance can a diagnosis be hazarded as to the particular type of tachycardia?

(*a*) If the ventricular rhythm is very *rapid and irregular* the probability lies between paroxysmal auricular fibrillation and auricular flutter. When the ventricles keep changing their response to the auricular stimulus in auricular flutter the irregularity determined by the stethoscope may be very complete and simulate fibrillation of the auricles. In auricular flutter, however, there are frequently periods when the ventricular rhythm is quite regular, as it is if the response is 1 : 1 or 2 : 1, so that long runs of regular ventricular contractions appearing from time to time interspersed amongst periods of irregularity would suggest auricular flutter. After all, the distinction is not so very important, as treatment by digitalis is indicated in both conditions. Vagal pressure in the neck will usually temporarily arrest or slow the ventricular rate in both paroxysmal fibrillation and flutter, but will not stop the attack.

(*b*) If the ventricular rhythm is very rapid and *regular* we have then to differentiate between a regular auricular flutter—e.g., 2 : 1 flutter, a supraventricular tachycardia, and a ventricular tachycardia. Again, vagal pressure may assist in the differentiation. If the attack is arrested then it is certain that the attack is supraventricular, vagal pressure having no influence on ventricular tachycardia and merely temporarily arrests or slows the ventricular speed in auricular flutter. If there is no response to vagal pressure—not even temporary arrest or slowing of the ventricles (auricular flutter)—the alternatives are supraventricular or ventricular tachycardia. If the patient is under 40 years of age, has been previously subject to attacks, and has no obvious cardiovascular disease, the enormous probability is that he is subject to attacks of supraventricular origin. If, on the other hand, he is over 40, and more probably between 50 and 60 years of age, if there is cardiovascular disease and the patient has only recently become subject to attacks, the paroxysm *may* be ventricular, though it is possible that the attack is supraventricular in origin. When only a history can be obtained and there is no opportunity of witnessing an attack the diagnosis of paroxysmal tachycardia may be obvious, but a surmise of its origin must be very speculative. The patient or an attendant may know whether the heart beats quite regularly in the attack and this fact, together with the other general considerations of age, the presence or absence of cardiovascular disease, and the length of time the attacks have lasted will all help to suggest the type.

Therapeutics.

The treatment may be considered from three points of view: (1) the arrest of the attack; (2) the prevention of attacks; (3) the treatment of any cardiovascular disease.

ARREST OF AN ATTACK.

If the patient has experienced many attacks he will have learnt to apply some simple "tricks" taught either by his medical attendant or discovered by himself. Such tricks comprise swallowing a long draught of water, a deep inspiration followed by a long forced expiration, bending forwards and pressing the thighs on the abdomen, and tickling the back of the throat to produce retching or vomiting. Some patients devise special methods of their own, and a boy with rheumatic heart disease confined to bed with heart failure would get out of bed after the onset of a paroxysm, would stand motionless with his back to the edge of the bed, hold his breath as long as he could, and when he could hold it no longer he violently threw himself backwards on to the bed. I saw him arrest many attacks in this way. The production of vomiting by emetics such as apomorphine has been advocated by some, but is not to be recommended if retching after tickling the throat does not arrest the attack. The vomiting produced by ipecacuanha and apomorphine may, in my own experience, cause great prostration and never brought an attack to an end.

The earlier in the attack that these various procedures are tried the more likely they are to be efficacious. If they have failed the next step is to compress the vagus in the neck. Theoretically, the right, supplying the sino-auricular nodal region, ought to be more effective than the left, but I usually employ the left and if left vagal pressure has failed I have never succeeded with the right. Some paroxysms of supraventricular tachycardia are immediately arrested, and though no statistics are available Gallavardin and Froment[24] claim that nearly one-half of supraventricular paroxysms may be arrested by vagal pressure. My own experience more nearly approaches success in one-sixth. Some paroxysms are arrested and the rhythm remains normal from 10 to 15 minutes, but the attack recommences and further vagal pressure is ineffective. Vagal pressure also is more effective early in the attack. I have two patients who have learnt to compress their own left vagus, and they always succeed in arresting a paroxysm by this means. Whether vagal compression succeeds by direct stimulation of the vagus nerve or by stimulation of the nerve of Hering, arising in the carotid sinus and reaching the medulla by the glossopharyngeal nerve, is an interesting physiological question. If vagal compression fails, ocular pressure with the thumb and index finger on the eyeballs may be essayed. This manœuvre succeeded in one case where vagal compression had failed. I have had no experience of the injection of ouabaine, physostigmine,[24] digitalis,[86] and choline, which have been recommended after apparent individual successes.

The above measures are applicable to paroxysms

with a supraventricular origin. In ventricular tachycardia quinidine sulphate has been advocated, and with some success. Levine and Fulton [47] recommend an initial dose of 0·3 g., raising the dose every four hours by 0·1 to 0·2 g. In one case they gave 1·5 g. five times in 24 hours, and in eight cases out of ten quinidine sulphate caused a return to a normal rhythm. Eight out of ten cases had coronary thrombosis and seven died, though the paroxysms were arrested. Ventricular tachycardia is a serious addition to the heart failure of coronary thrombosis but the ultimate prognosis depends on the degree of coronary blocking rather than on the added disability of ventricular tachycardia.

The lines of most effective treatment can be summarised. In supraventricular tachycardia after the various "tricks" have failed, vagal compression is successful in a definite proportion of cases, and no other remedies have been proved to be of general applicability. In ventricular tachycardia quinidine sulphate is immediately necessary, as the procedures effective in supraventricular tachycardia are quite ineffective.

PREVENTION OF ATTACKS.

Many patients know by experience that certain circumstances, such as peculiar movements, indigestion, and emotional causes, precipitate attacks and endeavour to avoid them. The frequency of attacks of paroxysmal tachycardia varies so much naturally that it is difficult to gauge the success of any line of treatment in the prevention of their recurrence. I have some evidence that quinidine sulphate in daily doses of grs. 6 diminishes the number when these have been excessive for a long period. For example, one man who had for three years experienced about a 100 annually had only about 30 each year after he took quinidine grs. 6 daily.

The treatment of any underlying cardiovascular disease is outside the scope of this inquiry and would necessarily embrace the whole range of cardiovascular disease.

CONCLUSION.

In conclusion, attacks of paroxysmal tachycardia are a common disability, occurring most frequently in those who are free from any suspicion of cardiovascular disease, but also in association with various forms of heart disease. In neither class have we any reasonable explanation of its appearance. The exciting focus is most commonly in the junctional tissues above the ventricles, and supraventricular tachycardia may harass an individual throughout a lifetime. Ventricular tachycardia is rare except as a terminal event in gross organic heart disease, which is usually fatal within a few months. Electrocardiographic and experimental research has given us a greater insight into the cardiac mechanism of paroxysmal tachycardia and the accumulated clinical experience allows us to speak with greater assurance as to prognosis and treatment.

GLASGOW HOSPITALS.—The new radiological department of the Western Infirmary has now been formally opened by Mrs. R. S. MacGregor who, with her husband, was among the largest contributors to the cost. It was stated that ten years ago the number of X ray photographs taken was about 6000, but that this year the number has increased to over 19,000.—Mrs. McCredie, daughter of the Lord Provost (Mr. Thomas Kelly), has opened an extension of the country branch at Drumchapel of the Royal Hospital for Sick Children. The enlargement consists of three main wards, two isolation wards, and a nurses' home. The branch will now accommodate about 80 children.

FILTER-PASSING TRANSMISSIBLE BACTERIOLYTIC AGENTS (BACTERIOPHAGE).

By Frederick William Twort, M.R.C.S. Eng., F.R.S.,

SUPERINTENDENT OF THE BROWN INSTITUTION, UNIVERSITY OF LONDON.

In my paper entitled An Investigation on the Nature of Ultramicroscopic Viruses, published in The Lancet of Dec. 4th, 1915, I gave a broad description of the essential characteristics of the filter-passing transmissible bacteriolytic agents, now frequently described under the name of "the bacteriophage."

I showed that they could be found associated with various micrococci and with members of the dysentery-typhoid-*coli* group of bacteria, and that they possessed different degrees of activity. Unfortunately, I had no opportunity for some years to continue the research, but I discussed the significance of the phenomenon, and the variations which had been observed, at the annual meeting of the British Medical Association at Glasgow in 1922, and in several papers published a little later.

A very large number of researches on the phenomenon have since been carried out by workers in almost all countries. D'Hérelle, in particular, has made an extended investigation into most aspects of the subject. It has been suggested that the active agent, described by d'Hérelle under the name of "the bacteriophage," differs from the agents I described in my original paper. Although nearly 15 years have elapsed since my first publication, this view is still sometimes put forward, and appears to be based, partly at least, on a very narrow and critical interpretation of a few words and sentences in my paper.

In view of the importance which some workers attach to the small differences in some of the results we have described, and to the fact that d'Hérelle himself has again invited me to reply, I propose, in this short paper, to relate the circumstances which determine those differences, and to explain a little more fully a few facts given in my first paper, which may have been either overlooked or not fully understood, in the hope that other workers will then be in a better position to appreciate their significance.

In the first place, it is well to remember that human knowledge has advanced in all countries much more rapidly than has our means of expressing that knowledge in words. When, then, a description has to be short, the writer can only select the best words available from a language that has lagged behind knowledge, to describe his thoughts or experiments. I therefore ask readers of my original paper to judge my meaning from the paper as a whole, and not to select individual words or short sentences, and place these under a too narrow or exacting scrutiny, particularly where small variations in experimental technique may give rise to quantitative variations in results, or where a description has had to be condensed into a few words.

Nature of the Active Agent.

The nature of the active agent has been the subject of considerable controversy, some workers agreeing with d'Hérelle that it is a living virus, and some maintaining that it is not. I have observed that certain workers appear to believe that I am definitely against the virus theory. I wish therefore to make it quite clear that none of my writings is intended to convey that meaning. My attitude is that the nature of these agents is *not settled*. There are arguments that can be brought forward both for and against the virus theory, and I suggest that it is not in keeping with scientific principles to make a dogmatic assertion one way or the other until definite proof is forthcoming. This was the attitude I took up in my original communication, where I considered the possibility that it might be a virus, as well as various other possibilities. Moreover, I have discussed this question in considerable detail in two more recent papers.[1] This aspect of the subject cannot here be discussed *briefly* with any certainty that I will be correctly understood, so I hope readers will refer to these previous papers if they desire to become acquainted with my views.

In the past I have frequently alluded to the active agent as the bacteriolysin, but in this paper and in future writings I propose to refer to it either as "the bacteriophage" or as "the filter-passing transmissible bacteriolytic agents." The name "bacteriolytic agents" is probably less confusing than that of "bacteriolysin." When speaking of them as a group I may use the word agent in place of agents; and I may also use agent when describing the results of d'Hérelle, as I believe d'Hérelle is still of the opinion that there is only one bacteriophage. It will not always be necessary to use the full title, and in such cases "the lytic agent" or "the active agent" will be sufficient.

It has been observed that the characteristics of the filter-passing transmissible bacteriolytic agents which I described show that, in some respects, my results indicate a more complete action than that obtained by d'Hérelle for such a bacterium as the dysentery bacillus. I, however, would point out that my main description was based, chiefly, on the maximum effect I could obtain with an active agent and a susceptible micro-organism; and my detailed description applies particularly to micrococci and lytic agents which I obtained from glycerinated calf vaccinia lymph. I agree that the action may be much less complete with some strains of the lytic agents and with certain varieties of bacteria. In my paper I drew attention to that fact, and pointed out that my vaccinia strain of the active agent had some action, but "very much less" on *Staphylococcus aureus* and *albus* isolated from boils of man. Also, that I obtained "similar, though not such definite results with a micrococcus and a member of the *coli*-typhoid group" obtained from the intestine of a dog. On the other hand, a very active lytic agent was obtained from a case of infantile diarrhœa and vomiting in a child. It will be seen therefore that I agree as to the existence of filter-passing transmissible bacteriolytic agents possessing various degrees of potency, and recognise that different micro-organisms may possess different degrees of susceptibility. D'Hérelle, in his writings, maintains that there is only one bacteriophage, and, in effect, wishes to limit the use of this name to a particular strain. If, however, the name "bacteriophage" is to be retained, it can scarcely be applied to the intestinal strain, or type, isolated by d'Hérelle without its being also applied to the three intestinal strains which I had previously isolated. I suggest also that no evidence has been

[1] A Theoretical Study of the Nature of Ultra-microscopic Viruses, Veterinary Journal, August and September, 1922; and the Ultra-microscopic Viruses, Jour. State Med., August, 1923, vol. xxxi., p. 351.

brought forward that would justify our placing the strains I isolated from vaccinia in a different category.

When describing one of my experiments, I observed that when a pure culture of "the white or the yellow micrococcus" isolated from vaccinia is touched with lytic material, it "starts to become transparent or glassy, and this gradually spreads over the whole growth, sometimes killing out all the micrococci." To some workers this description indicates that my active agents differ from that described by d'Hérelle, as with his the action will not spread over the "whole" growth. André Gratia has shown that it is really a case of quantitative effect, and with this view I agree. In the sentence given above the word "whole" was not intended to be interpreted in its narrow sense under all circumstances and conditions, as is clearly shown by the use of the word "sometimes" which immediately follows. This is emphasised by the next sentence, which reads: "Experiments showed that the action is more rapid and complete with vigorous-growing young cultures than with old ones."

Conditions Favourable to Bacteriolysis.

Under very favourable conditions, it is possible to get a white or yellow micrococcus growth (isolated from vaccinia) so completely lysed that to the naked eye it appears to be entirely replaced by, or transformed into, a glassy, transparent or translucent substance. To obtain this maximum effect, the following conditions should be observed:—

(1) The lytic agent should be active. (2) The coccus should be susceptible, and must be the correct variety for the active agent used. (3) The culture should be very young. (4) The culture should be limited in extent, preferably to the lower part of the tube. (5) The medium should be in every way suitable to the lytic agent, and, in some cases at least, should be slightly alkaline. (6) The temperature should be suitable for the particular lytic agent used. (7) Plenty of moisture is advisable. (8) Probably the supply of oxygen should be limited.

It may be noted that capping the culture tube with gutta-percha tissue will assist in obtaining the last two of the conditions given above.

With further reference to the question of anaerobia, I have in the past stated that this does not favour the action. I believe, however, that this is due chiefly, if not entirely, to the fact that, under strict anaerobic conditions, the growth of many micro-organisms is either stopped or so far hindered that it becomes unsuitable for the action of the lytic agent; because an actively growing culture (although in the first few hours growth may not be visible) is probably one of the most essential conditions. It appears probable, however, that the lytic agent does not require a free supply of oxygen, for, in the case of some vaccinia micrococci and various members of the dysentery-typhoid-*coli* group of bacteria, the maximum *visible effect* of the lytic agent, in some experiments, occurs when the cultures are capped and are growing well; and we know that under these conditions the medium may be deprived of a large part of its absorbed oxygen.

That the correct temperature and correct oxygen supply are two of the important factors which determine the degree and rapidity with which lysis may take place is indicated by another aspect of the subject on which there has been some controversy. In my first paper occurs the statement that "if in an infected tube small areas of micrococci are left, and this usually happens when the micrococcus has grown well before becoming infected, these areas will start to grow again and extend over the transparent portions." Some workers have failed to obtain this result with "bacteriophages," so I propose to give shortly the conditions which should be observed in order to obtain this result. I would point out at once that the extension of the remaining coccus growth over the lysed areas will not as a rule extend far, owing to the exhaustion of the medium; but under suitable conditions a considerable extension can be obtained. The chief conditions that favour this result are:—

(1) The reaction of the medium should be more suitable to the growth of the coccus than to the action of the lytic agent.

(2) The culture should at no stage have become so overgrown with the coccus or bacterium that it has become exhausted of nutriment.

(3) The temperature should be changed from that most suitable to the action of the lytic agent to that which is relatively more suitable to the growth of the micro-organism. Under the conditions of the experiment it is best, with many types, to lower the incubator temperature to about 20° C. to 30° C.

(4) With aerobic micro-organisms the tube should be uncapped, to allow of a free supply of oxygen, and possibly some evaporation of moisture.

One may conclude, then, that this character is most easily demonstrated with an aerobic micro-organism which will continue to grow at a temperature and under conditions that are relatively less suitable for the action of the lytic agent.

It has also been said that in my first description of the lytic agents I made no allusion to the so-called inhibitory action, which is claimed to be a characteristic of the bacteriophage. I would, however, draw attention to various descriptions in my original paper which show clearly that I obtained these so-called inhibitory results. For instance, I stated, "and in some cases it is so active that the growth is stopped and turns transparent almost directly it starts." Further on, when describing the isolation of a bacillus from a case of infantile diarrhœa and vomiting, I stated, "but this was only so when precautions were taken to eliminate the action of a dissolving substance which infected the colonies so rapidly that they were dissolved before attaining a size visible to the eye." It is true, I did not describe these as inhibitory actions. On the contrary, I deliberately refrained from doing so, and for this reason: I had already shown that the lytic agent had little or no effect on dead micro-organisms, and from that I concluded that life with some growth of the micro-organism (however small or microscopic it might be) was essential to the action of the agent. In fact, I believed that some microscopic degree of growth always took place, even when the experiment *appeared to show* a true inhibitory action. Gratia demonstrated this on *Bacillus coli* in 1920. If, then, there is any divergence in this class of experiment, it is not in the results obtained, but only in the conclusions which some workers and myself have drawn from those results. That the action described as inhibitory and the action of lysis of visible growth are in fact manifestations of one and the same phenomenon has been very completely demonstrated by Gratia. At the meeting of the British Medical Association at Glasgow in 1922, Gratia showed a beautiful series of experiments in which he used the *same* filter-passing agent under varying conditions of experiment, and obtained the one or the other manifestation of the phenomenon according as he varied those conditions.

Another point in my original paper that has occasionally been considered as not applying to the

bacteriophage is my observation that "on examination of these glassy areas nothing but minute granules, staining reddish with Giemsa, could be seen." It has been said that these granules do not occur with the true bacteriophage. I would, however, point out that to find many of these granules it is necessary to repeat my experiment and to examine the material in its most concentrated form, such as occurs when surface growth has been lysed. In my paper I made no suggestion that the granules could be easily found and distinguished in fluid cultures, or in cultures that showed no visible growth of the micro-organism. Moreover, it is probable that some, if not all, of these granules represent the remains of the broken-down micro-organism. In this case the number and the size of the granules must depend, to some extent at least, upon the number and upon the variety of the micro-organism that has been acted upon.

The Culture Media.

I wish now to give some consideration to the question of the different types of media that have been used. It has been assumed by some that my results were confined to agar cultures. If, however, reference is made to my original paper, it will be noted that, in the first part, I mention that in my investigation of the ultra-microscopic viruses "several hundred media were tested," and that it was "impossible to describe all these in detail, but generally agar, egg, or serum was used as a basis." Naturally, when testing so many types of media, a certain number of fluids, including broths, were used, and many experiments with the transmissible bacteriolytic agents were made on these media. If my description was based on agar cultures it was because on this medium the fundamental characters of the lytic agent appeared to be demonstrated better than on any other, and circumstances compelled me to be as short and concise as possible. In particular, the experiments on agar demonstrated one of the most important characters of the active agent. They showed that the action started from definite spots or areas, and that these varied in number according to the dilution of the active agent. On the other hand, fluid cultures do not show any fundamental characters that cannot be demonstrated on agar, although for certain experiments broth cultures may be more convenient to use. Here it may be noted that egg media are particularly suitable for use when making primary cultures to isolate some strains of the active agent.

When the action takes place on certain micro-organisms a halo may occur in the medium. This was first described by Gratia, since when there have been discussions as to its significance. I have also observed this character, and here I may say that I have found it to be associated with the production, or setting free, of some alkali or alkaline substance. This is particularly marked when certain micrococci, such as varieties which can be obtained from urine, are lysed by the active agent. From this it would appear that the reaction of the medium and its constitution will have some effect on the result.

Thermal Death-point of the Bacteriophage.

The temperature at which the active agent is destroyed has also been the subject of considerable discussion. In my first paper I gave the thermal death-point as 60° C., whereas d'Hérelle, in his papers, has given it as 70° C., or over, for the bacteriophage. André Gratia and others have pointed out that the critical temperature is relative, and varies with different bacteriophages, and with this view I agree. It must be remembered that my experiments on the thermal death-point were carried out on the lytic agent found in association with white and yellow micrococci isolated from glycerinated calf vaccinia lymph. I did not in that paper give any exact figure for the bacteriophages which I had found in the intestinal tract associated with other bacteria, such as those belonging to the dysentery-typhoid-*coli* group. It must also be noted that the results obtained in such experiments depend, to some extent, on the exact conditions of the experiment, and particularly on the exact constitution of the fluid containing the active agent and on the volume of fluid heated. In my experiments I used a small portion of the glassy lysed coccus, and made this into an emulsion with 0·85 per cent. sodium chloride in distilled water. The emulsion was drawn up into *small capillary tubes*, which were then sealed at both ends and completely immersed in the water bath. Full details of confirmatory experiments were given in my paper on the Transmissible Bacterial Lysin, published in THE LANCET of Sept. 26th, 1925. If these conditions of the experiment are altered in certain directions the thermal death-point may appear to be raised, but in my experiments I took care to avoid any circumstance or condition coming into play that might protect the lytic agent. I, however, agree with d'Hérelle and some other workers that the thermal death-point may be higher than that for the particular strain of the agent which may be found in association with micrococci in vaccinia; and even from vaccinia one can often get a strain that is not completely destroyed at 60° C. It would, indeed, be strange if such a variation did not exist.

Original Studies not Completed.

It is to be hoped that the details I have now given will be sufficient to enable other workers to obtain all the results I gave in my original paper. If the first description of those results was not quite complete in every detail, it must be remembered that it was published in 1915 when circumstances compelled me to be as brief as possible. In any case, it would have been impossible in a single paper to have submitted every aspect of a phenomenon which has since proved to offer such a wide scope for theoretical discussion and experimental investigation. Moreover, in view of certain criticisms that have been made, I feel bound to place on record the fact that my paper was submitted for publication when my financial grant from the Local Government Board ceased and I had been asked to undertake laboratory duties in the Army, and it was actually published only a few weeks before I was ordered to Salonika. From a study of the last three paragraphs of my original paper it will be clear how anxious I was to obtain the necessary filter-passing transmissible bacteriolytic agent for the Shiga and Flexner types of dysentery bacilli, and to test vaccines prepared from the active agent and the lysed bacteria. The matter was brought up for discussion in 1916, at a meeting in Salonika, which was attended also by officers of the French and Canadian medical staffs. Unfortunately, this and other attempts on my part to be allowed to continue the investigation were not approved partly, I think, on account of the amount of routine work which had to be carried out in connexion with the sickness that was prevalent. It was some time after the end of the war before I was really free again to continue the investigation, but by that time most of the additional details of the

phenomenon had been published by other workers under the title of "the bacteriophage." So I passed on to other work.

D'Hérelle, in a communication published in the *Bulletins et Mémoires de la Société Nationale de Chirurgie*, dated May 17th, 1930, complains that I have never answered any question put to me regarding the phenomenon I described. I admit that with one or two exceptions this is true, in that I have, as far as was possible in my writings, avoided entering into a discussion that I believed would serve no useful purpose. This applies to the claim made by d'Hérelle that there are certain differences which represent important points of distinction between his bacteriophage and the filter-passing transmissible agents which I previously described. I was convinced that sooner or later their identity would be recognised, and I felt content to leave this aspect of the subject to the judgment of independent workers.

In the paper to which I have referred d'Hérelle draws attention to the descriptions given by certain workers on *Bacillus pyocyaneus*. It is suggested that some of these results represent a phenomenon that has no connexion with the bacteriophage, but has a certain resemblance to the phenomenon I described. More direct suggestions have also been made in the past that, *unlike those obtained with the bacteriophage*, my results indicate a degenerative process. I must confess I am unable to appreciate arguments of this kind, and I prefer to reply by referring readers to my original paper. I would, however, point out that I have carried out no work on *B. pyocyaneus*.

Properties of the Bacteriophage.

In the same paper d'Hérelle submits that there are three properties, among others, by which the bacteriophage is distinguished. In order that there may be no further complaints regarding my silence I will now consider this claim. The points mentioned by d'Hérelle refer to a certain reaction demonstrated by a resistance of the bacterium to the action of the bacteriophage, and to the character of progressive adaptation to resistance against antiseptics and the production of a specific anti-bacteriophage principle in the blood of inoculated animals. I suggest that these are minor points of detail, where one would expect the results of experiments to vary according to the strain of active agent used. The exact meaning of the first point is not quite clear. If it refers to the production of a strain of a bacterium that is resistant to the action of the bacteriophage, then it will be sufficient to point out that adaptation is a character of bacteria, and it can be demonstrated when bacteria are placed under the influence of some substance which is harmful to them. In the case of immunity reactions in particular it is probable that some strains of the lytic agent would prove to be more toxic than others. It is also possible that the nature of the micro-organism, associated with the agent, will have some effect in determining results. I doubt if the active agent has ever been freed from the products of the broken-down micro-organism, and although these products may not produce their characteristic immunity reactions, they may still be toxic in another way, and so affect the results obtained with different strains of the active lytic agent. If, however, d'Hérelle should show that some strains of the active agent conform to his requirements while others do not, it will be interesting, and his experiments might confirm the generally accepted view that there are more strains or varieties than one. In any case, in my paper I did not describe any immunity reactions, nor did I go into the question of adaptation to resistance against antiseptics. My original strains of the lytic agent died out during the war, and obviously it can never be known with *absolute certainty* to what extent my particular strains would have conformed to such details; but this would appear to be equally true for many strains since described under the name of "the bacteriophage."

As regards my own strains, I would again remind readers that, in addition to those I obtained from vaccinia, I also isolated two from the intestinal tract of a dog and one from the intestinal tract of a child. All these strains showed the same fundamental characters, of which the most important are:—

(1) They passed a porcelain filter.

(2) They increased in quantity, or multiplied, when associated, under suitable conditions, with cultures of a micro-organism that was susceptible to the particular strain used.

(3) They grew, or lived, or existed with, and at the expense of, the micro-organism, and this fact could be demonstrated by the lysis of a culture. This lysis, in some cases, might be so rapid and complete that the culture never showed sufficient growth to be visible to the naked eye, and might therefore give the appearance of an inhibitory action.

(4) When the active agent was sufficiently diluted, and was acting on visible growth of a micro-organism on a solid medium, then the action started from definite points or spots. When, also, a series of experiments was made it was found that the number of these spots diminished as the agent was further diluted. Under suitable conditions the "glassy" or clear spots increased in size.

(5) The agent could be communicated from one culture of a susceptible micro-organism to another of the same strain, in series, for an indefinite number of generations. This was equally true if the active agent was each time diluted with fluid and passed through a porcelain filter before being used.

Now, the agent described by d'Hérelle, under the name of "the bacteriophage," conforms to all of these fundamental characters. It is, therefore, a filter-passing transmissible bacteriolytic agent, and it was these agents that I described in my original paper.

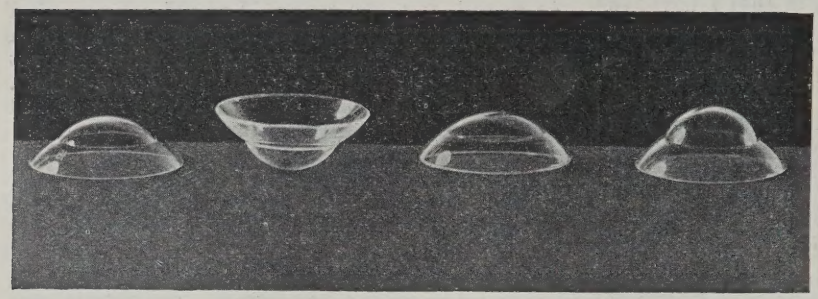
CONTACT GLASSES FOR AMETROPIA.

By A. Rugg-Gunn, M.B. Edin., F.R.C.S. Eng.,
SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL.

As the literature on this subject is still very scanty, the following notes are written to give a brief description of the glasses themselves, their uses, and the procedure adopted in prescribing them. Although the suggestion was not new even then, the Swiss ophthalmologist, Dr. A. E. Fick, in 1887 advocated contact glasses for the relief of keratoconus or conical cornea. At that time and for long afterwards the resources at the disposal of the optical manufacturer were unequal to the task of grinding glass to the necessary shape. The practical difficulties are obviously great. The shape of the glass is peculiar. It has an edge and one projecting rim which must be carefully rounded off and polished. Its curves must be optically exact. The glass is very thin and the difficulties in working the material are increased by its hardness. To produce a shell fulfilling these conditions out of a single piece of glass represents a triumph of optical achievement. In the earlier experiments of Fick and others, attention was drawn to the possibility of manufacturing glasses by blowing, and very successful results were sometimes obtained, especially by Müller of Wiesbaden. In blown-glass work, however, success in attaining the right form, even in

the hands of the most skilled craftsman, is largely in the nature of a happy accident. Occasional examples are perfect but cannot be uniformly repeated. Further, perfect optical efficiency of the outer surface is almost unattainable. Efforts were also made to mould glass into the necessary shape and materials other than glass were experimented with. It has all along been agreed that a ground glass, with surfaces based on accurate optical calculation, was the ideal, and within the past few years, largely as a result of the experiments and persistent advocacy of Geheimrat Prof. Heine of Kiel, this ideal has at last been realised by Messrs. Zeiss of Jena.

FIG. 1.



Description of the Glasses.

The modern ground glass (Fig. 1) is a thin, hollow glass bowl which fits on to the anterior part of the eyeball beneath the lids, in contact with the sclera but separated from the cornea by a fluid meniscus. It consists of a central, optically effective crown, which forms an arc of a sphere, surrounded by an optically ineffective peripheral brim, which also is spherical. The former may be called the corneal portion; the latter the sclerotic. The material is crown glass which has in sodium light a refractive index $\mu = 1{\cdot}516$, and is chemically highly resistant in order to withstand the corroding action of tears. It is well known that lacrymal secretion is destructive of glass. Artificial eyes soon become eroded.

The central or corneal part has a diameter of approximately 12 mm. and is about 0·5 mm. thick at the vertex. The diameter of the sclerotic zone (i.e., of the whole glass) is about 20 mm., and the total weight of the glass only 0·5 g. (grs. 7). It is thus easily carried by the eyeball in its movements around the centre of rotation.

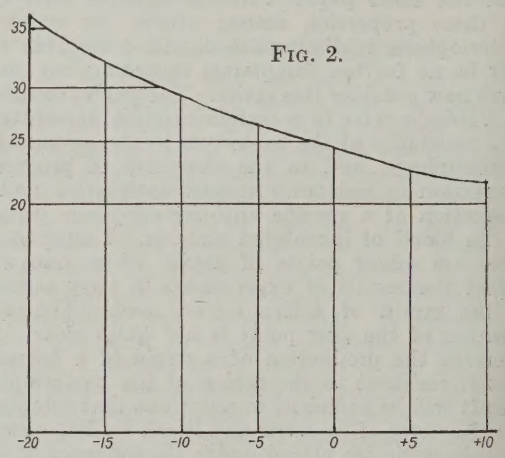
The function of the contact glass is to give a clear image of a distant object at the macula. For the correction of axial ametropia its corneal curvature, in combination with the fluid meniscus and the ocular lens system, must be designed to shift the posterior focus in eyes which vary in axial length from as low as 21 mm. to as high as 36 mm., representing all degrees of refractive error from about plus 10 D. to minus 20 D. (Fig. 2). Astigmatism need not be considered. The effect of the fluid meniscus between the cornea and the glass is that the cornea as an optical entity disappears. Except in later life, when senile changes occur in the lens, astigmatism is practically always corneal. With a contact glass, therefore, astigmatism is abolished. The problem is to select a glass by means of which the posterior focus of the combination (contact glass+fluid meniscus+ametropic ocular system) is at the fovea centralis retinæ; in other words, the posterior focus is shifted forwards for hypermetropic eyes and backwards for myopic ones.

The corneal crowns of contact test glasses have no optical power in air. The effect just described is entirely due to the fluid meniscus lying between the cornea and the inner surface of the glass. The refractive index of the cornea is approximately $\mu = 1{\cdot}376$ and that of tears approximately $\mu = 1{\cdot}336$. It follows that the fluid used should resemble tears. I have hitherto used normal saline solution (0·9 per cent.) which is almost isotonic with tears. Ridley, however, has recently drawn attention to the high protein content of tears, and I have lately experimented with other solutions which more nearly resemble his analyses. I may mention that in the earlier experiments a sugar solution was used.

Fitting and Prescribing Tests.

For the examination of the patient Messrs. Zeiss now supply a trial set of test contact glasses. The latter are arranged in series of three according to three standard scleral measurements. Each series has the same range of corneal radii—viz., from 5 to 11 mm.—representing the radius of curvature of the inner surface. The radii of the inner scleral curvatures measure 11, 12, 13 mm. respectively. These figures are etched on the rim of each glass in the trial case. Another figure which is also supplied denotes the vertex thickness of the test glass. It should be noted that the radius of the inner surface of the corneal portion is taken as the standard, as that of the outer surface varies according to the requirements of the patient. This point will be apparent later when the details of prescribing are considered.

FIG. 2.



Relation of axial length to axial ametropia.

The examination is apt to be tedious both to the patient and to the surgeon. After examining the eyes in the ordinary way, and determining the amount and character of the refraction, the process of selecting the best contact glass is begun. As several may have to be fitted and removed at each consultation, the conjunctiva must be anæsthetised. Holocaine drops (2 per cent.) are preferable to cocaine as it does not

dilate the pupil. I have, however, sometimes used 2 per cent. cocaine. A Petri dish filled with warm normal saline is convenient for handling the contact glasses. A small rubber sucker pressed on to the convex surface easily picks one up. The glass is held vertically by the attached bulb and filled with saline from a pipette. The patient leans forwards until his face is almost horizontal, and while he is in this posture the surgeon controls the eyelids with the fingers of his left hand and directs the patient to look at the glass. The contact glass containing saline must be kept level and gradually apposed to the cornea, the lids being at the same moment swept over it by the left hand and the suction bulb removed. It is not easy to control involuntary movements of the lids. When one occurs part of the fluid gets spilt and a bubble of air appears between the cornea and the glass. The bubble is a sore trial. It may recur again and again and there is nothing to be done but each time to take out the glass and start afresh. A small ivory spatula is provided for the removal of the glass. This is inserted under the rim so that the fluid drains away and the glass is allowed to drop on to a towel. During the examination, however, it is easy for an ophthalmic surgeon, who is accustomed to handling eyes, to dislocate it from its position by manœuvres of the lids.

Two separate and distinct determinations have to be made during the examination: (1) that of the most accurately fitting scleral brim; (2) that giving the necessary refractive power. To settle the first, the surgeon selects one of the three standard types of scleral measurements, and, having placed the glass in position, makes a careful examination by means of a good light and condensing lens. An accurate fit is indicated by a complete zone of adhesion near the limbus. If contact is greater at the periphery than at the limbus the rim will rub, irritate, and become intolerable. Such a glass must be rejected and one of the others tried. Good vision depends entirely on corneal curvature, but comfort depends on scleral curvature, and every effort must be made to get this right. It is even recommended that this should be done by examining the zone of contact with a slit-lamp and corneal microscope, but in my experience good focal illumination and a loupe give all the help that is required.

Having settled the matter of scleral fitting, the second problem, correction of the ametropia, remains to be considered. The particular glass to be tried first depends on the type of refractive error. For a patient with high hypermetropia, for example, one begins with a glass of small corneal curvature. Should the patient read 6/18 or better on the distant test-types, a trial frame is placed before the eyes and spheres (+ or −) added in order to decide whether vision can be still further improved. According to the result obtained other contact glasses, either with greater or less corneal curvature, are indicated, until the final result giving the best vision, with or without spherical additions, is arrived at. Where spherical additions are necessary it is important to ascertain another measurement, that between the vertex of the contact glass in situ and the back of the sphere in the trial frame. The best way to take this is with the Wessely keratometer, but there is no reason why a specially shaped millimetre scale should not be placed in actual contact with the vertex of the glass and the measurement read directly. The necessary data for writing a prescription are now available. These are: (1) the scleral radius; (2) the corneal radius; (3) the amount (in dioptres) and sign of any additional correction; and (4) the distance in mm. between the inner spherical vertex and the contact glass vertex. With regard to (3) it should be noted that the additional spheres ought not to be higher than about 4 D., otherwise the contact glass would become too heavy.

After the prescription has been dispensed the patient again attends in order to have his glass inserted by the surgeon. Most patients acquire tolerance surprisingly soon. At first he is advised to wear the glasses for a few hours only at a time, gradually lengthening the period until they can be worn all day without discomfort. They must always be removed at night.

Advantages.

This is not the place to discuss fully the advantages of contact glasses over spectacles, especially the optical considerations involved, but one or two points may be alluded to. Perhaps it may seem a disadvantage that for presbyopic patients a pair of reading spectacles is still necessary, but, as the strength of the reading correction need hardly ever be more than 2·5 D., a very light pair is all that is required. A consideration that is perhaps not so important now as formerly is that contact glasses are practically invisible. There are still circumstances, however, when this is desirable. The ametrope, especially the myope, has restored to him a full field of vision and full range of movement. The retinal image of the myope is magnified, up to 50 per cent. in some cases; that of the hypermetrope is much less influenced. This fact is susceptible of optical proof, but it is sufficient now to state that an enlarged image is a property of a long focus, such as the addition of a contact glass must of necessity confer. It assumes importance also in cases of anisometropia. It should be stated that contact glasses are not suitable for the treatment of squint. Perhaps their greatest value is in cases of corneal haze or irregular astigmatism, including conical cornea, which cannot be helped at all, or only to a slight extent, by ordinary glasses.

While the use of contact glasses and their possibilities cannot yet be said to have been fully explored, my brief experience has already convinced me that they have come to stay, and that in the future they will be found to constitute a very important addition to the methods now available for conserving and treating defects of vision.

DONATIONS AND BEQUESTS.—Miss Alice Jane Davis, J.P., Belhaven-terrace, Kelvinside, Glasgow, left £2000 to the Western Infirmary, £1000 to the Royal Infirmary, and £500 to the Hazlewood House for Retired and Aged Nurses.—Alderman John William Turner, of Staincliffe, Batley, gave everything to his wife for life, and then £1000 to the Batley and District Hospital.—Over £20,000 will pass to charitable objects under the will of Miss Grace Lamb, of Bowdon, Cheshire, who left £48,570. Subject to various legacies she gave the residue of her property, about £20,000, between the Manchester Infirmary, the Altrincham Hospital, and the Prisoners' Aid Society, Manchester. She also appointed her one-tenth share of certain settlement funds to Ancoats Hospital, Manchester.—The Ingham Infirmary, South Shields, has received a cheque for £1000 from Mrs. C. W. Taylor, of Westoe Village, to endow a bed in memory of her son, Lieut.-Commander C. R. R. Taylor.

CLINICAL AND LABORATORY NOTES

CAUTERISATION OF ADHESIONS

IN TREATMENT OF BRONCHIECTASIS BY ARTIFICIAL PNEUMOTHORAX.

BY A. J. SCOTT PINCHIN, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK;

AND

H. V. MORLOCK, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS AT THE HOSPITAL.

THE intrathoracic cauterisation of adhesions which are preventing the complete collapse of the lung is now a well-recognised procedure in the treatment of pulmonary tuberculosis by artificial pneumothorax.

Although artificial pneumothorax has been used as a therapeutic measure in some cases of bronchiectasis, we have been unable to find any records in the literature of the cauterisation of adhesions, which may be preventing complete collapse, in cases of bronchiectasis. We have had under our care two cases in which complete collapse was prevented by adhesions to the parietal pleura, and in which it seemed justifiable to attempt to obtain a complete collapse by division of the adhesions.

The procedure used in the cauterisation was that suggested by Maurer—i.e., enucleation of the adhesion at its parietal end; as the danger of infecting the pleura is more real in this disease than in tuberculosis, it is essential to use this method.

It is necessary to anæsthetise the pleura. For these two cases the Davidson one-way instrument was used. Although in the Chandler-Schranz instrument a special injectoscope has been devised, this necessitates another somewhat expensive appliance, and we have found our method quite satisfactory in practice when this instrument has not been available. Having localised the adhesion previously by X ray examination the instrument is introduced at right angles to the parietal end at what one judges to be 4 or 5 inches distant from it.

The probable site of the base of the adhesion under the external chest wall is judged by any one or a combination of three methods:—

(1) The instrument is advanced until it is as near to the base of the adhesion as possible, and from without the point of maximum light seen through the chest wall is marked on the skin overlying this area; as the light is diffused this method is not very accurate.

(2) The base of the adhesion is viewed through the instrument and, taking into consideration the angle of vision of the particular instrument, a finger is placed on the external wall of the chest at the judged insertion of the adhesion; this point is marked.

(3) The instrument is introduced until it touches the adhesion, and the straight line which it would make if continued through the chest wall is noted and marked.

The base of the adhesion having been thus localised on the external chest wall, a long stout hypodermic needle attached to a syringe containing 2 per cent. novocain is introduced through the nearest intercostal space and watched through the thoracoscope as it enters the pleura. With this method we have been successful in striking the base of adhesions only a few millimetres in diameter on the first trial; if, however, the point of the needle is a centimetre away it can usually be made to reach the base of the adhesion through the same skin opening. If the adhesion is not accessible directly, being under the scapula, a long needle such as may be used for splanchnic anæsthesia may be introduced from the side of the chest opposite to the adhesion and guided into the adhesion from the intrathoracic side. Successful collapse was obtained in both cases recorded.

CASE 1.—A female, aged 13, had had bronchiectasis of the left lower lobe since the age of 6, following a pneumonia. Artificial pneumothorax was induced on Oct. 4th, 1929. A skiagram on April 8th, 1930, showed the upper lobe completely collapsed and the lower lobe partly collapsed but held up by adhesion running from its upper part to the parietal pleura in the region of the fourth rib posteriorly. Cauterisation was performed on May 10th. A skiagram taken the next day showed division of the adhesion and further collapse of the lower lobe. The subsequent progress was satisfactory.

CASE 2.—A female, aged 11, had very extensive bronchiectasis on the left, diagnosed in 1925, when she was admitted to Victoria Park Hospital with a view to artificial pneumothorax. In consultation with our colleague, the late Dr. Clive Riviere, the idea was abandoned for fear of infection of the pleura; at that time artificial pneumothorax was not regarded favourably in bronchiectasis. In January, 1929, Mr. George Waugh (Hampstead General Hospital) performed a phrenic avulsion in an endeavour to ameliorate the condition. Some improvement followed. In December, 1929, the child started to have profuse hæmoptysis, and was admitted to Victoria Park Hospital with the idea of a thoracoplasty. Artificial pneumothorax was first attempted, and—very unexpectedly—was successful in producing a good collapse except for one wide adhesion. This adhesion was successfully divided, and a complete collapse was obtained. The hæmorrhage ceased and the child's general condition improved.

The cauterisation of adhesions in artificial pneumothorax induced for the treatment of bronchiectasis appears to be as successful in producing a collapse of the affected lung as it is in most cases of pulmonary tuberculosis.

PULMONARY EMBOLISM IN AN INFANT

FOLLOWING AURAL INFECTION.

BY J. ARNOLD JONES, O.B.E., F.R.C.S. EDIN.,
SURGEON, EAR, NOSE, AND THROAT DEPARTMENT, ROYAL MANCHESTER CHILDREN'S HOSPITAL.

THE extreme rarity of pulmonary embolism in childhood makes the following case worthy of record.

A female infant, 7 months old, was admitted under my care in hospital on April 30th, 1930. When 3 months old she had had pneumonia, after which both ears had started to run. On April 20th she seemed to have pain in the left ear and the discharge lessened. On April 27th a swelling appeared behind the left ear and gradually increased. On examination a typical acute mastoid abscess was observed on the left side. The right ear was also discharging. The heart and lungs were examined and no abnormality was found.

On May 1st a Schwartze operation was performed. The next eight days were uneventful, the infant apparently making excellent progress, while the local condition was entirely satisfactory. On May 9th at 2.30 A.M. the resident surgical officer was hurriedly summoned to see the infant, whom he found cyanosed and with very rapid respirations. The onset was quite sudden, the child having been apparently quite well a few minutes before. Oxygen was given through nasal catheters and camphor was injected. Death occurred at 6.30 A.M.

Permission was given for a modified post-mortem examination which did not allow the skull to be opened. This was performed by the resident surgical officer, Mr. Peake. Old clot, rounded, was found blocking the branches of

the pulmonary artery to both lower lobes and right middle lobe. There was no pneumonia, but these lobes were collapsed. Emphysema of the upper lobes was present. The heart was normal. Unfortunately the condition of the ears and lateral sinuses could not be discovered.

There are 11 recorded cases of pulmonary embolism in childhood, 8 of which were due to aural infection. In 1905 Pehu and Horand reported a case in a child of 6 years. A similar case was recorded by Guillemot in 1906, and in 1913 Lutz reported six cases. The remaining three were due to other causes.

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON.

At a meeting of this Society on Nov. 10th, with Dr. R. A. YOUNG, the President, in the chair, Prof. CHEVALIER JACKSON (Philadelphia) opened a discussion on the diagnosis and treatment of

Malignant Disease of the Lung.

Many misgivings beset him, he said, when he contemplated taking part in this discussion. The bronchoscopist lacked the viewpoint of the internist and the surgeon, and this prevented him from having a comprehensive outlook on such a subject. However, clinical experience was clinical experience always, and facts were facts. Experience was that which was gained while looking for something else, and this was true for cancer of the lung.

Prof. Jackson's address consisted in the exhibition and explanation of photographs and radiograms of cases, with brief histories and results. Usually, he said, lymphoma was not regarded as malignant growth, and yet some of his cases of lymphoma presented many of the characteristics of malignant disease. He had had 14 or 15 cases of malignant disease associated with foreign body. A slide shown was that of a man who had cancer in the right lower lobe of the lung and also a tooth in the lung. A woman came to the radiologist with a pin in the lung and she died of hæmorrhage. The autopsy revealed a large cancer involving the right lower lobe in the same region as that in which the pin was found. That might not be more than a coincidence. Another patient came with advanced asthma; bronchoscopy was asked for, and a fungating granuloma was found which appeared to be in the trachea. It turned out to be epithelioma. Another was a man who had been spitting up pus for three years, and was having rises of temperature, but he was said never to have spat up blood. The radiologist suspected malignant disease in the left upper lobe. Bronchoscopy revealed a fungating, bleeding, oozing lesion, and histological examination showed it to be cancer. Another patient had been spitting up blood ten years, and he was thought to have a pulmonary abscess by the radiologist who saw him first. Later examination with X rays gave rise to the suspicion of malignant disease, for he was having fever of the intermittent septic type, and was spitting up quantities of foul pus. Bronchoscopy showed there was a cancer in the right main bronchus. Another man had had a cough 20 years, and a fungating lesion was found which had epithelialised; it was not bleeding, but was a nodule which could be nipped off. It proved to be carcinoma.

Prof. Jackson showed photographs of a case of atelectasis of the right lower lobe. Occasionally, he said, atelectasis would light up quickly. If atelectasis occurred slowly it might be due to absorption of air by the circulating blood, but when it was suddenly produced he believed it was due to a check-valve action pumping air out of the lung. In one such case he found a nodular fungating lesion, a floating tumour in the bronchus. He excised it, thinking it was a fibroma, 16 years ago. It was endothelioma, and it never recurred.

The treatment of cancer of the œsophagus by deep X ray therapy had been very disappointing in comparison with treatment of the lung. The mortality of cancer of the œsophagus still remained at 100 per cent. when treated with deep X ray therapy. The experience at his clinic had been that there were some malignant growths in the lung of a very low grade of malignancy, and which were quite sensitive to X rays and amenable to that treatment. Whatever might be said about lobectomy, it could be stated that it had never had a fair chance for a test, because cancer of the lung was almost never diagnosed early. It would always be recognised late until every patient suspected of pulmonary tuberculosis was examined with the bronchoscope. A very important sign in the diagnosis of malignant disease of the lung was a wheeze heard at the patient's open mouth; it was not heard at the chest wall. At his suggestion those at the clinic had adopted the maxim "all is not asthma that wheezes."

After showing a cinematograph film illustrating methods of examination and the appearances seen through the bronchoscope, Prof. Jackson said he was not an enthusiast about radium and radon seeds in cancer of the lung. Until more was known of ætiology of cancer and methods of treating it, lobectomy and radiology should receive special attention. It was a platitude in the profession that diagnosis of cancer should be made early, but it was not so well known that the bronchoscope should be used early; he did not know any other way of making an early diagnosis of cancer of the lung.

DISCUSSION.

Mr. V. E. NEGUS pointed out that in only a small percentage of cases of bronchoscopy was the reason the presence of a foreign body. Of 200 bronchoscopies he had performed, only five were for foreign body, the remainder being for other causes. To do this work with success a good deal of attention to small details was required, and that was one of the secrets of Prof. Jackson's great reputation, both as an operator and a teacher. It had been said that a drawback to a more general use of bronchoscopy was the difficulty of getting trained assistants, but this was only a partial difficulty if care was taken in the teaching; even at hospital, with a change of assistants and nurses every six months, it was possible to get success and he used local anæsthesia. Many thought bronchoscopy was unsuitable because a general anæsthetic was needed; not only was it unnecessary, but a patient with carcinoma of the lung was not a suitable

subject for a general anæsthetic. He used morphia and scopolamine. He exhibited a glass bronchoscopic shield which he had had made, in order to protect the face of the observer from the coughing up of discharges. When one part of the shield was befogged by the patient's expectoration a clear part could be turned and the observation continued.

Dr. J. F. BRAILSFORD showed pictures of a case in which bronchoscopy would not be of much use. There was a dense shadow, which very slowly increased in size, and no diagnosis could be arrived at. The patient had a temperature, and there was pain over the area; a needle inserted failed to withdraw anything. In the later stages growth was suspected, and eventually it was found to be sarcoma of the rib.

Mr. HERBERT TILLEY said that one of the main points in the opening address was that many lesions which clinically appeared to be of the ordinary type turned out to be malignant, and he showed slides of a case in which the symptoms suggested malignancy but it turned out to be benign. The man was gassed in March, 1918, and his symptoms dated from the gassing. In the October following he began to suffer from hæmoptysis, and later he had stridor and expectoration, with dyspnoea. The stridor was marked, and he had impaired respiration. X rays showed an infiltration round the right bronchus. In the consulting room the stridor and distress were very noticeable, and he was taken into a home and the tumour which was seen by radioscopy was removed. It was projecting into the trachea, and there was a complete check-valve action. It proved to be a papillary granuloma. Usually it was found that a supposedly benign growth turned out to be malignant, but in this instance it was the reverse.

Mr. H. P. NELSON pointed out the importance of irradiating the glands, and explained his investigations with this object. On the cadaver he was able to push radon seeds through the bronchial wall into the glands. Radon seeds could not be got into the hila, for that would mean too great a displacement of trachea and bronchi. He had succeeded in introducing radon seeds by means of a diathermy current of low amperage, and with very little bleeding.

Mr. J. E. H. ROBERTS said he felt that surgical removal was not, and never would be, of much use in the majority of cases of carcinoma of bronchus or lung. The future, in his opinion, lay in irradiation, by X rays, radium, and radon. He showed an apparatus by which a number of radon seeds could be propelled into a growth from the handle of the machine. The problem of inserting radon seeds into the lung through an open thoracotomy was not a simple one, for in a large number of cases infection was already present in the pulmonary airways; and if the lung was to be punctured through an open thoracotomy wound, there was grave danger of causing pyothorax, which in such a patient might rapidly cause death. He felt that the mode of use of radon seeds into malignant growths had long been haphazard; instead of the few seeds used as a rule, there should be a dozen, perhaps two dozen.

Mr. TUDOR EDWARDS said there appeared to be two types of growth which arose in the lung. A good deal had been heard about the primary bronchial growth, but there was another type, a rarer one, arising in the periphery of the lung. Two months ago, in a paper he read at Winnipeg, he recorded 116 cases of growths of the lung itself which he had seen, and only eight of them arose in the peripheral parts of the lung. In three he attempted removal of the growth. One was an epithelioma, and it recurred in three months; he did a partial lobectomy of the lower lobe. Both the others were endotheliomata. One died owing to a technical operation error, and the other was operated upon two years ago, having the lower lobe removed, and he was alive and well to-day. Now and again one encountered a secondary growth which justified removal, but usually secondary deposits were multiple. There was a smaller probability of being able to successfully remove bronchial new growths; they arose from near the main bronchi, and that meant requiring a complete pneumectomy, which was impossible. Still, he removed in January last a growth which seemed central to the bronchus, a columnar-celled carcinoma the size of a walnut, and the patient survived and was, he believed, alive to-day. He had been disappointed with the results of X ray treatment of pulmonary growths, for they did not seem to react well to the rays. He showed an instrument, consisting of a double tube, for the introduction of radon seeds, capable of holding two dozen seeds, and the seeds could be introduced through the bronchoscope. Its object was to keep the lumen open and prevent the stagnation which was a factor in keeping the patient somewhat ill. He had kept such a tube in situ for six and a half days, and he thought this time could be extended.

Dr. G. VILVANDRÉ thought that some 90 per cent. of the growths in the lung visible by X rays were carcinomatous, and obviously were such as were difficult of removal. He described a case in which he was able to prove that each radon seed had a marked influence on the surrounding tissue only to the extent of 1 cm., thus supporting the contention of those who advocated many seeds, so as to ensure every part of the growth being irradiated. He did not think carcinoma of the lung would be diagnosed in the X ray room, nor did he think the bronchoscopist could diagnose many of the early cases; these must be recognised by the general practitioner, who should be taught the early signs.

The PRESIDENT felt that this type of case was met with nowadays more frequently than could be accounted for by more precise methods of diagnosis. He did not think enough use was yet made of radiography, lipiodol, and bronchoscopy. He agreed that lobectomy was the method of choice for some of the small localised growths away from the hila, but unfortunately these growths were not recognised until secondary growths had occurred in the neighbourhood of the hila.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

AT the opening meeting of this Section on Nov. 5th the new President, Mr. CHARLES H. FAGGE, took the the chair and delivered an address on the

Aims and Limitations of Modern Surgery.

No one, he said, could have had charge of patients for 30 years, as he had, without occasionally asking himself whether his ideals had been achieved. Happy was the surgeon who could claim, as many no doubt could, that his aim was still to the infinities of the heavens. The philosophic surgeon, however, would confess that his ideal was still unaccomplished, for his aim was restoration to the normal, both as to organism and tissue. It seemed a pity that so much time and energy were taken up in attempting to prolong the life of patients suffering from terminal states, for whom the surgeon's efforts can do no more than leave them in a condition far from normal. Far too much

of modern surgery was mutilation. Excluding correction of injuries, such as fractures, and cosmetic operations, such as those for cleft palate and hare-lip, there was little in surgical technique which did not replace one evil by another. That fascinating field which sought to combat the ravages of age by transplanting an organ, or part of an organ, from an ape closely allied to man, or to replace a damaged or diseased organ by a similar organ taken from another human being, or to graft a finger where one had been missing, was still in its infancy. Much in this domain could not bear the test of results. Such transplantations could only succeed when the technique of connecting the blood-vessels and lymphatics of the transplated viscus to those of the host had been improved so far that the nutritive fluids could immediately be set going.

What, said Mr. Fagge, were the physical limitations placed in the surgeon's way? Apart from those engendered by the morbid state of the patient, there were the limitations resulting from the nature of bodily tissues and from the healing of every operation wound. There was, no doubt, truth in Lord Moynihan's remark that surgery as a craft had now reached finality, but it was not new; Erichsen had made it when Listerism first became firmly established. Even with the best technique and most accurate primary union a scar resulted. The width of a scar, though of no importance in coarser tissues, was an absolute bar to function in highly specialised glands, and blocked the transmission of impulses in any part of the nervous system. Modern aseptic technique had modified the amount of scar tissue formed by limiting the leucocytic infiltration, but if he was right in believing that proliferation of fixed connective tissue cells was the ultimate factor in causing fibrous tissue to form he could see no means of controlling it.

What happened, he asked, to any one of the higher connective tissues when it was subjected to an abnormal strain? In a patient who had undergone a radical cure by Bassini's method for inguinal hernia the appearance of the conjoined tendon was familiar. Normally, this formed a robust muscular upper border to the inguinal canal, which by its contraction was closed at the upper end, so forming a sphincter to the internal abdominal ring when the abdominal wall muscles were put into action. But when sutured down to the inguinal ligament one of two results ensued: either the stitches cut out or the mass of muscles degenerated to form a thin fibrous barrier. This might be a sufficient protection against recurrence, but its function was now no more than mechanical and its structure was greatly changed. Human tissues were intolerant of abnormal tension. A strain applied to soft parts usually resulted in suture material, whatever its nature or strength, cutting through; there was a giving way of the structure which it was intended to hold down, or a scar was formed by degeneration of the tissues held down. This limitation applied to many so-called pexies. In operations for incisional or ventral hernia where a scar area had been produced by infection, and the fibrous tissue over it offered but feeble resistance to normal abdominal tension, the surgeon's object was to replace the scar by normal resilient muscular layers. Much ingenuity had been expended in attempting to close this defect, yet most devices did no more than replace a thin weak scar by a thicker and more resistant one; such was the result of introducing metal filligrees or living suture material like fascia lata. Attention should be paid, Mr. Fagge suggested, not to the gap, but rather to the tissue which filled it, and to the free excision of all abnormal fibrous tissue in the scar. When this had been done, normal aponeurosis and normal muscle could be approximated, each to each, and the layers of the abdominal wall sutured one by one. He had not met with a case of incisional or ventral hernia which he could not close in this way with ordinary catgut sutures; they were all now following their ordinary occupations. An eccentricity of scar formation was traumatic keloid, but probably if this was freely excised it would not re-form.

DISCUSSION.

Mr. MAX PAGE thought the President was a little unjust to his department when he suggested that, with the exception of face-lifting and so forth, surgery was a mutilating procedure. In treating ventral hernia when a large gap was left his habit was to carry out a plastic operation, generally without the employment of any foreign material. He had attempted to get apposition of the main bulk of the abdominal wall by an overlap, such as was practised in the Mayo operation for umbilical hernia. Many cases during the war in which there was gross loss of tissue had been treated on these lines with good results. He was interested to hear that keloids could be excised and a good scar result; his own view had been that if a keloid was excised another appeared in its place. He would have liked to hear a reference to the treatment of infective processes; the older the surgeon the more he was inclined to leave infection alone and simply to avoid tension.

Mr. ZACHARY COPE suggested that the surgeon limited himself by the multiplication of specialties. But there could be no limit to surgery; if it was to live it must advance, and first of all in the direction of intelligent coöperation between surgeon and physician. Such advance might result in the avoidance of operation; in the next ten years, for instance, a medical cure might be found for exophthalmic goitre, which was a toxic process. Gastric ulcer also should be curable without operation. In some parts of the body the eradication of disease by radium left no scar which could be seen. Many keloids vanished under the influence of X rays; certainly they became softer.

Mr. A. J. WALTON agreed that the chief aim and object of the surgeon of the future would be the abolition of surgery. Practically all surgical operations were mutilating; he had always laid down a rule that as little normal tissue should be removed as possible. Mr. Cope was right in his reference to exophthalmic goitre; at present surgery was the only certain method of cure, but he could not envisage the surgeon being associated for long with such a mutilating operation. The continental method of removing half a stomach for a small ulcer was wrong in theory. In his own practice he found himself doing more medicine and less surgery. The surgery which approached nearest to the ideal, in restoring normal function, was the removal of benign tumours. Other instances were fractures and wounds of normal tissue, in which structure and function could be restored with the minimum of scar tissue. There was, he thought, no condition in which the surgeon felt so helpless as in infective processes. For himself he was coming to the view that extensive surgical procedures for the treatment of sepsis were wrong; it was now his custom to wait until the sepsis became localised and then to deal with the focus. He had seen in recent times far fewer instances of widespread operation for cellulitis.

Dr. N. L. LLOYD spoke of the variations sometimes seen in patients suffering from congenital abnormalities, such as children who had just escaped hare-lip.

All surgeons had seen cases of the kind in which nature had produced scars such as the surgeon strove in vain to emulate; why, he asked, was this so? Every face was, in fact, made up of a series of marvellously sutured seams. He had been struck by the occasional occurrence of keloid in an inguinal incision; his impression was that it occurred more frequently at the lower end of the hernial scar than at the upper, but it was a matter of conjecture whether that was due to encroaching on the area of the pubic hair, especially as in the case of children the growth of hair in that region was a matter for the future. He had excised keloids and seen them recur. The proper treatment of keloid was, he thought, to excise it and then apply radium. Some children seemed specially prone to keloid formation.

Mr. JULIAN TAYLOR said that any surgeon who had attempted to operate on a case of strangulated hernia between a filigree would hesitate to use this method. It was, he thought, very rare for a hernia of the abdomen to be due to a nerve injury; most abdominal injuries were within the linea semilunaris and the only muscle which could be paralysed was the rectus. It was a different matter in old war injuries, in which all the nerves in the area might have been destroyed, almost on their emergence from the lumbar spine.

Mr. HUGH LETT did not think that surgery was in such a bad way as had been inferred. In speaking of mutilating operations one had to consider on what kind of patients they were performed. A gall-bladder might be so hopelessly diseased as to result in a general poisoning of the patient; and if the surgeon could remove it and restore that patient to perfect health the "mutilation" was surely justified. Plastic surgery had brought about extraordinary improvements. Resection of parts of the bladder, and perhaps of the ureter, for deadly disease rendered patients practically as well as they were before. Had the title of the address been extended to include the aims and limitations of surgeons, as well as of surgery, an amusing as well as an interesting discussion might have ensued. He related the case of a man of 62 whose penis he had removed for carcinoma 14 years ago, and who was told to return in about three months to have the glands removed. He failed to do so, but returned recently because he had hydrocele. Limitations were sometimes imposed on the surgeon by the patient, who might, as in this instance, score heavily.

REPLY.

The PRESIDENT remarked that each surgeon must find out his own limitations; he should learn what he could and what he could not do. It was surely better to do an operation he knew he could accomplish than another which someone else had advised. Acute infections he did not regard as part of his text. He had never had to deal with a hernia due to paralysis of muscle. In cases of abdominal hernia he relied on spinal anæsthesia.

UNITED SERVICES SECTION.

AT a meeting of this Section, held on Nov. 10th, Surgeon Captain S. F. DUDLEY, the President, took the chair, and Group Captain MARTIN FLACK read a paper on

Air-sickness and Sea-sickness.

He said that air-sickness and sea-sickness had certain factors in common, and differed in the relative importance of these factors. The data concerning air-sickness were based largely on opinion, and statistics were still badly needed. Nevertheless, he had come to the conclusion that the great cause of air-sickness—apart from anticipatory anxiety, which was difficult to estimate—was defective ventilation. Pilots who had never been sick in open machines suffered as soon as they flew in cabin machines. The problem of ventilation was very troublesome. An aeroplane ventilated from back to front, and the cabin tended to be stuffy in some parts and cold in others. An open window did not cool the person who opened it, but made a draught on the back of the neck of the person sitting immediately in front. If a passenger vomited in front, those behind all saw his sufferings; if he vomited at the back the smell was conveyed all through the cabin. It was important that the foot level be warmer than the head level, or the passengers would feel stuffiness. Research was being undertaken with the katathermometer, and it was hoped that this work would soon bear fruit.

The factor of undue stimulation or supersensitiveness of the vestibular apparatus weighed less in the air than at sea, for the air was smoother and the amount of disturbance to the semicircular canal smaller. Persons who were sea-sick were not necessarily air-sick; if this fact could be brought to the public notice it would lessen the importance of anticipatory anxiety, and popularise flying. The lack of agreement between visual, labyrinthine, and deep muscle sensations was important in the air, and to reduce it passengers must have a wide view of the horizon through good windows. This was one of the chief reasons why the high-wing monoplane was one of the most comfortable machines in which to travel; the passenger's view was not intermittently interrupted by moving struts and wires. It was also necessary to increase the amenities within the cabin. Vomit receptacles must be hidden from the public eye, and the passenger's interest directed to booklets or maps rather than to ominous paper bags or the agonies of their fellows. Persons handicapped by supersensitiveness of the semicircular canals were eliminated from among would-be pilots by their reaction to rotation in a chair. Those liable to become dizzy in the air had a marked rise of blood pressure and disturbance of ocular muscle balance, although their nystagmus time might be normal. Another group who complained of giddiness actually tended to faint; they manifested a fall in diastolic pressure. Candidates who suffered from anticipatory anxiety showed a rise in blood pressure when placed in the chair, even before it began to rotate.

SEA-SICKNESS.

Group Captain Flack described the results of tests which he had carried out in liners. There was a small group of passengers who had a supersensitive labyrinth and who would be sea-sick at any uneven movement. The mechanism seemed to be merely a stimulation of the vagus, which caused contraction of the stomach and vomiting. In most sufferers some additional factor was necessary. The sensory dilemma played an important part: people did not like their eyes to tell them that the ship was coming down while their labyrinth told them that it was going up and the deep muscles gave them some other information. Persons who had acquired their "sea-legs" tended to correct the dilemma by movement of the head. This factor was probably aggravated by the induction or increase of ocular muscle imbalance. Members of a crew who had never been sick for 20 years or more had all been found to possess good ocular muscle balance

Imbalance was measured by the Bishop Harman diaphragm, and tests had shown that it was increased during the period of nausea, whether the eyes were open or shut. It might be an effect of the uneven movement and not a cause; it was brought about by reflex action from the semicircular canals and the eye or neck muscles. One of the symptoms was disinclination to continue reading.

Physical factors, such as stuffiness and smells, were undoubtedly important to a number of people, especially when combined with anticipatory nervous anxiety. The general health and time of exposure also played their part. The phenomena of acidosis and acetonuria required investigation, and it was necessary to differentiate between the afferent stimuli and the resulting impulses. These changes in the blood chemistry were an effect and not a cause. Some persons who suffered from severe sea-sickness were really in a state of semi-starvation. Many persons, even if they had no tendency to dyspepsia, were not in a fit state to withstand uneven movement, especially those who had drunk too much alcohol the night before. The effects of sea-sickness might be confused with those of alcohol. Poverty of abdominal tone might predispose, and some patients—especially those with slack abdominal walls—staved off sickness by wearing abdominal belts.

In conclusion, Group Captain Flack said that each case needed close examination before the right treatment could be prescribed. A "blunderbuss" must contain a drug which would prevent the afferent impulses from reaching the centres; a large dose of alkali might be useful, and the mixture might be made palatable with sugar.

The PRESIDENT suggested that the ventilation problem in aeroplanes might be solved by mechanical ventilation. In his experience, a fit and athletic man with plenty of tone was less likely to be sea-sick than a person of inferior physique. Alcoholic excess was not important; alcohol actually relieved the condition, either by inhibiting stimuli or by destroying the sense of position in space and of movement of the ship.

Surgeon Vice-Admiral ARTHUR GASKELL remarked that some persons obtained protection from sea-sickness by tying a horse's girth tightly round the waist. He asked whether ocular muscle imbalance was not purely a concomitant of vomiting.

AN ŒSOPHAGEAL FACTOR.

Dr. E. P. POULTON doubted whether the labyrinth was as important as Group Captain Flack suggested. Stimulation of the labyrinth ought to cause nystagmus, but this had never been observed by G. H. Oriel. The connexion of the labyrinth with sea-sickness had been supposed from the phenomenon of Ménière's disease, but the most striking symptom of this was vertigo, of which few sea-sick persons complained. From observations he had made on a student he had discovered that nausea was associated with an extreme relaxation of the œsophagus; he suggested that it was identical with, or preliminary to, œsophageal pain. In ordinary contraction of the muscle the one took pressure off the end-organs, but when tone was relaxed the pressure reached them. Swing tests had shown that nausea was felt either just before or just after the dead centre on each side—i.e., on a movement tending to elongate the œsophagus. It was considerably less severe after dinner. This theory explained the relief the patient felt when he lay down, and the greater severity of a pitch than a roll. Nausea was not the only effect; he had himself felt a tightness in the head, and suggested that congestion of cerebro-spinal fluid upwards might be considered in this connexion. He agreed that the chemical changes were secondary.

Wing Commander F. N. SMARTT complained that Group Captain Flack had dealt chiefly with secondary causes. He did not agree that stuffiness was a basic cause of air-sickness; bumping would cause sickness whatever the conditions of ventilation. Sickness in the air or at sea was due to a splanchnic defect, which caused a definite sensation of loss of equilibrium. This might possibly be felt through the eyes, semicircular canals, or splanchnic area. An air pilot was only made sick by severe bumping, this being the one sensation which he could not anticipate. The spinning test was imperfect, for it involved no disturbance of equilibrium. Movements which induced nystagmus would hardly ever induce sickness in persons who had no splanchnic defect. Vibrational noise was an important contributory cause in the air.

Dr. HUGH STANNUS suggested that the sickness of sea and air was identical with that of a stuffy room, and that the effect on the semicircular canals was not necessarily a primary factor. He asked whether Group Captain Flack had noticed any signs of a diathesis in the histories of his subjects, and whether, acetonuria might not be the result of anticipation. Sea-sickness was often associated with diarrhœa.

Surgeon Commander G. H. HAYES differentiated between patients who recovered immediately and those who were prostrated; he asked the reason for the difference between these types.

Fleet Surgeon W. E. HOME did not regard ocular muscle imbalance as very important; he himself possessed only monocular vision, but was often sick. If sea-sickness were due to splanchnic imbalance patients would not become immune so quickly.

Group Captain FLACK briefly replied.

SECTION OF PSYCHIATRY.

AT a meeting of this Section, held on Nov. 11th Dr. S. A. KINNIER WILSON delivered his presidential address on the

Approach to the Study of Hysteria.

Hysteria, he said, had not yet yielded its secret. The period of psychological study had been marked by a lack of objective and empirical research. The outstanding feature of hysteria was, perhaps, the changes which its clinical syndromes had undergone. Religious stigmata and impersonations of great actresses were out of date; as was the simulated spinal disease which had been outstanding in the early part of the eighteenth century. The phases had corresponded with contemporary medical predilections; the hysteric had done her best to adapt to the calls made on her. To-day we sought the clue in the psyche, and the hysteric found her somatic manifestations at a discount. Nevertheless, the kaleidoscopic patterns of hysteria were composed of unaltering instinctive and impulsive reactions, and an earthquake or a world war would lay bare manifestations resembling the classical ones. Hysteria might be but a name for a reaction, capable of being expressed in dynamic neurophysiological terms. How were the disturbances of function actually brought into being? Could anything be learnt of the seat of the functional defect? Organic disease would teach more about hysteria than vice versa. Physiological investigation needed no apology, but few psychologists had pursued it.

CLINICAL FEATURES OF HYSTERIA.

Defective inhibition of the antagonists was a pathognomonic sign of the utmost value. A paraplegic asked to extend the legs would first show contraction of the hamstrings. This was a disorder of the Sherringtonian law of reciprocal innervation. In the "organic" condition of athetosis and in some frontal lobe conditions a similar derangement of this law might be seen, and the conclusion was, therefore, that hysterical palsies bore the physiological imprint of cortical defect of function. Another valuable sign was the "shunting sign," in which the innervation was shunted to another group. If the patient was asked to grip a finger the grip was absurdly weak, but the biceps or deltoid might be in powerful contraction. This also might be found in some organic conditions. Both could be imitated voluntarily, but this did not therefore indicate simulation. "Voluntary" detonisation might proceed so far as to cause loss of knee-jerks, and a fair reproduction of Jacksonian epilepsy could also be given "voluntarily." The criterion of imitational capability was worth nothing. The point was that imitability characterised motor phenomena, of which the seat was cortical. Both "shunting" and "antagonist contraction" signs indicated impairment of cortical function coupled with defective inhibition.

Hysterical tremor presented no distinctive features from those of "organic" tremors; typical "intention tremor" was seen in hysterical cases, and "organic" tremors were affected by numerous psychic factors sometimes supposed to affect hysterical tremors only. Fluidity of organic tremors was so pronounced as to render any such distinction valueless. Patients with hysterical tremors were supposed to suffer less from fatigue than normal persons imitating tremors, but as long as the tremor was kept up, it might be indistinguishable from an "organic" one. In hysteria, as in organic states, tremor was an escape phenomenon of an infracortical level.

Hysterical fits, ranging from fugues to immobility, were hard to synthesise, but were one and all escapes from conscious control. Clinical differences between hysterical and other convulsions stood for modifications in site and extent, but not for intrinsically different processes. The hysteric might simulate decerebrate rigidity. If the hysterical process removed the action of the cortex it was hard to see how the patient could adopt any other attitude. The anæsthesias of hysteria were supposed to correspond with psychological and not with physiological disposition, but in syringomyelia there might be glove and stocking anæsthesia; in parietal lobe lesions there might be sensory changes in hand and leg, and "organic" disease might involve loss of sensibility over the front of the body and not over the back. These types, therefore, were not specific for hysteria. Absence of bleeding on pin-prick had been seen in thrombosis of the cerebellar vessels. Bulbar centres and mechanisms might thus be involved in hysteria.

Reflectivity was often abnormal in hysteria; the plantar response might be lost, the abdominal reflex weakened or lost, and ankle-clonus or sphincteric trouble might be found. These phenomena must bear the same interpretation as in "organic" lesions.

CONCLUSION.

Cortical, infracortical, mesencephalic bulbar, spinal, and neurosympathetic mechanisms might be disordered in function as a result of processes called hysterical. Differentiating criteria between "organic" and "hysterial" conditions had lost much of their specificity. In one of its respects, at least, the condition became less mysterious when its processes could be traced through various physiological levels. The terms of opposites "organic" and "functional," "structural" and "nutritional," should be abandoned, but "dynamic" and "static" could be used. Hysteria showed a prominence of dynamic and a comparative absence of static elements. Rapid cure was to be explained on the hypothesis that function was abrogated dynamically and not statically. A strictly sexual ætiology was not universally applicable. On the view that hysterical manifestations were simply reactions to stimuli it was still hard to understand why these restricted stimuli should be capable of causing responses varying from fugue to retention of urine. There was a glaring hiatus. Emotional states could be taken as exciting if not predisposing causes, but individual hysterical reactions were not easily correlated with such a general excitant as emotion. In many cases it seemed impossible to associate the part of the body affected with some emotional incident. The hysteric was born and not made. The determinant might be really physiological and not psychological; an inherent liability of reaction, a lack of neuronic cohesion, an abnormal facility of dissociation of neural systems. The physiological basis of the will might be inhibition—a "letting go," rather than a "doing"—the essence of the voluntary act. Failure of transcortical control would then explain the phenomena of hysteria. The present trend was to reduce the number of functions once ascribed to volition, and much cortical activity was now regarded as reflex in nature. The cortex could only differ from the other ganglia in its complexity. An approach from below upwards had much to commend it; the gap between physiological and psychological was not likely to be bridged from the psychical side.

AN AMERICAN "PENNY-IN-THE-POUND" SCHEME.—The town of Bedford, Massachusetts, has adopted a contributory scheme on the model of that at Sheffield.

POSITION OF KING'S COLLEGE HOSPITAL.—Dr. Claud P. Serocold, the treasurer, states that "King's College Hospital is in dire straits and can no longer struggle to maintain its precarious foothold against financial difficulties," and that in default of adequate support many wards must be closed. The cost of maintenance exceeds £100,000, and the ordinary income fails to meet it by £18,000. This year securities to the value of £14,500 have been sold, and those that remain are insufficient to meet outstanding accounts amounting to £15,000. An increased income of not less than £20,000 is needed to maintain the work unimpaired. Ten years ago seven wards had to be closed, but "by extraordinary efforts" they were eventually reopened.

JOHANNESBURG HOSPITAL: MAINTENANCE APPEAL.—An appeal is about to be made to South Africans in London on behalf of the Johannesburg Hospital, which claims to be the largest institution for the care of the sick in the British Empire, with 1141 beds distributed among the General Hospital (530 beds), the Non-European Hospital (203), the Transvaal Hospital for Children (133), the City Fever Hospital (90), the Otto Beit Convalescent Home (52), and the Queen Victoria Hospital (43). To the institution is attached the medical school of the Witwatersrand University and a training school for nurses. Last year there were 18,400 in-patients, and 157,000 attendances at the casualty and out-patient departments. The cost of maintenance is £236,500. The Government gives a subsidy of 72 per cent. of expenditure; 24 per cent. comes from patients' fees and other revenue; the public contribute the remaining 4 per cent. Costs have, however, mounted so rapidly that the Government has been compelled to call a halt, and an appeal for more money has therefore become necessary.

THE VISIT OF PROF. CHEVALIER JACKSON.

THE medical profession has had the pleasure of welcoming in London during the past week Prof. Chevalier Jackson, of Philadelphia, whose developments of tracheal and bronchial surgery have for a long time made his name familiar to all our readers.

A Welcome from the Section of Laryngology, R.S.M.

The Section of Laryngology of the Royal Society of Medicine made out an inclusive programme to mark the event.

On Thursday, Nov. 6th, the Section met for a demonstration in colours of plastic operations by Prof. J. Eastman Sheehan, of New York, when Sir Harold Gillies and Mr. Lionel Colledge showed cases illustrating the end-result of such surgical procedures as the excision of costal cartilage for use in facial repairs, the utilisation of skin grafts of full thickness in lupus, and of epidermic grafts in cicatricial contracture of the hand. In the evening an At Home was given by Sir StClair Thomson to meet Prof. Chevalier Jackson and Mr. V. E. Negus, who had delivered the Semon lecture that afternoon (see p. 1086). There was a very large attendance.

On Friday, the 7th, the subject of precancerous conditions in general was reviewed by Prof. Chevalier Jackson in a debate before the Section. He submitted that a knowledge of precancerous conditions would solve many problems of ætiology, and a debate ensued on the general question whether the existence of a precancerous condition had as yet been proved. To that debate Sir StClair Thomson, Mr. Lionel Colledge, Dr. E. D. Davis, Mr. Herbert Tilley, Dr. J. A. Gibb, and Mr. E. Musgrave Woodman contributed, while interesting cases were shown by Mr. W. Stewart, Mr. L. Graham Brown, and others.

A Complimentary Dinner.

A dinner was given on Friday evening, at the Langham Hotel, by the Section of Laryngology in honour of Prof. Chevalier Jackson, when Mr. F. A. Rose, President of the Section, presided over a large company of well-known specialists and representative guests. Mr. Rose proposed the health of Prof. Chevalier Jackson in happy terms. Reminding the audience that Dr. Johnson had said that to praise a man in front of himself was always indelicate and often offensive, he refused to enlarge upon their guest's well-known work, either upon his surgical achievements in carcinoma of the larynx or his famous exploits with the bronchoscope. He aptly compared Prof. Chevalier Jackson with Elias Howe, who invented the sewing-machine—"Howe showed the world that the eye of a needle should be at its point, and Jackson taught the medical world that the light of the bronchoscope should be placed at its tip." It was not for the surgical work and certainly not for the modest manner in which he suppressed his personality, but for his marvellous dexterity with the instrument which he had invented that their guest would be remembered. The toast was supported by Mr. Herbert Tilley, who told Prof. Jackson that, whether the statement was indelicate or offensive, he, as their guest, was surrounded by hero-worshippers.

Prof. Chevalier Jackson, in reply, said that the overwhelming reception which he had received had surprised him. He had been asked what qualities went to the making of a successful bronchoscopist, and he concluded that a man to reach the position must pass endless time in making experiments, many of which led nowhere, and in writing much that no one would read; the successful bronchoscopist was, in fact, a natural born fool. He gave an amusing illustration of his methods, when he described a fishing holiday on which he went, with two doctors who could not fish, to a river where there were no fish. He, for his part, took a small working outfit with him, and spent his time extracting fishhooks embedded in various ways in rubber tubes. He was considered by the mill-keeper, in whose mill the party had lodgings, to be mad, a view which was afterwards reversed, Prof. Jackson being found by the mill-keeper to be, "like myself, a man of high intelligence." The change of opinion was due to the fact that a large foreign body having fallen into the machinery of the mill, the mill-keeper commenced taking down the whole building. Whereupon Prof. Jackson rigged up, on bronchoscopy lines, some appropriate tackle, and extracted the foreign body as though the shaft of the mill were a larynx. Prof. Jackson said that the pleasure of the occasion was for him tinged with sadness for one reason—his father, born in Hull a century ago, could never know the events of the week.

The toast of the guests, other than the guest of the evening, was proposed by Dr. Dan McKenzie, who compared one kind of eloquence to sunshine that illumines the landscape and yet draws no attention to itself, and another kind of eloquence to moonshine that fills us with the sense of its own loveliness, but leaves the landscape hazy. A third kind, he suggested, was represented by the action of Swiss hotel-keepers who insult the majesty of the snowy peaks of the Bernese Oberland by throwing nightly searchlights upon them. As these men are unworthy of the beauty they live in so was he, he feared, unworthy of the task confided to him. He coupled the toast with the names of Sir Humphry Rolleston and Dr. Watts Eden. Mr. Alex. R. Tweedie briefly supported the toast, to which both distinguished guests responded.

Sir StClair Thomson proposed the health of the chairman, with whom he had had the pleasure of travelling on several occasions. He took the opportunity of insisting, for the benefit especially of the younger members of the company, on the enormous value of travel on the Continent and in the great transatlantic countries, while he congratulated Mr. Rose upon the successful commencement of his year of office.

On Monday evening Prof. Chevalier Jackson introduced a discussion on the Diagnosis and Treatment of Malignant Disease of the Chest, at the Medical Society of London; this is reported in another column.

DISTRICT BEDS FOR HOSPITALS.—In the summer of last year Dr. W. Lee suggested that the two Cheshire villages of Bredbury and Romiley should make a concerted effort to endow a bed at Stockport Infirmary and another at St. Mary's Hospital for Women and Children at Manchester, the total sum required being £2000. The population of the two villages is 10,000. The money was raised so easily that it was decided to increase the effort and to add a bed at the Manchester Royal Infirmary, and a cot at the Children's Hospital, Pendlebury, at a cost of £1500 for the two. The "campaign" has just ended with a bazaar which has brought up the total amount raised to £6500. The unexpended balance is to be used for further extensions of the scheme.

REVIEWS AND NOTICES OF BOOKS

Cancer of the Lung
and Other Intrathoracic Tumours.

By MAURICE DAVIDSON, M.A., M.D., Physician to the Brompton Hospital for Consumption and Diseases of the Chest, and Dean of the Brompton Hospital Medical School. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Ltd. 1930. Pp. 173. 17*s.* 6*d.*

THE literature of intrathoracic tumours has increased rapidly during the last decade. Dr. Davidson's book is based on the findings in a number of cases which have been treated in the Brompton Hospital. Short clinical notes and histories of 22 cases of intrathoracic tumour are given. Unfortunately, in three of the cases recorded, no post-mortem examination was made, and in about half of them no histological data are furnished, so that the exact nature of the tumours in these cases is uncertain. The clinical part of the work should be of much value. It is brief, concise, and very readable. Apart from the implication made that intrathoracic tumours are not especially characterised by pain, the author's findings are generally in accordance with those of other writers. Valuable information is given on diagnostic methods, such as lipiodol injections and bronchoscopy, and a helpful note on radiological technique is supplied by Dr. Stanley Melville. The section on pathology is somewhat sketchy. The discussion is confined practically entirely to problems of bronchial carcinoma; lymphosarcoma of the mediastinal glands is mentioned only to be dismissed as a condition for which bronchial carcinoma used, in the past, to be mistaken. The cases described, however, have not been limited to those of carcinoma of the bronchus; in Case 4 and Case 22 there appears to have been no bronchial or lung involvement; one of these was cited as a thymoma. In a separate section of the book certain non-malignant tumours, including dermoids and hydatid cysts of the mediastinum, are considered.

The Child's Conception of Causality.

By J. PIAGET, Professor at the University of Geneva. Pp. 309. 12*s.* 6*d.*

The Laws of Feeling.

By F. PAULHAN, Academie des Sciences Morales. Translated by C. K. OGDEN, M.A. Pp. 208. 10*s.* 6*d.* Both volumes published by Kegan Paul, Trench, Trübner and Co., Ltd., London. International Library of Psychology and Scientific Method. 1930.

THE first of these two books takes a stage further Prof. Jean Piaget's investigation of the child's world. The research is conducted in the familiar questionaire form made known to all readers of the author's early volume. The child, according to the author, starts with a view of the world which is essentially animistic. At first the lack of distinction between an inner and outer makes the world participate in the child's mental activities, and for some time the world interlocks organically with the processes of mind. During the period of severance, however, the mind still clings to this outer order, giving it consciousness, and causing it to retain some of the human attributes. According to the author's researches, this animism is reluctantly given up, and gives to subsequent ideas of causal relationship an "agency" which, even in philosophic thought, is not entirely relinquished. Five varieties of such "adherences" of subjective factors to the view of the external world have been described by Prof. Piaget—ranging from the early magical belief, through artificialism and thence to the idea of force—i.e., that things make efforts—analogous to muscular force. The transition to simple realism is achieved when the child appreciates its own subjectivity. But even then there is an absoluteness in its idea of substance in the passage to relativity and reciprocity. The development of causality in the child takes place along the same lines as does the construction of an external world of related parts, each and all related to the observant mind.

Prof. Piaget's conclusions from his interrogatories may not satisfy certain critics as to the animism of the child. It savours of the French anthropologists who separate categorically a primitive prelogical from a developed logical form of thought. However this may be, his studies are stimulating to thought, and, above all, to further researches in the same field.

Students of instinct and emotion, particularly in England, have been captivated by the exposition of Prof. McDougall in his Social Psychology. Some have eventually grown restless over his catalogue of instincts and their accompanying emotions, yet have felt unable to formulate trenchantly a counter theory which would be as comprehensive, as easy to handle, and yet conform as well and even better with the facts of psychology. Paulhan's essay on the Laws of Feeling, now accessible in English, brings forward a powerful thesis which not only allays much of the dissatisfaction felt over McDougall's standpoint but compensates for many of the shortcomings in psychology that created a hiatus between it and neurobiology. His thesis—that feeling and emotion are the result of arrested tendencies—will find many adherents in the apparently separated realms of biology and psychopathology. Such a theory is much more dynamic than any theories that have gone before, and fits the moving facts of life better than does an academically static catalogue. The author argues his thesis with abundant examples, acute insight, and the usual Gallic clarity and devotion to logic. The addition of a later essay on Feeling, Will and Intelligence concludes an important volume which should not be missed by students of psychopathology.

Röntgenuntersuchungen am Innenrelief des Verdauungskanals.

By Dr. HANS HEINRICH BERG, Professor at the University of Berlin; Senior Physician at the Charité University Clinic. Leipzig: Georg Thieme. 1930. Pp. 198. M.29.

THE X ray study of mucous membranes originated with Forssell of Stockholm, who, in a number of papers, drew attention to the fact that the radiologist may obtain much information about the lining membranes of the alimentary tract if suitable methods are employed. Prof. Berg has already made several important contributions to the subject, and this book is an expansion of his previous work. A few minor modifications of the ordinary opaque meal technique bring to the service of the radiologist the means of studying the living mucous membrane. Many of the

workers who employ the combined screening and palpation method for opaque meal investigations have for years past used the manipulation of the first mouthful as it reached the stomach for the demonstration of the folds of the mucous membrane. Berg has elaborated this technique in various ways, and extended it to the intestinal mucosa with most telling results, and it is not easy to over-estimate the diagnostic possibilities that are thus foreshadowed.

An extraordinary wealth of detail is revealed by the arduous technique. So trying is it, that seemingly no observer can undertake more than six cases in a day, the intensive palpation and manipulation being so exhausting. In the present state of our knowledge, detail obtained by these advanced methods is perhaps an embarrassment, for it complicates the problems of the diagnostician. The nearer we approach to the borderland where pathology and normality meet, the larger the number of borderland cases and the more difficult it is to differentiate. A thorough understanding of the possible variations of the normal becomes more and more essential for accurate diagnosis. These painstaking studies will be the basis on which Dr. Berg and other investigators will assuredly build up an entirely new conception of the normal and abnormal mucous membrane.

The book is illustrated by numerous radiograms and photographs of pathological specimens. All the illustrations are of a very high order of technical excellence.

An Hour on Health.

By MORRIS FISHBEIN, M.D., Editor of the *Journal of the American Medical Association*. London: J. B. Lippincott Company. Pp. 158. 4*s*. 6*d*.

THIS is a very readable little manual on healthy living, written obviously for the American business man, and the advice which is given him about his diet, rest, golf, and other recreations is both sound common sense and good physiology. The style is crisply American, and there are some amusing passages, more especially in the chapter on food fads and fallacies. The author has little patience with vegetarians, white bread fanatics, and cold bath enthusiasts. The Americans, he tells us, are a constipated people, but because of, or in spite of, this, "five generations of them, fed on meat and potatoes, develop sufficient stamina to contribute largely towards winning the World War." The prevention of heart disease is dealt with vaguely, and contains no reference to the method of direct attack on the incipient disease which has given such encouraging results in this country where, incidentally, the view accepted by the author that chronic tonsillar sepsis is a prime factor in the ætiology of juvenile rheumatism has not been substantiated. The last chapter, entitled Medicine in our Changing World, sets out the author's own views on various medico-political questions of the day. From many of these the English reader will dissent. With the truism that "the sick human being demands individualisation" the counter-advantages of team-work in the alleviation of human ills are rather lightly dismissed. In this chapter Dr. Fishbein lets his fancy have free play, and if his approach is not strictly scientific it is always interesting.

Journal of Pathology and Bacteriology.[1]

THE importance of venous invasion in the development of metastatic tumours in the liver, by R. A. Willis (Melbourne). The primary metastases invade the portal veins and so produce secondary crops.—*Spirillum minus* derived from a spontaneous infection in the mouse, by J. A. W. McCluskie (Glasgow). The strain was not pathogenic for guinea-pigs or man and may not be identical with the similar organism in rats which causes rat-bite fever.—Bacteriæmia following operations on the urethra, by F. J. F. Barrington and H. D. Wright (London). After the passage of bougies in an infected urinary tract, bacteria often invade the blood stream at once and soon disappear; malaise and rigors appear when the blood is sterile (see p. 1087).—The pharmacological action of the exotoxin of *Staphylococcus aureus*, by C. H. Kellaway, F. M. Burnet, and F. E. Williams (Melbourne). The main effect is a large fall of blood pressure, due partly to obstruction of the circulation through the lungs, and partly to a direct action on the myocardium.—The reactions of the cells in pleural effusions to supravital neutral red, by R. A. Hickling (London). Endothelial cells are by this method clearly distinguished from monocytes.—Reactions of the human skin to horse serum, by C. E. Kellett and H. D. Wright (London). The intracutaneous injection of horse serum in normal persons may be followed a few days later by a series of urticarial whealings which are presumably analogous to serum sickness.—The effect of immunisation upon temperature response in rabbits, by H. D. Wright (London). Vaccination reduces but does not abolish the fever which follows the inoculation of the dead homologous organism.—The staining of calcium, by G. R. Cameron (London). Neither hæmatoxylin nor silver nitrate is a reliable reagent for the microscopic detection of calcium salts; alizarin is nearly specific but not altogether easy to apply in practice. It stains recent deposits much better than old ones.—The pathological changes found in a fatal case of psittacosis, by G. H. Wilson (Birmingham). The consolidation of the lung is lobar with abundant fibrin formation, but there is no reaction by the polynuclear leucocytes and the bronchioles are not specially involved.—Isohæmagglutinins: the influence of the fœtus upon the titre of the mother's blood during pregnancy, by Kathleen Edgecombe (Liverpool). If the fœtus is of a different blood group from the mother, there is a considerable rise in the effective agglutinins in the mother's blood during pregnancy which disappears after childbirth. With a fœtus of the same or no group, little or no change occurs.—Anaphylactic responses of the guinea-pig's skin, by C. E. Kellett (London). Contrary to the usual experience, it is possible to produce serum sickness in a guinea-pig.—Schilder's encephalitis periaxialis diffusa in a rhesus monkey, by J. R. Perdrau (London).—Persistent eosinophilia, by A. M. Drennan and J. H. Biggart (Belfast). A case of leukæmia with considerable nodular deposits in which the neoplastic cells were sufficiently differentiated to appear as normal eosinophil leucocytes.—The pathological action of light: the repair of necrosed tissue, by A. G. Levy (London). A smaller dose of destructive stimuli causes considerable epithelial proliferation.—A case of tuberculosis of the stomach, by E. R. Cullinan (London). A boggy lesion at the cardiac end full of acid-fast bacilli; the lungs showed general miliary tuberculosis.—The influence of liver extract effective in pernicious anæmia upon the diameter of erythrocytes in experimental anæmias, by G. P. Wright and B. Arthur (Boston). Liver extract has no effect on the blood of normal rabbits, nor does it assist the cure of experimental anæmias caused by bleeding or phenylhydrazine. It, however, reduces the severity of phenylhydrazine anæmia. It is suggested that liver extract cures pernicious anæmia by promoting the orderly degeneration of the megaloblastic phase of the erythropoietic cycle.—Sacral chordoma with widespread metastases, by R. A. Willis (Melbourne). Secondary growths were found in lungs, heart, liver, spleen, kidneys, thyroid, and skin, and a number of bony exostoses were also present.—The influence

[1] Vol. xxxiii., No. 4, pp. 849–1174, October, 1930.

of testicular extract on dermal permeability and virus response, by D. McClean (London). Testicular extract improves the taking capacity of some strains of vaccine virus; it enables the inoculum to spread out among the cells more quickly after insertion.—Necrotic sequestration of the kidneys in pregnancy (symmetrical cortical necrosis), by W. de M. Scriver and H. Oertel (Montreal). Two cases confirmed post mortem and one which recovered.—Coal-miners' lung, by S. L. Cummins and A. F. Sladden (Cardiff and Swansea). A full account with many chemical analyses of lungs. Coal dust becomes important if it has been preceded or is accompanied by silica dust, which blocks the lymphatics and allows the coal dust to accumulate. Serious anthracosis always shows an abnormal amount of silica in the lung.—A further contribution to the pathogenesis is experimental poliomyelitis: inoculation into the sciatic nerve, by E. W. Hurst (London). The virus spreads along the axons; the cerebro-spinal fluid is relatively unimportant. After sciatic inoculation the virus can be found in the corresponding motor cortex before it can be detected in the cervical cord.—The types of tubercle bacilli occurring in the sputum of phthisical persons, by A. S. Griffith (Cambridge). Fully tested and verified bovine bacilli have been found in the sputum of cases of phthisis in England in 3 cases out of 327 examined, in Scotland in 18 out of 468. In two bovine bacilli were also obtained from the lungs at autopsy.—Direct platelet counting, by H. K. Goadby (London). He uses paraffin-lined pipettes.—Individuality in the size of red cells, by C. Price-Jones (London). Each person has a characteristic mean diameter of red cell which is maintained over long periods.

PANEL AND CONTRACT PRACTICE

London Public Medical Service.

The Public Medical Service for London came into being in the spring of 1926, when rules were framed by the members of the London Panel Committee, the British Medical Association, and the Medical Practitioners' Union, who were instrumental in its inception. Its main ideal was to provide medical attendance and medicine by a contributory scheme for persons unable to pay the usual medical charges in the ordinary way, the income limit being fixed at the same figure as that under the National Health Insurance Acts—namely, £250 per annum. At the same time it was agreed that the practitioners who implemented the service should receive adequate remuneration. With these points in mind the weekly payment of a subscriber was fixed at 3*d.*, an entrance fee of 1*s.* and a quarterly levy of 9*d.* being charged to cover the cost of administration. In this way a practitioner was to receive 13*s.* per annum for each subscriber, out of which medicine had to be provided. The average cost of medicine per subscriber per annum is computed at 2*s.* Recently a flat rate of payment has been introduced in the Kensington and Paddington areas, where the local committees found that the separate payment of a quarterly levy was irksome. In these areas the rate for a single subscriber is 4*d.* (the doctor reserving the right to charge 6*d.* a week if the risk of sickness seems likely to be above the average), for two in family 8*d.*, for three 11*d.*, for four or more 1*s.* 1*d.*, the entrance fee being 1*s.* for one subscriber and 2*s.* for two or more. A percentage deduction is made for administration in the areas where the flat rate operates.

The service was inaugurated at a series of local meetings in the various London boroughs, and by the end of 1926 the subscribers numbered a little over 5000. Since then progress, though not realising the expectations of the management committee, has been steady. The latest figures are as follows:—

Number of practitioners working the Service	402
Number of honorary members (i.e., practitioners not working the Service but who are in agreement with its principles and wish to be associated with it) ..	110
Number of subscribers	11,461

Although 11,461 subscribers may not seem a large number for an area like London, it should be remembered that the service was inaugurated just when the disastrous strike of 1926 occurred. Another source of loss has been the removal of working-class population from the Metropolis to London County Council estates which are outside the area of the service. Deaths, removals, discontinuance of subscriptions owing to unemployment, subscribers becoming eligible for treatment under the National Health Insurance Acts, all contribute to limit the total number of subscribers. The main difficulty has been in making the public aware of the existence of the service. The restriction on public announcement is felt to be somewhat hard on a movement which is endeavouring to do its share in assisting the community towards the goal of better health. Signs are not lacking, however, that the public is beginning to realise the existence of the service; subscribers are now coming in at the rate of 100 a month, and an increasing number of inquiries are being received at the head office, 17, Russell-square, W.C. 1.

The Patient who goes to a Bonesetter.

"If an insured person," we have been asked, "with an injury to the shoulder, fails to keep an appointment made by her panel doctor to see a surgeon in a neighbouring town, but goes instead to an unqualified bonesetter and continues to go to him for treatment is the panel doctor justified (1) ethically, (2) under his terms of service, in refusing (*a*) to treat her, should she subsequently apply to him for treatment, (*b*) to give weekly certificates of incapacity for work, should she apply for them?"

Answer.—1. Ethically the panel doctor is quite justified in refusing both treatment and service.

2. (*a*) Under his terms of service it is open to argument that the refusal might constitute a breach of contract with the insurance committee. The insured person has been guaranteed medical benefit and if she applies for treatment it is difficult for the practitioner to refuse. She has, however, made it difficult, if not impossible, for him to render the proper treatment if she puts herself into the hands of an unqualified person. The proper course would be to report the facts to the insurance committee, in order to protect himself from their criticism and subsequent action.

2. (*b*) With regard to sickness benefit the panel doctor has to deal with the approved society of which his patient is a member. Supposing that the action of the insured person is not conducive to speedy recovery, he should withhold certificates and report the matter to the society, which may refuse benefit to a member found guilty of infringing the benefit rules. Moreover, as a general rule, the practitioner should not give certificates where he is not rendering the treatment himself. Before being in a position to certify, he has to make a complete examination, and difficulties will arise unless he is making this examination as a preliminary to advice and treatment.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 15, 1930.

INTERNATIONAL MEDICINE.

THE League of Nations has now reported upon its work during the first ten years of its existence,[1] and the record sets forth briefly and impartially both the progress which has been accomplished and the methods which have been devised for dealing with international problems as they arose. The League represents aspirations that have been set before the world for some 200 years, but in its practical form it was born of the Great War with the purpose to abolish war. It came into being in 1919, when the political, financial, and economic crises, whose settlement was urgent, while they may have revealed to the observant the gigantic tasks that would lie before the new institution, deflected from it public attention. The statesmen of the world were absorbed in dealing with these crises, whose effects fastened the thoughts of each nation on its own affairs. Thus the early proceedings of the League were little noticed and the excellent account, now given, of what has been done and why certain activities were undertaken, and how, in consequence, other activities followed, will have for many the force of novelty. Further, the tale of performance must convince all who read it carefully that the League is a necessity—that it is an organisation which has already achieved great things, and one which must be in the future of incalculable benefit to the world.

It is a commonplace that in medicine we have a department of knowledge which is truly international; the practice of medicine itself forms an international league as different nations enter into scientific relations with each other. In the efforts made to settle frontiers, to codify international law, to bring about coöperation along financial and economic lines, to organise disarmament, and to settle disputes by arbitration, there must always be room for qualifying discussions; but there can be no two opinions as to the benefit to the world of international schemes for the promotion of health. A nation must consider itself outraged if an historic province be taken from it to be added to the possessions of a neighbour, but no nation will have any objection to being robbed of its burden of sickness; and while commercial tariffs cannot be altered for the benefit of one people or industry without the risk of inflicting corresponding damage elsewhere, the improvement of health in any place on the globe tends to improve the health of the world at large. This was recognised by the delegates composing the earliest assembly of the League, and in the second meeting of the Council, held in February, 1920, only a few weeks after the settlement of the constitution, it was decided to summon an international meeting of health experts to draw up a scheme of organisation. And none too soon. For in April of that year epidemics of typhus, relapsing fever, and cholera, spreading from Russia towards the west, called for urgent measures, and the first duty of the international conference was the erection of a temporary Epidemics Commission. The strenuous work of this Commission was chronicled from time to time in our columns, and there is no doubt that, by the strength and authority which it gave to Poland and other countries in the institution of a sanitary cordon on the frontiers of Russia, it saved mid-Europe from devastating disease. While the Epidemics Commission was thus employed, a provisional health committee, which had been set up at Geneva, worked out the scheme for the Health Organisation of the League, which was adopted in September, 1923, when the relations of the League with the previously existing international official health authority, the Office International d'Hygiène Publique, were settled. The settlement was effected partly on the basis of official liaison, partly by the delimitation of function under which the older body has since continued and developed as its own the task of preparing and supervising formal agreements between Governments, on quarantine, and other medical administrative subjects. The proceedings at this Assembly of the League, as far as they related to medicine, were of extreme interest, and indeed made it quite evident that the League did not require to establish any monopoly in order to break the new and fruitful ground which was ready. The basis of permanent organisation, the international differences in mortality from diseases like cancer and the comparative figures in other diseases, the incidence of malaria and sleeping sickness, and the international standardisation of serums were among the subjects discussed, and the verbal views were immediately reflected in practical work which is now proceeding; this those specially interested have been able to appreciate in official publications, many of which have been noticed in THE LANCET.

Among the earliest activities of the Health Organisation was the collection and distribution of medical news. An epidemiological intelligence service was set up at Geneva and a bureau of information upon tropical maladies was instituted at Singapore. A dissemination of morbidity and mortality statistics followed, utilising and popularising that provided by the international agreements. This has been especially valuable in epidemiology, since here, before useful work can be done, the relative importance of the diseases must be ascertained. The first practical workers for the League knew this from experience, for the efficacy of the prophylactic measures taken along the Russo-Polish borders depended upon the interchange of

[1] League of Nations: Ten Years of World Coöperation. Foreword by Sir Eric Drummond, Secretary-General of the League. London: George Allen and Unwin, Ltd. 1930. Pp. 467. 10*s*.

prompt and full information across the frontier. All these matters are clearly set out in the new publication of the League Secretariat, which gives a clear story of the development of the League, and of international medicine under its auspices. It is a comprehensive and authoritative statement of the facts, and there is a happy omen in testifying to the value of the League of Nations within a few hours of Armistice Day.

CARBUNCLES AND X RAYS.

THE indications for radiotherapy in the treatment of skin diseases are in many ways indefinite, but increasing experience shows that in this branch of treatment X rays are the most useful single remedy we possess. From this point of view the various dermatoses fall into three groups. The first comprises those in which radiotherapy is the only means of affording cure or relief, and includes mycosis fungoides, inoperable tumours, regional hyperidrosis, and certain types of localised pruritus. The second group, by far the largest, is made up of conditions which respond best and most conveniently to the action of the rays, and includes acne, certain types of eczema, keloids, trichophytosis, and ringworm of the scalp. In the third group we may put lesions which respond only in selected cases and in which the remedy should be applied only after the failure of the other methods; examples of these being rosacea, lichen planus, leucoplakia, warts and condylomata, chilblains, and certain stages of lupus. Possibly a fourth group might be added in which, although results may be expected, the required dosage is too high for safety. A notorious example of this is hypertrichosis.

On theoretical grounds the treatment of septic conditions by X rays has always been regarded as hazardous, and yet if we consider the case of acne, which can hardly be described as amicrobic, we are faced with an exception which furnishes the X ray clinic with a notable percentage of its skin patients. This disease, which in its pustular stage is the result of staphylococcal invasion, is always benefited by a few carefully chosen and spaced doses of X rays, which suggests that other staphylococcal infections may be equally amenable, and such considerations may have led to a trial of radiotherapy in carbuncle lately described by LIGHT and SOSMAN.[1] In their report these workers analyse the results in 50 cases, and frankly confess that "radiation is not consistently followed by improvement"—an admission which argues unusual scientific detachment. LIGHT and SOSMAN believe that any benefit observed was due to acceleration of the necrotic process in the carbuncle, "a softening in the indurated stage," with consequent prevention of extension, "in a few instances." The treatment was occasionally given with success after surgical measures had failed to check the infective process; on the other hand, there was one case in which both methods failed and the patient died. Pain was relieved in a few cases, especially those in which the carbuncle appeared on the lip or cheek. Of the 50 cases cited, 34 appeared to benefit, and 16 did not appear to respond at all. Eight out of the nine carbuncles on the face "responded excellently," and (which may be significant) the larger the lesion the less was it influenced favourably. On the information given, and with no simultaneous controls treated by other methods, it is obviously difficult from this paper to assess the value of X rays in the treatment of carbuncle. It would be interesting to observe the effect in a case with two carbuncles, or, since these are very rare, in multiple furuncular lesions, one or more of which might be treated by X rays for comparative purposes.

The dermatological attitude to X rays is nowadays undoubtedly less stringent than it used to be. It is well known that furunculosis of the neck in its most chronic and obstinate form (dermatitis papillaris capillitii of Hebra) is amenable to X rays, and that if boils continue to appear in one area only, the use of X rays is justifiable. In two conditions, however, the application of this remedy is by general agreement disallowed—namely, psoriasis, because the disease tends to recur whatever treatment is given and the repetition of X rays indefinitely is highly dangerous, and hypertrichosis, because it is technically impossible to destroy the hair follicle without damaging the blood-vessels and elastic tissue in the area irradiated. The doses advised by LIGHT and SOSMAN for the treatment of carbuncle are well outside the zone of danger, being only 30 to 50 per cent. of the erythema dose, both with and without filtration; and in the latest American text-book[2] it is asserted that for the deep type of carbuncle "radiation therapy is invariably of some benefit, preference being given to filtered X rays." We have as yet no truly specific treatment for this condition, and until one is provided there seems to be a relatively good case for trying X rays before resorting either to surgery or the diathermy current.

THE TREATMENT OF FRACTURES.

THE main principles guiding the treatment of fractures are now well established. For closed fractures the requirements may briefly be stated as immediate restoration of the alignment of the fragments, their maintenance in position until firm union has taken place, and early attention to the circulation and general function of the limb. For open fractures we must add thorough cleansing of the wound by excision in the first instance, and a minimum of interference afterwards. These requirements, which are interdependent, must be the basis of any treatment of injuries to bone. ARBUTHNOT LANE, with a clear conception of the essentials, introduced open reduction of fractures and fixation of the fragments by metal plates. His teaching focused attention on the then inadequate methods of treatment and brought about a demand for its improvement, coinciding with a

[1] Light, R. U., and Sosman, M. C.: New Eng. Jour. Med., Sept. 18th, 1930, p. 549.

[2] Andrews, G. C.: Diseases of the Skin, Philadelphia, 1930, p. 522.

more general use of X rays for diagnosis. But progress was somewhat prejudiced by a sharp division of opinion into two schools, the non-operative and the operative, since it was not realised then—and perhaps is not fully now—that the two apparently opposite methods are really part of the same treatment, inasmuch as failure of non-operative measures in any particular case leads to a demand for open reduction. Nevertheless, surgeons were stimulated to aim at perfection of alignment even when they preferred not to undertake an open operation which, except in the hands of the few, had its obvious dangers; the vast amount of material available during and since the late war has made it possible to do much work on the subject. Hence, many methods have been advocated, with a widely varying technique, and by their very number these have led to a certain amount of confusion, so that a feeling of uncertainty has been created among practitioners, away from the large centres, who are called on to deal with severe injuries in increasing numbers. An urgent demand has, therefore, arisen for means of treatment which are not too complicated and ensure a good prospect of success, and for this reason the procedure employed by LORENZ BÖHLER, of Vienna, will probably find an increasing number of followers. BÖHLER has demonstrated a technique by which the essentials of treatment can be carried out without undue difficulty, mainly by an extensive use of transfixion pins through which traction is exerted and maintained by embedding the pins in plaster-of-Paris casts.

Whatever may be said about methods of treatment, the desire to treat fractures is probably individual. Those interested in the subject usually evolve a technique of their own and get good results with it, but to impart their knowledge to others working under different and less favourable conditions is peculiarly difficult. Moreover, many practitioners suffer a considerable handicap through feeling that they have neither the equipment nor the time for the close personal attention necessary to success, and accordingly look on severe fractures with a feeling of apprehension. These various factors account for the frequent statement that fracture treatment has lagged behind the other achievements of surgery during the past 25 years. This statement is not wholly true; the advance has been real, and there are few fractures which still defy reduction by one means or another, while the period of incapacity has been definitely reduced by early physiotherapy. Nor does it seem likely, for the time being, that there will be any radical alteration in the accepted methods of treatment—though details of technique may improve—and further advance must therefore be looked for in the better organisation of cases in general, and easier access to the best treatment available, which does not necessarily depend on outstanding individual skill so much as on sufficient equipment and general capacity. In Vienna, mainly at the instigation of Prof. BÖHLER, the insurance companies have become interested in the organisation of fracture work; in the United States the whole problem is under consideration by a committee of the American College of Surgeons; and we hope that before long it may receive attention from the proper authority in this country too. The solution is probably not easy but it seems that there should be a fracture clinic in every large centre, which should be able to exert a measure of control over its district. Such centres should be in close association with the smaller and cottage hospitals, and it ought not to be impossible to organise a service which could send a trained team with full equipment to any point in its area. Some such scheme would not only lighten individual responsibility but would give a greater sense of security to all concerned, while incidentally it would afford a means of spreading instruction in treatment.

Finally, education of the public is called for. It is natural to feel irritation at any accident, especially if it may mean loss of work or prolonged incapacity without compensation, but too often this irritation leads to resentment at any loss of function and perhaps a claim for damages against those who happen to have been called in professionally. The fracture has been too long regarded as a "simple" affair in which perfect "setting" can be performed without difficulty under any circumstances. A better knowledge of the facts might finally induce greater coöperation in any scheme for improvement.

PUBLIC HEALTH CONGRESS AND EXHIBITION.

AN official programme has been issued of the congress to be held at the Royal Agricultural Hall, London, from Nov. 17th–22nd, under the auspices of the various municipal associations interested in public health administration. On Monday the congress will be opened by Mr. Arthur Greenwood, Minister of Health, and in the afternoon will be addressed by Sir Arthur Newsholme on Medicine and the State. On Tuesday morning Dr. W. M. Ash will introduce the School Medical Service, Dr. J. R. Kaye presiding; the subject on that afternoon is Physical Education in the new Senior Schools. On Wednesday morning Mr. I. G. Gibbon, of the Ministry of Health, will speak on the Place of the Open Space in Modern Social Economy; in the afternoon Prof. E. Mellanby will consider Maternal Mortality. Thursday will be given up to problems of mental health; Dr. T. Beaton will deal with Some Practical Aspects of the Problem and Dr. E. S. Litteljohn with the Social Problem of Mental Deficiency. On Friday morning the Sterilisation of the Unfit will be discussed from various sides by Dr. C. P. Blacker, Dr. W. F. Menzies, Dr. A. F. Tredgold, and others; in the afternoon Prof. C. S. Myers will give an address on Industrial Psychology in relation to Public Health. The various associations will hold their own meetings during the week. We call special attention to a discussion on Hospital Libraries initiated by the Joint Red Cross, on Nov. 21st, at 3 P.M., when Sir Arthur Stanley will preside, and among others Mr. L. G. Brock, Sir Alfred Davies, Dr. H. L. Eason, Dr. Doris Odlum, and Miss M. E. Sparshott will speak. An exhibition of machinery and materials used in the various public health services will be open every day from 10.30 A.M. to 9 P.M. Sir Frederick Willis is chairman of the organising council, the hon. secretary of which may be addressed at 13, Victoria-street, London, S.W. 1.

ANNOTATIONS

VIEWS ON FIRST CAUSES.

A LITTLE obscured by the title of A Medical Service for the Nation, a discussion has been going on in our correspondence columns as to the proportion of the nation which is economically worthy of individual medical attention. On one side Dr. Bodman has contended that the factors of heredity must influence very largely the potentialities for disease, irrespective of environment, and he has no doubt that a relative increase of ethically and men tally inferior people is taking place. On the other hand, Mr. Layton does not believe in this increase, and challenges the data from which it has been deduced. He can see no sign of deterioration, and maintains that every Englishman comes from equally good stock and stands the same chance of having had a good ancestry whatever the financial position or social status of his immediate forebears may have been. In his Lloyd Roberts lecture, delivered in the medical school of Manchester University on Friday, Nov. 7th, the Bishop of Birmingham (Rt. Rev. W. Barnes) closely examined these rival views. He dealt specially with the inheritance of feeble-mindedness, which he described as the most socially dangerous type of mutation which has arisen in humanity. Why, he asked, is the gene, or group of genes, producing feeble-mindedness now so widespread in the population? And his confident answer was that our human instincts have caused us to modify the harsh social conditions under which many of the mentally defective would have been eliminated as soon as a new mental-defect mutation appeared. In nature deleterious mutations are constantly arising, and as constantly being suppressed by a hostile environment. Dr. Barnes has been able to discover no evidence that mutations dominate the trend of evolution. They merely appear; the power of the environment does the rest. As he sees the matter, good and evil arise with equal frequency in the variations associated with heredity, but the creative process of which we are products is active through the environment. He felt surprise at his inability to discover in the genetic mutations which are the raw material of evolution any moral quality; but perhaps, he added, the conclusion ought not to surprise us, for whenever we think to discover God at work further knowledge reveals a mechanism behind which He remains hidden. He concluded his lecture, however, by ranging himself with the thinkers who cannot fit righteousness and truth into a mechanical universe. It is significant that almost at the same time as Dr. Barnes was surrendering evidence of design in the gene's mechanism, the Rede lecturer was finding it in the universe outside. In his lecture delivered at Cambridge on Nov. 4th, Sir James Jeans pictured the birth of the solar system and found it incredible that the universe can have been designed primarily to produce life like our own. Had it been so, he said, surely we might have expected to find a better proportion between the magnitude of the mechanism and the amount of the product. He went on to describe the outstanding achievement of twentieth-century physics as a recognition that we are not yet in contact with ultimate reality. In terms of Plato's simile, imprisoned in our cave we can only watch the shadows on the wall. We have no extraneous standards against which to compare them. The real essence of substance, in Locke's phrase, is for ever unknowable, but yet by a very different route modern science has been leading the Rede lecturer to a philosophy summed up by an earlier bishop in the words, "All the choir of heaven and furniture of earth . . . have not any substance without the mind." The river of knowledge, said Sir James, has made a sharp bend in the last few years. Mind no longer appears as an accidental intruder into the realm of matter. We are beginning to hail it as the creator and governor of the realm of matter. Not, he added, our individual minds, but the mind in which the atoms, out of which our individual minds have grown, exist as thoughts; the universe shows evidence of a designing or controlling power that has something in common with our own individual minds.

SECRETION OF MUCUS BY THE COLON.

THE lining membrane of the colon is particularly rich in mucin-secreting or "goblet" cells, which are placed thickly on the inner layers close to the lumen of the bowel. While mucus is not obviously present in normal stools, small amounts are usually found coating scybala and inspissated masses of fæces in constipation. Large quantities of mucus may be passed in the condition known as mucous or mucomembranous colitis, and at times strings or casts are expelled with or independently of a motion. Following Nothnagel, this syndrome is generally attributed to hypersecretion on a nervous basis—a secretion neurosis. The casts consist of pure mucus with little cellular content; if leucocytes or many epithelial cells are present the condition is regarded as inflammatory or true colitis.

Certain of the glands in the upper alimentary tract, the salivary glands, for instance, and the glands of the bronchial mucous membrane, are known to be under the influence of the nervous system; secretion of mucus can be obtained by stimulation of the appropriate nerves or by administration of pilocarpine, while drying up of secretion is brought about by atropine—these drugs acting through the nervous system. H. Florey[1] now brings forward evidence that the secretion of mucus in the colon is a result of direct mechanical or thermal stimulation of the goblet cells, obtained without the intervention of the nervous system. It has been impossible by histological methods, he points out, to demonstrate nerves running to the epithelial cells of the colon. Portions of the colon, isolated by surgical means, and observed through fistulæ, secrete mucus in small amounts only, but much secretion of mucus is obtained when the mucosa is stimulated mechanically by rubbing or even by exposure to air, and chemically by such substances as mustard oil. This secretion is limited to the area which has been stimulated, and other parts of the colon are not affected, as they would be if nervous reflexes were involved. Indeed, a profuse secretion of mucus is seen in response to rubbing or mustard oil in a portion of colon grafted into the abdominal wall and isolated from its intrinsic blood-vessels and nerves by section of these. Florey obtained no evidence that stimulation of either the nervi erigentes or the sympathetic nerves to the colon is capable of stimulating the goblet cells to produce mucus. Large doses of pilocarpine injected intravenously and acting over prolonged periods are

[1] Brit. Jour. Exper. Path., 1930, xi., 348.

required to evoke secretion of mucus in the colon; and in such cases the goblet cells may be stimulated mechanically as a result of the violent bowel movements produced. On the other hand, secretion of mucus is readily obtained by mechanical or chemical stimuli applied locally to the colonic mucosa. Accompanying this secretion there is a local vascular dilatation, and it is of interest to study these phenomena in a little more detail in order to see if they may be brought into line with the results obtained by Sir Thos. Lewis in local reactions of the skin in the early stages of inflammation. Lewis has shown that in the skin the vascular and other phenomena of inflammation are brought about through the medium of a histamine body produced as a result of protein breakdown by the noxious stimulus. Florey's observations have led him to conclude that the secretion of mucus and the vascular dilatation are independent phenomena. He found that the injection or local application of histamine acetylcholine, adenosine, and peptone solutions failed to stimulate mucus-production from goblet cells. It appears, then, that the goblet cells directly react to the insult of the noxious agent, in contradistinction to the accompanying vascular reaction which, judging from the results on skin, is due to the liberation of some histamine-like body.

Florey's paper is full of interest and his thesis is well argued. But clinicians, while agreeing that the goblet cells of the colon pour out their secretion in response to local stimulation, will perhaps hesitate to subscribe to his contention that the secretion of mucus in mucous colitis is independent of the nervous system. The ætiological factors in mucous colitis are obscure enough, no doubt. It is hardly a clinical entity, but rather a collection of symptoms in which the underlying factor is an instability of the reactions of vasomotor, cutaneous, and sexual systems as well as the alimentary. That the nervous system takes no part in this symptom-complex is a view that cannot lightly be accepted on the results of some negative laboratory experiments.

VICARY'S PREDECESSORS.

Thomas Vicary was Serjeant Surgeon to King Henry VIII. and Master of the Barber-Surgeons Company, whose modern counterpart endows a lectureship in anatomy or surgery to commemorate his name. The lecture this year was delivered on Nov. 6th, in the theatre of the Royal College of Surgeons of England, by Prof. G. E. Gask, who took as the title of his lecture "Vicary's Predecessors," his object being to rescue from oblivion the names of those men, famous in their day, who had served the sovereigns of this country before Thomas Vicary. The earliest appointment given was that of Baldwin, Abbot of Bury St. Edmunds, who was the medical attendant of Edward the Confessor and described as a man "gretly expert in the craft of medycyn." At first the royal attendants were described as *medici regis*, surgery not having then been divorced from medicine, but in the reign of Henry III. the appointment bore the title *chirurgicus regis*. "Master William the King's Surgeon," was then presented to "the Church of Houkerinton, in the same diocese (Lincoln) in the King's gift by reason of the land of Thomas, son of Walter being in his hands." This Master William may be regarded as the first of Vicary's predecessors, and from this time on there is a continuous record of regal surgeons. Of some little is known but the name and the salary, ranging from £10 to £40 a year, to which were often added gifts of livings and lands as a reward of faithful service. Thomas de Weseham, surgeon to Henry III., was remarkable among other things for being granted a die for minting silver pennies, some of which are in the possession of Mr. L. A. Lawrence, F.R.C.S., and were shown by the lecturer. Expeditions of war during the reigns of Edward I., Edward III., and Henry V. gave the King's surgeons functions which foreshadowed the beginnings of an Army medical service; the senior of the King's surgeons, the Serjeant Surgeon, was made responsible for supplying a surgical staff and for collecting medical supplies. Prof. Gask illustrated his lecture with lantern slides of drawings from old manuscripts, an interesting exhibit being a surgical instrument case of fine craftmanship, lent by Mr. A. E. Williams, bearing the Royal Tudor Arms and the arms of the Barber-Surgeons Company. This case, it was suggested, may have been presented to Vicary by Henry VIII.

PROPHYLAXIS OF SYMPATHETIC OPHTHALMIA.

Dr. Albert Holdener, assistant in the Bürgerspital at Zug, gives an account[1] of five cases treated in the eye clinic at Zürich, in which sympathetic ophthalmia of the sound eye occurred after early enucleation of an injured eye. In the first case the wounded eye was enucleated 14 days after the injury when the sound eye was completely normal, both to external and to slit-lamp examination. Twenty-two days after the enucleation signs of slight irido-cyclitis supervened, confirmed by the slit lamp, but under energetic treatment with atropine, mercury, and salvarsan it ran a mild course without ever materially affecting the vision, and in ten weeks it was practically well. The second case was that of a man of 22 whose left eye had been blinded by an arrow wound at the age of 10. This eye became irritable and when the patient was admitted to hospital it was in a condition of secondary glaucoma. A trephining was performed and following this an extraction of the lens, but the eye got worse and then at last the patient gave his consent to having it enucleated. After three weeks in hospital the patient was discharged, but 12 days later two punctate spots appeared on Descemet's membrane of the remaining eye. In another fortnight, the signs of sympathetic infection being unmistakable, he was readmitted and intensively treated as in the previous case with such success that he was discharged in a month apparently cured and with normal vision. The third case was that of a man of 28 whose right eye was wounded by the horn of a cow. After three weeks' treatment, including removal of a prolapse of the iris and suturing of a scleral wound, the eye was removed on account of sympathetic danger, which pathological examination proved to be present. At this time there were no abnormal signs in the left eye, but a fortnight after the enucleation, spots on Descemet's membrane were detected which later on increased along with other signs of sympathetic infection. After six weeks' energetic treatment, however, the eye was cured and the patient was discharged with an eye possessing normal vision. These cases enforce the lesson that when an eye receives a wound involving the ciliary body, and more especially when the wound is so serious as to involve total loss of sight in the affected eye, it is dangerous to postpone enucleation even though there may be no sign, detectable by the slit lamp, of commencing infection in the second eye.

[1] Schweiz. med. Woch., Sept. 20th, p. 896.

Further, that when an eye is retained after being blinded by a wound, it is never certain, even many years after the original injury, that sympathetic trouble may not supervene as the result of a slight exciting cause. They also illustrate the encouraging fact that when a timely enucleation of an injured eye has been performed—i.e., before there is any sign even with the slit lamp of the infection having spread to the second eye, even if that eye does later show definite signs of sympathetic cyclitis—the prognosis is far more favourable than when enucleation has been deferred until actual detection of signs of infection in the second eye.

THE BARBITURATES IN LABOUR CASES.

AMYTAL (iso-amylethyl barbiturate) and sodium amytal have, so far as we know, not yet been used as analgesics in confinements in Great Britain. A preliminary report[1] from the Mayo Clinic, therefore, although based on under 50 cases, is valuable. For the results seem to justify further trial and the hope that here is a drug which can be given orally and which, while it affords analgesia, not only does not delay but tends to facilitate the progress of labour. The drug is given in divided doses, grs. 9 being regarded as the maximum dose. Labour is shortened because of the relaxation produced in the soft parts. The drug is to be taken late in the first stage of labour, grs. 3 being given as the first dose. If, in the course of the next four hours, the tone of the muscles is found to be returning and the patient is worried by the uterine contractions, the dose is repeated. The baby appears to be always unaffected by amytal. J. S. Lundy states that after grs. 13 had been given for a Cæsarean section the infant cried on delivery from the uterus.

PARALYSIS OF THE LARYNX.

Sir Felix Semon published in 1881 certain "Clinical Remarks" on paralysis of the larynx; he stated that if there was interference with the recurrent laryngeal nerve, either peripherally or at the centre, the first result of injury was paralysis of the abductor fibres supplying the posterior crico-arytenoid muscles, which open or dilate the glottis; the adductor muscles, constituting the sphincteric group, which close the glottis, survive for a longer time. This observation, known as Semon's law, was the subject of the Semon lecture delivered in the University of London on Nov. 6th by Mr. V. E. Negus. The lecturer devoted his attention to the evidences of comparative anatomy and physiology, for only by examining the origin of lungs, he said, could the facts be approached without confusion. As is well known, some fish swallow air, while others use a specialised alimentary diverticulum for breathing. Lung-fish or dipnoi have lungs, by means of which they are enabled to carry on respiration out of water, and to store up a reserve for use below the surface. In order to protect the lungs a valve is present at the mouth of the air tract in the form of a larynx, and a band of sphincteric muscle is the important constituent of this valve, since it has the vital function of preventing entrance of food or water by virtue of automatic closure. Because of its early origin and vital importance, the function of this band of muscle survives when other functions of the larynx are lost. Semon's law is thus supported and the influence of early origin has its effect in man, even though his larynx has undergone extensive modifications. In amphibians, reptiles, and birds the larynx is provided with lateral cartilages, but the sphincteric muscle still has a vitally important function in closing the glottis, especially in aquatic species. Mammals with a simple type of larynx must close the glottis during deglutition, but herbivorous species and also cetaceans have a special mechanism by means of which liquid or semi-liquid food passes on either side of the spout-like larynx while respiration continues; in animals of this type the sphincteric muscle loses in importance. In man, however, the lateral food channel is inefficient and the larynx must be closed during swallowing. The sphincteric girdle is divided into two paired and one single muscle, but it still serves a protective function; its nerve-supply is resistant to injury because of its mode of origin. There are slight variations in nerve-supply, which do not affect the truth of Semon's law.

To study the dilator muscles, continued Mr. Negus, a start is again made with animals with a simple type of larynx. In the Amazon mud-fish there are no muscles to open the glottis; in the African lung-fish circular fibres corresponding to the pharyngeal constrictors of man serve to open the glottis, while air is forced down the trachea by contraction of these muscle-fibres. Amphibians and reptiles have dilator muscles attached to the tips of the lateral or arytenoid cartilages, and arising from the cricoid ring; these muscles belong to the larynx and open the glottis in the form of a triangle, with the base directed forwards. In mammals and in man the larynx is tilted in order to straighten the air tract and the arytenoid cartilages are necessarily shorter than in lower species, this change leading to backward migration of the dilator fibres. The dilator muscles thereby work with added mechanical advantage; they open the glottis by rotating and pulling apart the arytenoid cartilages, the aperture assuming a triangular shape, with the base behind. Because of later inclusion in the larynx and because of unimportance in primitive types of larynx, the dilator fibres are more vulnerable than those supplying the sphincteric group.

Consideration of the primary functions described appears to explain the reasons underlying Semon's law, and from these Mr. Negus passed on to consider other and secondary functions of the two groups of muscles. A secondary function of the muscles closing the larynx is retention of air in the lungs, and to supplement the action of the sphincteric muscles some animals possess in the larynx valves of a mechanical nature. The dilator muscles also have an independent secondary function—namely, that of holding the glottis open during simultaneous respiration and deglutition, as is well illustrated in whales and dolphins. Neither of these two secondary functions is important in man. During phonation both groups of muscles are in action; the function is not a primary one and has no bearing on the truth of Semon's law, although Semon himself laid stress on it, to the confusion of the issue. Respiratory movements are carried out by mammals and by man, but this function again has no direct bearing on the question. Fixation of the thorax is assisted in arboreal species and in man by closure of the vocal cords. In conclusion, said Mr. Negus, the primary functions of the two groups of muscles must thus be separated from the secondary. They are found to consist of automatic protective closure of vital importance, carried out by the sphincteric group, and automatic opening for respiration, attained by contraction of the abductor or dilator muscles—the latter function being of little

[1] Proc. Staff Meetings, Mayo Clinic, Vol. v., No. 39 p 279.

importance in lower species, but of great importance in man, because of the valvular nature of the glottis and the dangers which result from sucking together of the vocal cords during inspiration. The fibres supplying the dilator or abductor muscles are more vulnerable than those supplying the sphincters, because of the later origin and originally inferior importance of the dilators.

CATHETER FEVER.

THE mechanism of catheter fever has always been something of a mystery. It is liable to occur after the urethra has been injured in persons whose urine is heavily infected with bacteria, but the precise relation of the bacteria to the fever has never been clearly made out. A contribution to the last number of the *Journal of Pathology and Bacteriology* (vol. xxxiii., p. 871), by Mr. F. J. F. Barrington and Dr. H. D. Wright, is an admirable example of collaboration between surgeon and bacteriologist which throws new light on the subject. Briefly, their results show that the blood stream is often invaded by bacteria immediately after the passage of bougies and again immediately after infected urine is passed over the injured surface. This bacteræmia is of very short duration and at the time when the patient feels ill or has an actual rigor the blood is again sterile. Thus, in one case, dilatation after an external urethrotomy was done at 10.40 A.M.; at 10.45 A.M. a blood culture was positive (*B. coli*): urine was first passed at 4.10 P.M. and at 4.20 P.M. the blood again gave *B. coli*. At 5.25 P.M. the patient had a mild rigor, and at 5.30 P.M. the blood was found sterile. In several instances blood cultures were made immediately before operation with negative results, while positive cultures were obtained within five minutes of dilatation. The effects of this bacteræmia do not appear for some time; the rigors are, no doubt, due to the products of destruction either of tissues or of the bacteria themselves, either of which takes time to happen, and when the rigor is going on the blood will probably be found to be sterile. There is therefore no reason to doubt that catheter fever is bacterial in origin and that one may expect to diminish its incidence by reducing to a minimum the injured absorbing surface in the urethra (which is practicable) and controlling the infection of the urine (which is not).

THE DOCTOR'S WIFE.

"DOCTORS have considerable difficulty in getting married," says Joyce Dennys; and we fear this difficulty may be even greater when everyone has read her poignant book on "Mrs. Dose, the Doctor's Wife."[1] Her seven heroines range from Lady Tonsil, who made her husband's reputation, to Emily Bragge, who let the brass plate get dirty. This, the author points out, is "one of the most terrible things a Doctor's Wife can do. I have known Doctor's Wives, when they and their whole households have been laid up with influenza, creep from their sick beds in the early morning and totter out to the gate with the Brasso, and you will often see a Doctor's little Bride, running out with a duster between showers." But most of the tales are about young women like poor little Mrs. Tibia, who do their utmost to please the senior partner's wife and vow that their husband's career shall never suffer by their unguarded behaviour.

"The people gathered round her, and it was obvious to the meanest intelligence that medical attention must be obtained without delay. 'Where is your Husband?' they said, pressing round her and keeping out the fresh air. 'Tell us, where is your Husband?' As a matter of fact, Doctor Tibia was playing golf, but she had learnt her lesson. 'I am not . . . at Liberty . . . to Say,' whispered little Mrs. Tibia, and died."

A similar fate nearly overtook Mrs. Septum, whose husband disliked illness in the home; and no surgeon should neglect the account of her sufferings at the hands of Sir Cadogan Colon, who was always frightfully busy. Even more heartrending, perhaps, were the troubles of Mrs. Base and Mrs. Digit, two school friends whose husbands practised in a small country town and had a very serious quarrel. "The Quarrel was all about a Patient, and one Doctor thought the other Doctor had stolen the Patient away from him. Afterwards the Quarrel became more complicated, but that is how it began." The description of this and other situations shows a sharp insight into medical domestic affairs, and the book is illustrated by the author as amusingly as it is written. The profession will long be grateful for this charming satire, and the wives of practitioners may come to regard it as an "Uncle Tom's Cabin" which draws long-delayed attention to their bondage.

FOG AND ITS MEASUREMENT.

THE fifteenth report[1] of the Atmospheric Pollution Research Committee contains a welcome indication of increasing interest in the purity of the air we breathe. Six new observation stations were set up during the year, making a total of 81 now in operation. The report contains the data for deposit from the air at all these stations, and the results of some special investigations. To take an example, the relation of domestic to industrial smoke, which had been previously examined in London and found to be about 2·5 domestic to 1 industrial, was examined for Glasgow on the same basis, when the ratio for weekdays (excluding Saturdays) was found to be 3·6 domestic to 1 industrial. Of the other special subjects under investigation the measurement of water in fog is perhaps the most interesting. This was commenced some years ago (see the ninth report), when the effect of London fog in obstructing light was being examined. It was realised then that, while the number of solid particles suspended in the air during a fog could be estimated with some degree of accuracy, there was no means available for measuring the amount of suspended water particles. The obstruction of light being due to the effect of both solid and water particles, it became necessary to try to find a method of estimating the latter. A method was devised by Dr. J. S. Owens, based upon the increase of pressure caused by vaporising the suspended water particles.

The measuring instrument consists of two exactly similar vessels side by side and connected only by a U-tube containing liquid paraffin, to act as a pressure gauge. One of these vessels has an attachment at the top to admit air through a calcium chloride drying tube; the other vessel, which has a wide neck, closed by a plug, is filled with the fog-laden air after the instrument has attained the surrounding temperature. Both vessels are at this stage open to the air, the pressure in both being the same. The entrance to each vessel is next closed. We have now in one vessel a sample of fog-laden air, in the other a similar sample of air containing

[1] Mrs. Dose, the Doctor's Wife. Written and illustrated by Joyce Dennys. London: John Lane the Bodley Head Ltd., 1930, pp. 140, 5*s*.

[1] Investigation of Atmospheric Pollution. Report on Observations in the year ended Mar. 31st, 1929. Department of Scientific and Industrial Research. H.M. Stationery Office. Pp. 64. 3*s*. 6*d*.

no liquid particles. The instrument is then placed in a hot water bath, the temperature of which is raised until the manometer shows no further change of pressure, when the difference in pressure between the two vessels gives a measure of the quantity of water drops vaporised, and thus of the quantity present in the fog. For example, if the pressure difference is equivalent to d mm. of mercury, the weight of water drops present in grammes per cubic metre is $289\frac{d}{T}$, T being the absolute temperature of the water bath in degrees Celsius.

Many difficulties were encountered in the operation of this instrument owing chiefly to the difficulty of preventing small leakages. It was, however, tried out with reasonably satisfactory results, and is now under investigation at the National Physical Laboratory, where the results are being compared with those obtained by ordinary gravimetric methods and with those of another form of instrument devised by Kohler. In Kohler's method the fog-laden air is drawn continuously through a tube, where it is warmed until the suspended drops are all evaporated, and the total moisture content, after such evaporation, is measured by a wet and dry bulb hygrometer. A measurement of the humidity before evaporation compared with that after, gives the data for ascertaining the quantity added to the air by evaporation of the drops. Kohler's method obviously depends on the accuracy of the wet and dry bulb hygrometer as a means of estimating the water vapour present in the air.

There is a general impression that the old-time London fog is disappearing, and a comparison of the annual reports shows that there was a fairly steady reduction in the amount of impurity deposited in London from 1915 up to 1921–22, the quantity falling (in round figures) from 400 to 300 tons per square mile. No doubt this resulted in a reduction in the smoke fogs. Since 1921, however, the deposit has remained nearly constant, nor has the amount of suspended sooty matter in London air diminished much during the last ten years. The maximum weekday concentration at Westminster, which usually occurs in the forenoon, has during the whole of this period averaged 150–200 milligrammes per hundred cubic metres. It is not to be assumed, therefore, that the air of London is steadily improving, and that our efforts to purify it may safely be relaxed.

THE VALUE OF MERCUROCHROME.

THE value of mercurochrome as a therapeutic agent formed the subject of a discussion at a meeting of the Section of Therapeutics of the Royal Society of Medicine on Oct. 11th, under the presidency of Dr. Philip Hamill. Apparently one of the chief difficulties experienced by those who wish to estimate its effect lies in the difficulty of obtaining a commercial product of standard composition. Dr J. H. Burn, who has recently tested the toxicity of eight different samples of mercurochrome by injection into mice, was able to produce figures showing a wide range of variation from the theoretical product. At least five of these eight samples were prepared by different firms; analysis showed that while, theoretically, mercurochrome should contain 26·7 per cent. of mercury, 21·3 per cent. of bromine, and no acetate, one product out of the eight contained as much as 40·9 per cent. of mercury, only 11·4 per cent. of bromine, and 7·5 per cent. of acetate, and the remainder contained proportions of these substances which showed wide deviations from the theoretical values. By injecting different quantities of each sample into large numbers of mice he was able to estimate the average lethal dose of each product—that is to say, the number of milligrammes per kilogramme of body weight which would suffice to kill 50 per cent. of the mice injected. He found that the least toxic sample contained the amount of mercury which approximated most nearly to the theoretical value, but that the toxicity of any sample by no means ran parallel to the proportion of mercury. He pointed out that it was impossible to assess the value of mercurochrome until the medical profession had insisted on the production of a standardised preparation by the manufacturers. Sir William Willcox felt that this was an argument for relegating the use of mercurochrome to a time when there was no danger in its use, either to the healthy person or to the patient in dire extremity; but the majority of speakers, if not enthusiastic, were able to award it the tribute of the old Scottish woman to her doctor, and to say that at least it did no harm. Mr. K. Heritage, however, had found it to be of value given intravenously in cases of appendix abscess which ran a swinging temperature after operation. Usually the temperature settled after the first injection, and later rose again, but two or three doses sufficed to bring about complete lysis. It was also effective, if used to wash out the bladder, in cases of intractable chronic cystitis, especially in women, but as a wash for the renal pelvis in pyelitis it had given disappointing results. Some good effects had been observed by Mr. L. C. Rivett from the use of local applications of mercurochrome in chronic cervicitis, but as an intravenous injection for puerperal sepsis he had found it to be disappointing, especially where the infecting organism was a hæmolytic streptococcus; in the presence of a *B. coli* infection there was a greater chance of benefit to the patient from its use. No other outstanding examples of the value of mercurochrome were quoted, and apart from chronic cervicitis, appendicitis with abscess, and cystitis, the feeling of the meeting was apathetic rather than laudatory.

THE Council Dinner of the British Medical Association took place on Tuesday evening last at the Hall of the Association, when Dr. Brackenbury presided over a large company and many distinguished guests. A report of the function will appear next week.

EXHIBITION OF OXFORD BOOKS.—An exhibition of Oxford Books, in connexion with the centenary of the removal of the University Press at Oxford in 1830 from the Clarendon Building to its present site opposite to the Radcliffe Observatory in Walton-street, was opened on Nov. 6th at the Old Court House, Marylebone, W., the new premises of Messrs. John and Edward Bumpus, Ltd. The exhibition will remain open till the end of January, 1931, between the hours of 9 A.M. and 6.30 P.M. on weekdays, with the exception of Saturdays, when it will close at 1 P.M. It shows the developments in printing of the University for the past 100 years and the conditions which prevailed in the early days of Caxton.

CHELSEA CLINICAL SOCIETY.—The annual dinner of this society was held at the Rembrandt Rooms on Oct. 28th under the chairmanship of Mr. F. J. McCann. Ninety-six members and guests attended, the latter including Lord Riddell, Sir Thomas Horder, and the presidents of five kindred medical societies. Letters apologising for their absence were received from Lord Moynihan, Sir John Rose Bradford, Sir H. Curtis Bennett, and the Secretary for Education to the Government of India. The first dinner meeting of the session will be held at the same place on Tuesday, Nov. 18th, when Dr. Anthony Feiling will open a discussion on the Treatment of Headache. All inquiries should be addressed to Mr. Rugg-Gunn, 49, Harley-street, W. 1.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCXI.—NEONATAL ASPHYXIA.

PART II.

IN quite a different category from the cases of blue asphyxia discussed last week are those infants born in a state of

White Asphyxia.

Here the child is in a condition of shock. It is essential to realise this fact, and then the paramount need for warmth and quietness will be realised. No one would treat a case of post-operative shock with very poor respirations by smacking the patient, sprinkling him with cold water or waving his arms about in the movements of artificial respiration. Why, then, should the white baby, who is suffering from a comparable degree of shock, be subjected to such barbarous methods?

Warmth.—Instead, the infant should be separated from the mother by dividing the cord between two pairs of Spencer Wells forceps at fully six inches from the umbilicus. The child must then be warmed. For this purpose there is much to commend dry heat by warm blankets, but in practice it is more convenient to place the child in something which can immediately be prepared—viz., a bath at a temperature of 105° F. Whenever possible this temperature should be checked by a thermometer, for the rubber-gloved hands of the doctor and the skin of the midwife used to very hot water seem to be incapable of appreciating as uncomfortably hot anything less than, say, 110° F., which temperature would be a menace to the infant. If a thermometer is not available, the well-known trick of using the skin of the elbow to test the heat of the water is better than nothing, since any temperature dangerously hot for the infant will be appreciated as unpleasant by this means. Furthermore, the temperature of the water must be maintained at 100° F. to 105° F. This is well worth bearing in mind, since in the stress of other activities it is easily forgotten, and thus one may let the water become dangerously cold for the child.

Extraction of mucus.—The next essential is the thorough clearing of the air passages by a mucus extractor in the manner already specified, and at the risk of tiresome repetition it must be stressed that this step is absolutely necessary and must be performed with care, gentleness, and completeness. The infant's tongue is now held forward, and since it may have to be maintained in this position for some time, a suture passed through the tongue near the tip from side to side would seem to be the most suitable method of achieving this. It must be remembered that time is an important factor in the treatment of these cases, since prolonged apnœa increases the shock from which the infant is suffering. There is little time lost in passing a stitch and thus securing an efficient tractor, since suture materials—preferably fine silk-worm gut—and needles should always be ready to hand. Gentle rhythmic traction on this suture will now serve not only to open up a good airway but also, if performed at intervals of, say, ten seconds, to act as a stimulant to respiration without increasing shock.

Drugs.—It was stated above that the cord should be clamped and divided fully six inches from the umbilicus. This is desirable because it is found that alpha-lobeline injections are of great assistance in the treatment of white asphyxia. Alpha-lobeline can be obtained in solution in ampoules, and of this solution about six minims should be injected into the umbilical vein. A blue bulge is selected and the injection made into this. Then the drug is massaged into the fœtal circulation by compressing the cord from the clamp towards the umbilicus. Another stimulant which may be given instead is Coramine, of which 10 to 15 minims may be injected intramuscularly; in addition brandy may be wiped over the lips, gums, and cheeks in the usual manner.

STIMULATION OF CIRCULATION AND RESPIRATION.

It is found in practice that the result of such treatment as has been described is that the child sometimes begins to gasp and that these gasps recur at gradually lessening intervals. In other cases no improvement seems to take place. The needs of such an infant are obvious. First, there is adequate circulation of the blood; secondly, oxygen is required as a food for the respiratory centre; and thirdly, carbon dioxide is required to stimulate that centre. How can these needs be supplied? A very useful lesson can here be learnt from an experimental animal like the cat. If such a cat dies it may be stated, on the authority of Sir Leonard Hill,[1] that some degree of even peripheral circulation can be maintained by rhythmically compressing, first the abdomen, whereby some blood is squeezed into the right side of the heart, and then (laterally) the thorax. By this latter manœuvre not only is some blood pushed round the pulmonary circulation and thence into the systemic one, but also the recoil of the chest wall may inspire some air into the lungs.

It would seem advisable to attempt to treat the "white asphyxia" case in the same way—namely, by gentle rhythmic compression first of the abdomen and then of the thorax, and with very little force.

Any other manœuvre in the performance of artificial respiration in the accepted sense of the phrase is absolutely contra-indicated as harmfu'. The temptation to perform artificial respiration must be recognised; it is hard to refrain from other movements designed to draw air into the lungs of such an infant when it appears to be dying despite the treatment here detailed. But if the child is going to recover it will do so without the application of what can only be described as ill-judged violence. And it is certain that the extra shock induced by such violence has been the direct cause of death in many infants who otherwise would have survived.

While still considering the white baby's need for an improved circulation, it should be recorded that in cases where the defect is due to raised intracranial pressure, improvement is said to have been obtained by lumbar puncture. This has even been advised as a routine for all such cases, and in my very limited experience of this treatment it has seemed of value. But in general it is probable that the manipulations required would do harm more than enough to counterbalance the good that might be derived, except in carefully selected cases—and the selection is difficult to make.

The next two great needs of the type of baby under consideration are oxygen and carbon dioxide. The

[1] Personal communication to the Hon. Medical Staff of Queen Charlotte's Hospital.

supply of these gases in a suitable manner is a matter of considerable difficulty. With elaborate apparatus this can be overcome, but the practising obstetrician is up against a very difficult problem. In obstetric hospitals it is usual now to find cylinders containing a mixture of 6 (or better, 7) per cent. carbon dioxide in oxygen. A gentle stream of the mixed gases can be obtained from such a cylinder, and by fitting a rubber delivery tube continued by a soft rubber catheter this mixture of gases can be delivered to the child's nasopharynx by passing the catheter along the nostril. It would be a great convenience if there were an apparatus on the market, similar to the Fallopian tube insufflation apparatus, by which carbon dioxide and oxygen in the required proportions could be delivered from a "sparklet" cylinder through a reduction valve, and thus be available for transmission in a manner similar to that above described to the nasopharynx of the white baby. Even then one would be largely dependent on the active respiratory efforts of the child for the oxygenation of the blood circulating as the result either of the natural heart action or of the rhythmic pressure alternately on abdomen and chest as described above; but one would not be entirely dependent on respiration efforts, for the rhythmic pressure would cause at least some disturbance of the gases in the upper respiratory passages, and if a gentle stream of oxygen and carbon dioxide is passing into the nasopharynx a sufficiency of these gases would probably be diffused and absorbed and would be conveyed by the circulating blood, thus acting as a food and as a stimulant to the respiratory and other medullary centres.

In saying that these are the only satisfactory methods by which respiratory exchange can be established, intratracheal insufflation is not forgotten, but is dismissed as being impractical. And with regard to "mouth to mouth" respiration it is my belief that such a manipulation is not only rarely of use, in that it forces air into the child's stomach rather than into its lungs, but is also harmful in that it increases shock. Moreover, when air is thereby caused to enter the child's lungs, harm is sometimes done by rupturing the pulmonary alveoli.

CONCLUSION.

To sum up in the words of Appendix II. of the Medical Research Council's publication on Child Life Investigation,[2] the main points in the treatment of asphyxiated new-born infants are: (1) the avoidance of all violent attempts at resuscitation; (2) absolute rest, warmth, and quiet; (3) the immediate toilet of the air passages so as to remove mucus, meconium, and liquor amnii; (4) the supply of a mixture of oxygen and carbon dioxide; (5) reduction of intrathecal pressure by withdrawal of cerebro-spinal fluid in certain cases, particularly those with signs suggestive of intracranial bleeding.

LESLIE WILLIAMS, M.D., M.S.Lond., F.R.C.S.Eng.,
Surgeon to Out-patients, Queen Charlotte's Hospital.

SPECIAL ARTICLES

THE POSITION OF NURSING: PAST AND PRESENT.

LAST week we announced THE LANCET Commission of Inquiry into conditions of service of the nursing profession, with special reference to the recruitment of suitable student nurses. The Commission is not yet quite complete, but the following have consented to serve:—

Prof. HENRY CLAY, M.A., D.Sc., late Professor of Social Economics in the University of Manchester.

Miss R. E. DARBYSHIRE, R.R.C., Matron, University College Hospital.

Miss L. CLARK, M.B.E., R.R.C., Matron, Whipps Cross Hospital.

Dr. ROBERT HUTCHISON, F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street.

Prof. F. R. FRASER, M.D., F.R.C.P., Professor of Medicine in the University of London, Physician to St. Bartholomew's Hospital.

Mr. A. LISTER HARRISON, J.P., Chairman, Committee of Management, Metropolitan Hospital.

Miss M. D. BROCK, D.Litt., Headmistress, the Mary Datchelor Girls' School.

Mrs. OLIVER STRACHEY, Chairman, Employments Committee, London Society for Women's Service.

Miss EDITH THOMPSON, C.B.E., Member of Council, Bedford College, University of London.

Sir SQUIRE SPRIGGE, M.D., F.R.C.P., the Editor of THE LANCET, with Dr. M. H. KETTLE, an assistant editor, as honorary secretary. The name of the chairman will be announced later. Any organisation or individual wishing to provide evidence for the Commission to consider, or to offer suggestions relating to the improvement of conditions of service of the nursing profession, is asked to communicate with the hon. secretary at THE LANCET offices.

1871.

The interest taken by this journal in the conditions of service of the nursing profession is of no recent date. In 1871 the conditions of night nursing in some London hospitals were investigated by a commissioner representing THE LANCET. The coöperation of several hospitals was enlisted, and visits were paid to the wards between 9 P.M. and 1 A.M. Of the conditions described, those of more permanent interest concern the numerical sufficiency of the staff in relation to the gravity of the cases and the structure of the wards, and the hours of duty. Other points which were important 60 years ago, such as the modes of obtaining additional aid in cases of emergency, or the regulation of the warming and ventilation of the wards at night, have now, with the ubiquity of electric bells, telephones, and central heating arrangements, become only of historic interest. Appended are a few notes on the conditions as then recorded in our columns.

At one hospital "with rather better than 100 beds, we found seven nurses on night duty, not one of whom had yet had a twelvemonth's experience of her work. They were all probationers, and most of them very young. There was not a single fully trained nurse on duty. . . . There is no regular system here for the night supervision of the nurses."

At another hospital the commissioner reports "a state of things which, to our mind, comes very near perfection. The staff consists of 43 nurses and 9 sisters. To every 35 patients (the number contained in a group of two wards) are allotted one sister, four nurses, and one probationer. The four nurses take it in turns to go on night duty—two

on and two off. . . . There is a regular night superintendent who comes on duty every evening at nine o'clock, and who is expected, under ordinary circumstances, to visit each ward in the hospital three times every night. . . . The sisters sleep in small rooms adjoining the wards, and, if an emergency arises, the nurse can call the sister, who takes charge of the case while she (the nurse) goes to fetch the medical officer."

At an infirmary "there were two nurses on night duty, each of whom, with no assistance of any kind, had charge of upwards of 200 patients!"

At another hospital "there are about 200 beds. The nursing staff consists of the matron, six sisters, and sixteen nurses. . . . There are seven night nurses, so that each nurse has the charge, on an average, of 33 patients, but for cases requiring extra attention special nurses are provided. The night nurses come on duty at 10 P.M. and remain on duty till 2 the next afternoon. . . . There is no superintendent of night nursing."

Elsewhere, "the hospital contains 150 beds, and the nursing staff consists of a sister superior, who has entire control, and is assisted by five sisters and 23 nurses and probationers. At the time of our visit there were 11 nurses on night duty. The nurses are by turns on day and night duty, taking a month at each. The night nurses are on duty from 9 P.M. to 9 A.M., and before going into their wards are regaled at 8 P.M. with a substantial meat supper, with tea or beer."

1890.

In 1890 THE LANCET Sanitary Commission made a report on the duties, pay, diet, and recreation of hospital nurses, as deduced from their own testimony. Of the information elicited, mostly from private inquiry, we select the following notes:—

"One of the commonest subjects of remark on the part of my correspondents is the food with which they are supplied. The cooking especially seems often to be faulty. Even when neither quantity nor quality is open to reproach, nurses complain of want of variety in food, and of the absence of fruit even in its season. One writes: 'At times the cooking has been very bad, quite spoiling and wasting good food.' Another says: 'A little more attention to the cooking and serving of food would render it much more appetising without additional expense. The monotony of the diet, and not the quality, is distasteful to a tired nurse' . . . This fault, though undoubtedly existing in some institutions, is as certainly avoided in others. Thus, from another hospital the testimony is: 'The food is good, abundant, and well cooked.'

"But what strikes me as being the most urgent demand is for a shortening of the hours of unrelieved work. . . . I will give the direct testimony of two of my correspondents on this point. The first writes: 'In my opinion the chief evil of the present system of nursing is the long hours the nurses are compelled to be on their feet, and there will be no remedy for that till the day is divided into three parts of eight hours, with three relays of nurses. The night nurses are especially hard worked, for they are on duty 12 hours, and in the medical wards often have not the chance of sitting down for even half an hour; then, after a hard night, have beds to make, washing of patients, dusting, and breakfast to prepare and to give each patient.' Another lady writes: '. . . I have now worked in a hospital for over a year, and my experience is that the whole cry of nurses off duty is "Oh! I am so tired." Should this be? Should a nurse off duty feel so worn out as she does? I quite think that the eight-hour system should be introduced in hospital. Why should not some little bit of the charity which is so freely given to the patients be extended to the nurses?' . . . One of my correspondents says, 'Recreation time is most often spent in resting. Very energetic nurses spend it in studying. I find nothing but the animal instincts for food and rest are left me in my recreation times. I am too tired for any mental exertion' . . . . By a comparison of the papers in my possession I gather that the one holiday of the nurse's long year averages two weeks for a probationer, three for a staff nurse, and four for a sister. A probationer in one hospital where the leave of absence is only ten days writes pathetically: 'The committee will not hear of our having a longer one. When one spends two days in the train, as some of us have to, it leaves us eight days, and to spend about £3 on it seems waste.'

"A rule obtains in some institutions of imposing household drudgery upon nurses. It surely is a very bad economy that employs a valuable expert as a mere housemaid. Why must these ladies be asked to expend their last bit of energy to 'sweep floors, scrub lockers and locker boards, clean brasses, and even keep lavatories in order, to clean lamp globes, and polish head boards?'"

1906–1910.

Early in this century allusions to the nursing profession in our columns are largely concerned with the development of district nursing and the conditions of nursing abroad. Two paragraphs from THE LANCET, 1906, ii., 175, and from 1910, ii., 1456, show that the diet offered and the hours of work exacted were causing public concern.

"*Feeding of Nurses.*—Under the auspices of the National Food Reform Association a conference of hospital matrons was held in Caxton Hall, London, on Nov. 5th to discuss the question of nurses' food in hospitals and similar institutions. . . . The general complaint, as expressed by many representatives, seemed to be the monotony of hospital fare, and many suggestions were made as to the practicability of altering this by adopting some of the French *réchauffé* dishes, and the German methods of cooking vegetables. The chief difficulties apparently lay in the extra thought in planning which would be thrown upon the caterer and upon the intelligence of the cook. But all were agreed that if the result is to be greater vigour in mind and body in the nurses, who are, after all, responsible for carrying out the medical treatment of the patients, then it is certainly worth while attempting to overcome these difficulties. One speaker said she thought the food was not of so much importance as the time taken for meals. In many institutions the nurses have only half an hour for dinner, out of which at least five minutes is taken up in going to and from the wards and dining-room.

"*Nurses and the Public View of their Work.*— . . . The infirmary committee, in the course of a report to the board, called attention to the fact that the infirmary was understaffed, pointing out that a probationer nurse was often in charge of more than one ward—that is, of more than 50 patients. A member of the committee, in moving the adoption of the report, pointed out the severe strain upon the night staff of the hospital and stated that the night nurses had to go without their meals owing to the pressure of their duties. It was proposed that six additional nurses should be appointed, so as to have one on night duty for each ward, which would appear to be a reasonable demand, indeed, the least compatible with safety. Eventually, after some discussion, it was decided to appoint three additional nurses instead of six."

1923.

In 1923 a book appeared[1] which, whether or not the conclusions reached therein find acceptance, sets out the problems requiring solution in clear detail. The book embodies a report of a committee appointed by the Rockefeller Foundation to study "general nursing education with a view to developing a programme for further study and for recommendation of future procedure." The following is an extract from our summary[2] of that section of the work which deals with American

HOSPITAL TRAINING SCHOOLS.

"The development of the hospital training school for nurses constitutes a unique chapter in the history of education. In almost all fields of professional life education has begun on a basis of apprentice training. The first law schools and the first medical schools were the outgrowth of the lawyer's and the physician's office. In nearly all other fields than that of nursing, education has outgrown the apprentice stage and leadership has passed into the hands of independent institutions, organised and endowed for a specifically educational purpose. The training of nurses, on the other hand, is still in the main directed by organisations created and maintained for the care of disease rather than for professional education. The progress which has been accomplished under such anomalous

[1] Nursing and Nursing Education in the United States (Report of the Committee for the Study of Nursing Education). New York: The Macmillan Company. 1923. 15*s*.

[2] THE LANCET, 1923, ii., 1204.

conditions is such as to reflect high credit upon both hospital administrators and the leaders of the nursing profession. Yet the conflict of interests between a policy of hospital administration, which properly aims to care for the sick at a minimum cost, and a policy of nursing education which with equal propriety aims to concentrate a maximum of effective training into a minimum time, is a real and vital one. The fact that the nursing profession fails to attract students in the number, and of the quality desired, strongly suggests that there is some shortcoming in the established avenues of approach thereto. The hospitals themselves, depending as they do so largely upon student nurses for their routine operation, have found themselves seriously handicapped by the small number of well-educated applicants. Inspection of 23 training schools representative of the best current practice in nursing education revealed some interesting points. For example, in some cases theoretic instruction was at fault; in others, ward duties appeared to be largely dictated by the need for hospital service rather than by the educational requirements of the students. This was evidenced by the astonishing irregularity of the time spent on different services by individual students and by the marked deviation between the duties actually performed and those scheduled in the official programme of the course.

The supervision of work in the wards was in certain instances notably inadequate. In only a few brilliantly exceptional cases was the ward work purposefully correlated with theoretical instruction. The lack of an intelligently planned progressive training was obvious in a large number of the hospitals studied, first year students often being found in positions of responsibility for which they were wholly unprepared, while seniors in another ward were repeating an educationally idle and profitless routine. Most striking of all was the factor of time wasted in procedures essential to the conduct of the hospital but of no educational value to the student concerned. Hours and days spent in performing the work of a ward maid, in putting away linen, in sterilising apparatus, in mending rubber gloves, in running errands, long after any important technique involved had become second nature, accounted in one typical hospital operating under the eight-hour system, where this problem was specially studied, for a clear wastage of between one-fourth and one-fifth of the student's working day.

The total amount of time assigned to ward service under the conditions which obtain in many hospitals is, in itself, a fairly complete obstacle to educational achievement. The selected group of hospitals, in this respect above the general average, showed a median day of between 8 and 8·5 hours on ward duty alone, exclusive of all classroom instruction. Irregular, excessive, and unproductive night duty was the rule rather than the exception. Crowded and unattractive living conditions tend, in certain hospitals, to impair the morale of the student body, and an atmosphere of autocratic discipline frequently prevents the development of a psychological atmosphere favourable to effective coöperative effort. It is emphasised that such shortcomings as have been pointed out are not fairly chargeable to deliberate neglect on the hospital authorities or nursing superintendents. In so far as they exist, they are due to the inherent difficulty of adjusting the conflicting claims of hospital management and nursing education, under a system in which nursing education is provided with no independent financial endowments for its specific ends."

In the issue of THE LANCET which contained this summary appeared the following letter from "A Middle-class Patient," reflecting another side:—

"I have just recovered from a troublesome prolonged but not very dangerous illness in which I badly wanted someone to wash me, to bring me my food, to make my bed, and in fact to attend to my physical needs. My doctor wished me to engage a trained nurse, a demand with which I should have been only too happy to comply if it had been possible to provide the extra accommodation, household service, and the meals more elaborate than the usual family ones. I could not face the prospect of having a guest who was entitled to a higher standard of comfort than that of my very modest household. The situation is a familiar one for which I can see no solution. Maybe there is no solution."

1930.

The following are extracts from some of the anonymous letters we have received from nurses following the publication of Dr. E. Carling's letter on Oct. 11th:—

"Though there still exists a large body of good nurses doing magnificent work throughout the country, it would, however, be folly to close our eyes to the fact that our profession is faced with new and urgent problems which call for coöperative effort. We seem to be passing from an era of altruism to one of individualism, and if all the time devoted to condemning the times we live in was devoted to new methods of adapting old machinery to present conditions half our problems would have been solved. Few, except those who have tried it, can realise the sacrifice entailed in working in a small special hospital or sanatorium after the varied and active service experienced in a big training school. Provided one cares sufficiently for the sick, any form of nursing is entirely satisfying and compensates for the almost complete loss of the amenities of a normal social life which a nurse forfeits on entering the profession. But the altruists are passing away and the individualists ask more than nine or ten hours a day devoted to often monotonous service, a thousand restrictions of institutional life, and a salary of about £60 a year. I agree with your correspondent that nursing is a great work, and if that is true, it calls for the finest women, and we shall not get them until the value of their service is openly acknowledged by the medical profession and they are accorded the education, payment, and social status commensurate with the services that they are rendering. At present, I consider the public has a better nursing service than it deserves, but undoubtedly, the service would be improved if a minimum standard of education was demanded for all entrants to the profession and a larger number of fully qualified nurses employed for the actual nursing, instead of training as at present, a large body of probationers eminently unsuited for the great work of nursing. If they were justly remunerated and accorded the professional and social status rightly due to them the women for the vacancies in our hospitals would soon be found."

"The modern educated girl is going to be nobody's 'handmaiden,' and the medical profession having exploited the 'handmaiden' idea of the nursing profession the servile attitude of the nurse has resulted in a loss of social status, which the girl whose brothers are often doctors is not prepared to accept. Medical science would be practically wasted unless there was a profession such as ours prepared to assist in its application. What is that service worth to the medical profession and the community? It has never been properly acknowledged by the former or paid by the latter, and when it is the finest women in the country will fill its ranks. A conference representing the public, the medical profession, and the nursing profession might possibly result in a little more understanding of what we all expect of each other, provided we are all allowed and have the courage to say what we really do expect."

"If the big hospitals still find recruits, but the lesser ones advertise in vain, it seems that there is something wrong with the lesser ones. 'Training' should not be offered by institutions which are not equipped to bring trainees to the State examination standard. In recognised schools conditions of work, teaching, and living have much improved of recent years—the changes for good are being made gradually but continuously, and it seems safe to presume that this improvement will continue. Training schools and lesser hospitals, sanatoria, &c., must coöperate in making a nurse's life satisfying and interesting. Is

it fantastic to suppose that a system could be evolved whereby a large institution could undertake the nursing in small or special 'daughter' institutions? The matron, sisters, and junior grades would be recruited from the large institution (for varying but not too long periods of service in the daughter institution). This might be to everyone's benefit, and in a four years' training it should be possible to make satisfactory arrangements to ensure recognition by the General Nursing Council. In lesser or special Hospitals salaries of £60–70 p.a. (from which contributions to superannuation funds are often deducted) are frequently offered. (Compare the salaries of £40–50 offered in the same institutions to untrained or semi-trained workers.) The hospital or sanatorium may be miles in the country, when even the weekly day off may become an expensive or tedious necessity, whereas annual holidays may not exceed three weeks, but most of all the nurse may be regarded merely as a rather superior domestic servant, and not at all as an intelligent and trained woman able and willing to coöperate in the doctor's lines of treatment. Many hospitals which can offer no advantages of training should be able to attract and offer congenial work to older nurses, many of whom find it increasingly difficult to secure the nursing of acute cases."

The extracts given above, which range over a period of 60 years, indicate that the conditions of nursing service in hospitals have not changed as much or in the same directions as conditions of work in other communities.

To what extent this conservatism is a necessary corollary of lives spent in caring for the sick, and to what extent it is due to other causes, it will be the business of the Commission now appointed to investigate.

STUDIES ON THE ARNETH COUNT.

THE problem of the polymorph had exercised the minds of hæmatologists for many years before J. Arneth[1] in 1904 published his classification of this leucocyte and described its behaviour in infections. His clinical results have received ample confirmation, but no explanation of the marrow reaction nor of the many points in connexion with the nuclear changes in the neutrophil polymorph was attempted until Dr. Eric Ponder, now professor of physiology in New York University, initiated in Edinburgh a series of experimental studies on the Arneth count, which are published from time to time in the *Quarterly Journal of Experimental Physiology*. The early papers, of which the first appeared in 1926, dealt with the relations between phagocytosis and nuclear configuration, and between nuclear configuration and nuclear area, the steady state of the count, the effect of thyroidectomy and the effect of various drugs and extracts on the polynuclear count. Whilst working on the effects of thyroid extract in rabbits, Ponder elucidated the life-history of the polymorph in the blood stream. Other papers of the series by Ponder and his co-workers at the Edinburgh school of physiology included those on experimental tuberculosis in the rabbit, deflection of the count by X rays, the relation between diapedesis and nuclear configuration, the deflection of the count by ultra-violet rays, the relation of the Arneth count to the total polymorph count, and the deviation of the count by various autacoids and animal extracts.

The Count in Surgical Tuberculosis.

The June issue of the *Journal* contains a further series of papers, including one on the Arneth Count in Surgical Tuberculosis in the High Alps, by Walter P. Kennedy and K. Newstead Flint. The authors discuss the Arneth count in cases of joint and bone tuberculosis treated by natural heliotherapy at Leysin. In a previous paper Kennedy and Thompson have shown that ultra-violet rays stimulate the hæmopoietic tissues to pour young polymorphs into the blood stream. Five hundred cases of surgical tuberculosis were examined by one of the authors and a striking difference was observed in the appearance and demeanour of the patients as compared with similar cases treated in this country. The great majority were deeply bronze and, notwithstanding long periods of immobilisation, showed a general muscular development unusual even in healthy persons in Scotland. The end-results were as remarkable—repair of both structure and function being exceedingly good. Blood films were taken from 140 patients—every patient in certain wards—no attempt being made to select patients approaching a cure. Distribution curves of the weighted means of the polynuclear counts in normal persons and tuberculous patients were published by Cooke and Ponder,[2] and upon these frequency polygons a third, that of the Leysin cases, was superimposed. This polygon overlapped the other two and occupied an intermediate position. In other words the Arneth count shows a lesser left-handed deviation in Alpine patients than in patients in Britain. The most obvious explanation is to be found in the different environmental factors, the principal one being that of natural heliotherapy. The authors explain that the action of the sun cannot be merely a stimulation of hæmopoietic function, since that would cause either a more left-handed deviation of the count, or if the removal of polymorphs increased proportionately, a continuation of the status quo. The difference of the frequency polygons is so distinct that this cannot be the case, and the only simple explanation is that the average life of the polymorph is prolonged—i.e., that removal from the circulation is not so rapid. Possibly, too, the sun's action results in more viable leucocytes being formed which, although produced by the marrow under the unfavourable influence of tubercle toxin, compare favourably with those produced under a similar handicap but without the beneficial adjuvant of natural heliotheropy.. It may be that antibodies are formed more readily under Alpine conditions and that vitamin D plays a part in the interactions.

Tissue Surgery and the Arneth Count.

The effect of tissue injury on the Arneth count has been studied by Dr. M. Danzer. of Washington Square, College, New York University, who finds the Arneth count deflected to the left in a variety of conditions, by such substances as thyroxine, colchicine and nucleic acid, by exposure to X rays and ultra-violet light, burning of the skin, crushing of bones or deep parts, as well as in every variety of microbic infection. Rather than postulate that each of these conditions results in stimulation of the marrow in a specific manner peculiar to itself, the author has sought for a particular substance or group of substances produced under all the conditions mentioned and capable of stimulating the marrow, to the presence and action of which the deflection of the count might be ascribed. The injection of extracts of muscle, brain, liver, and testis caused, in five hours, a marked left-handed deflection comparable with the deflection following the injection of 1 mg. of nucleic acid. A striking result was obtained by the injection of washed hæmolysed red corpuscles taken from and injected subcutaneously or intravenously into the same rabbit. In five hours the total leucocytes were double the previous numbers and the polynuclear count more

[1] Deut. med. Woch., 1904, xxx., 54.

[2] Cooke, W. E., and Ponder, E.: The Polynuclear Count, London, 1927, p. 69.

markedly deflected than with any other substance. Deproteinised extracts produced no deflection of the count. It is a reasonable assumption that the leucopoietic stimuli in these cases are proteins or substances allied to proteins. If they are proteins it is quite possible that they require to be broken down or otherwise transformed in the body before they can produce their effect because the deflection of the count by these tissue extracts is more slowly produced than by nucleic acid or thyroid extract. Except for the delay of three hours, the results are, however, exactly similar. The effect of destruction of tissues in vivo was next studied. Most anæsthetics—chloroform, ether, and chloralose—deflect the count, but it was found that ethyl urethane had no effect on it in rabbits. Under this anæsthetic muscle was destroyed by crushing, bones were fractured, and extensive superficial burns produced. The polynuclear count was deflected in exactly the same manner as in the former experiments. The author suggests that the continual and normal breakdown of tissue in the body is sufficient to provide a stimulus for the continual and normal output of polymorphs by the marrow.

Irradiated Ergosterol and the Count.

In the last paper of the series, in which Dr. D. R. Climenko reports on the deflection of the count by irradiated ergosterol, the experiments of Kennedy and Thompson are repeated, and the effects of injection of irradiated ergosterol in maize oil, separately and in conjunction with ultra-violet light, are studied in relation to the Arneth count and the calcium content of the blood. The result of ten minutes' exposure to the mercury-vapour lamp was the deflection of the count in the manner described by Kennedy and Thompson plus an appreciable but temporary increase in the blood calcium. The increase in the calcium content was not of the same order as that produced by large doses of irradiated ergosterol, but the deflection of the count was closely comparable in both series of experiments. The combination of irradiated ergosterol and direct radiation produced an additive effect on the blood calcium, an increase from 11·2 mg. to 17·4 mg. in 24 hours being noted. In the controls no deflection of the count nor alteration in the blood calcium level was produced either by filtered ultra-violet light or by non-irradiated ergosterol. These studies on the Arneth count have elucidated many points in connexion with the nucleus of the polymorph and led to a better understanding of the nature of the marrow reaction. The importance to practical medicine is apparent and illustrates once again the advantages of coöperation between physiologists and clinicians.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

JUVENILE EMPLOYMENT.

AFTER a long experimental period of juvenile advisory committees, the Scottish Education Department have issued a model constitution for such committees: they should have a chairman appointed directly by the Ministry, four representatives of the local education authority (or authorities) concerned, four teachers nominated by the Educational Institute for Scotland (representative of primary, advanced division, and secondary schools), six employers' representatives, six workpeople's representatives, and four other persons interested in questions relating to the employment and welfare of boys and girls. This constitution is variable according to local necessity. The committee's duties will be: (1) the advising of boys and girls between school-leaving age and the age of 18 on the selection of a suitable career; (2) rendering of assistance to boys and girls in obtaining employment; (3) the supervision of the boys or girls during the early stages of their industrial life as may be found necessary. The school-leaving cards must contain: a statement of the educational standard attained by the child, an expression of opinion by the head or other teacher on the child's aptitude for the work desired, and any material particulars of the child's medical history. Need for after-care or industrial supervision should be indicated by the head teacher, and reports should be furnished on all children about to leave school.

It is expected that this will result in a closer coöperation of the labour authorities and the education authorities. Conferences in schools are suggested.

THE PROGENY TEST.

Mr. A. D. Buchanan Smith, of the Animal Breeding Research Department of the University of Edinburgh, made some important points in a recent lecture on the progeny test. Now that milk is growing in use as a food, quantity becomes very important, and, in selecting good milkers, breeders must take account of the father as well as of the mother of his cows. Mr. Smith said that of the bulls used in the pedigree dairy herds of this country 85 per cent. were sent off to the butcher before their daughters came into milk. The only way that the value of a dairy cow could be estimated was by measuring the milk she produced, and until the daughters were in milk it was next to impossible to get any idea of the value of the bull they were using. This value was proved when the yields of the daughter of a bull were better than the yields of the dams of the daughters, allowing for the fact that a heifer's yield was only four-fifths of her mature yield.

RADIOLOGY AT GLASGOW.

The formal opening of the new radiological department at the Western Infirmary is an event of major importance to the Glasgow medical school. The Infirmary was one of the first institutions to make use of X rays for diagnostic purposes, and its work in ten years has increased from 6000 to over 19,000 exposures a year. The situation of the Infirmary is one of the finest in Scotland, and the new department benefits by this fact. It forms an important unit in the hospital's organisation as the national radium centre. Dr. C. O. Hawthorne, who gave an address at the opening ceremony, spoke of certain tendencies in present-day medicine. Bedside studies were being reinforced by laboratory investigations, but it was on these studies that the great bodies of fact and doctrine rested. The notion that a patient's ills and requirements could be determined by some form of scientific test made in a laboratory by an observer who had never seen the sick man was only less fantastic than the claim that a film of blood on a blotting paper could reveal the pathological disturbances of which the patient was the victim. He then sketched the enormous improvement in methods and results from the steady development in the delicacy of apparatus. On the uses of radium he spoke with scientific moderation. Whatever might be its therapeutical possibilities, radium was, he said, an element with dangerous qualities, and was not safe out of the hands of a specially trained and highly competent staff. Its value was undoubted, but like all single

and powerful remedies it had excited hopes out of all proportion to its present importance.

DR. WOODBURN MORISON'S APPOINTMENT.

There is widespread regret that Dr. Woodburn Morison should have left Edinburgh to accept a chair of radiology in London, for it is felt that the new department at the Royal Infirmary had grown up with him from the first elements of the building plan. Equipped on a scale hitherto unknown to Scottish institutions, he knew it with the intimacy that is possible only to the designer and the executive architect. Full details were given in this column when the Duke of York opened the department four years ago, and these need not be repeated. It was at a cost of £52,000 that Edinburgh redeemed the reproach that an X ray installation must be sought in a noisome cellar. I recently took an English friend over every section of the department, and he was immensely struck with the many signs of the directive intelligence that a department with so many dangerous machines demands. Prof. Morison seemed to keep alive in his brain every piece of apparatus under his care, and the enthusiasm of his officers reflected his own. All his friends in Edinburgh wish him success in his new appointment.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

GALWAY BOARD OF HEALTH.

LAST week Mr. A. P. Delaney, one of the inspectors of the Department of Local Government and Public Health, held an inquiry into the manner in which the County Galway Board of Health performed its duties. The immediate cause of the inquiry was the refusal of the Board of Health to appoint an assistant to the county medical officer of health. The former county tuberculosis officer had recently been appointed county medical officer of health, and the Board had failed to provide him with an assistant. At the inquiry the secretary of the Board of Health stated that the only reason for the refusal of the Board was the desire to save the county from being saddled with expenses it could ill afford. The proposed plan was only the beginning of a scheme which would land the county in bankruptcy. He read an opinion given by the medical staff of Galway Central Hospital which expressed disapproval of the proposed scheme. There were 367 schools in the county, and to carry out a scheme of school inspection and treatment would cost over £10,000 a year. As an alternative poor children should be treated by the dispensary doctors, and the children of the rich could have treatment provided at the expense of the parents. As regards tuberculosis, the county medical officer should attend the various tuberculosis dispensaries throughout the country as part of his duties, and the staff of the Central Hospital would be responsible for the care of the County Sanatorium; or, as an alternative, the care of the tuberculosis dispensaries should be entrusted to the dispensary doctors. Dr. B. O'Beirne, county medical officer of health, stated that it was absolutely necessary that an assistant should be appointed. Since his appointment as county medical officer of health he had been unable to attend at the six tuberculosis dispensaries scattered through the county, and they had been neglected. Prof. T. Walsh, a former chairman of the Board of Health, gave evidence in support of the opinion expressed by himself and his colleagues at the Galway Central Hospital. He said that the existing machinery was adequate, and it was only a question of coördinating it. To inspect schools was useless unless treatment was provided for all defective scholars. An effective scheme would require the services of four or five additional doctors, and he did not think that this expense was justified. At the moment the great difficulty in County Galway was poverty. The inquiry concluded after further evidence on behalf of the Board of Health.

ULSTER MEDICAL SOCIETY.

At the second meeting of the session on Oct. 30th, with Mr. Henry Hanna, the President, in the chair, Dr. R. H. Hunter made an appeal for the study of the history of medicine, and suggested that the society should try to foster an interest in this subject by opening each meeting with a short paper on some phase of this subject. He then read such a paper, on the Treatment of Wounds in the Dark Ages. At first, he said, suppuration was induced in all wounds to rid the body of evil humours, and the wound was kept open by tubes and setons. Theodoric, in 1266, tried to introduce the washing of wounds with white wine and dressing with lint soaked in wine, and so to obtain healing "by adhesions." This method never became popular, and the older method remained popular until the sixteenth century, when the margins of the wound were drawn together and kept in place with a thick paste. Until Lister introduced his antiseptic technique mediæval methods were not finally abandoned. Mr. P. T. Crymble then read a paper on the results of 36 consecutive cases of gastric ulcer treated by gastrectomy. There were three operation deaths and one subsequent death. The follow-up showed the following results: very good, 21; good, 4; fair, 2; no reply, 5. In three cases the ulcer developed in the presence of a gastro-enterostomy. Mr. Crymble brought forward a number of arguments in favour of gastrectomy for gastric ulcer: (1) it reduces acidity; (2) the ulcer-bearing area is removed; (3) it offers the safest and easiest means of dealing directly with an adherent ulcer; (4) not only is the palpable ulcer removed, but the excised portion is often found to be the seat of gastritis or a second ulcer; (5) the danger of leaving a cancerous ulcer is eliminated; (6) the danger of jejunal ulcer is almost completely eliminated; (7) the ultimate results are very good, and the patient with a small stomach can lead an ordinary life. In 33 of the cases a retrocolic end-to-side gastro-jejunostomy was done, and in three an antecolic end-to-side gastro-jejunostomy.

THE LADY CHICHESTER HOSPITAL.—This institution for women and children at Hove is this year keeping the twenty-fifth anniversary of its establishment. It was the first hospital in England for patients seeking treatment on a purely voluntary basis for early nervous and borderland maladies. Patients, who are admitted simply upon a medical recommendation, pay according to their means up to a maximum of £3 10s. per week, but no one is refused admission on the ground of inability to pay. There are 53 beds; the average annual admission-rate is 175; and of 100 consecutive cases 73 were discharged fit to return to their ordinary life. A new annexe has been provided for the accommodation of patients of both sexes in connexion with an out-patient department for early nervous and borderland cases at the Sussex County Hospital, Brighton, and an appeal is being made for the means to pay off debt and defray the cost of the new accommodation.

PUBLIC HEALTH SERVICES

MENTAL HOSPITAL REPORTS.

The DEVON MENTAL HOSPITAL publishes an illustrated report with photographs of some of the industries which keep the patients employed. There were 1311 patients on the register at the end of last year, and the shortage of accommodation on the female side became acute. The recovery-rate was 43·04 per cent., the highest figure for 30 years. The death-rate was 8 per cent.—a slight increase accounted for by 10 deaths from malignant disease and 6 from epilepsy. Post-mortem examinations were made on 65·3 per cent. of the cases. There was no typhoid or paratyphoid and these diseases seem to have been eradicated; routine inoculations have, therefore, been discontinued. There were four cases of dysentery, and 12 patients suffering from general paralysis were treated with malaria. Four of them have been discharged and three show improvement. In three cases an unsuccessful attempt was made to induce malaria with sporozoites from the salivary glands of the mosquito, sent in blood serum through the post. Ten of the cases received tryparsamide injections in addition to malaria inoculations. The results were encouraging. The total of paralytic patients treated by malaria is now 40, and the medical superintendent gives an account of one successful juvenile case. Three cases of piles and one of varicose veins were treated by injection. The visiting surgeon examined 68 patients and performed 30 major operations. The visiting ophthalmic surgeon examined 83 cases, and the dental surgeon saw 822 patients at his fortnightly visits. Ultra-violet light treatment was given to 36 patients with benefit. It does not, however, seem to suit epileptics or agitated melancholics. The consulting radiologist made 56 examinations. The laboratory was busy with the usual investigations, and the out-patient clinic at Exeter increased its annual attendance from 63 to 130. To give adequate service both to new patients and after-care cases the fortnightly sessions will have to be changed to weekly ones. A water-aerating plant was purchased in June, and in six months had effected a saving of £8 on the purchase of syphons of soda and lemonade. An average of 139 patients daily had parole within the estate, while 50 more were allowed outside and 25 were taken out by friends for short periods. The open-door system and club-ward system are also freely adopted. Practically all the printing required in the hospital is done in the shop, and other patients are employed on bookbinding, weaving, net-, mat-, brush-, basket-, and rug-making, knitting, and raffia work. Nurses are now required to sign an agreement to take a three years' course of systematic instruction which qualifies them to sit for the examinations of the General Nursing Council. One sister attained her double qualification last year, three nurses and one attendant passed the final G.N.C. examination, and ten nurses and two attendants the final R.M.P.A. examination. There is urgent need for better accommodation for the nursing staff.

The report of the Asylums' Committee for the CITY OF BIRMINGHAM states that there were 2730 patients under their care at Winson Green on March 31st, 1930. The recovery-rate for the preceding 12 months was 45 per cent.; 48 of the 77 patients discharged recovered were allowed out on a month's preliminary trial, 32 of them with financial help. The death-rate was 7·35 per cent., and post-mortem examinations were made in 93 per cent. of the deaths. The general health was satisfactory, except for an influenza epidemic in the spring. Two male patients and one female were suffering from tuberculosis at the end of the year, and one attendant was attacked with diphtheria; otherwise there was no infectious disease. The visiting ear, nose and throat specialist examined 162 patients, and found chronic septic conditions in the majority. The visiting gynæcologist examined 92 women, many of whom needed treatment for inflammatory conditions or displacements. The visiting dentist examined all new admissions. The results of treating chronic focal sepsis have continued satisfactory. Protein therapy by means of T.A.B. vaccine was given to 52 patients, and nine were treated by malaria for general paralysis. Artificial sunlight was used during the winter. Useful employment was provided for 65·5 per cent. of the patients, and parole was freely granted; 60 per cent. of the staff hold the R.M.P.A. certificate.

At RUBERY HILL AND HOLLYMOOR there were 1373 patients on Dec. 31st, 1929. The recovery-rate was 40·7 per cent., and the death-rate 7·73 per cent. Autopsies were carried out in 49·2 per cent. of the deaths. Influenza took a toll inside as well as outside the hospital during the early part of the year, and a large number of patients suffered from the epidemic. Only two patients are known to be suffering from tuberculosis, and intestinal diseases have been entirely absent. Routine examinations of new admissions often reveal the fact that the patients have suffered from intestinal infection, and this factor is believed to reduce the resistance to septic infections. A small epidemic of diphtheria occurred in the summer, and was soon traced to a carrier. The dairy herd has twice been tested for tuberculosis with no positive results. During the year five attendants and 19 nurses passed their final R.M.P.A. examination, bringing the total certificated to 86 attendants and 66 nurses.

The MONYHULL COLONY for feeble-minded and epileptic children had 1206 cases in residence on March 31st last. There was a death-rate of 12·7 per 1000, about half the deaths being due to epilepsy; 12 cases of tuberculosis have been under treatment and, apart from mild influenza, there has been little infectious disease. Leave of absence was granted to 1367 patients during the year, a larger number than formerly, and on the whole the leave regulations were fairly well observed. As in all institutions of this kind, there is acute pressure of accommodation, which is bound to interfere to some extent with the classification of patients. The dental condition of the colonists is now very satisfactory, and the work of the dental surgeon is showing its good effects in better health generally. All the workshops were busily occupied during the year, and the industries were developed as far as possible. On an average 394 men and 460 women were regularly employed, and over 36,000 articles were made and 65,000 repaired. Pathological investigations are made for the colony at the Hollymoor laboratory. During the year eight nurses passed the final examination of the R.M.P.A., so that there are now 32 nurses and 35 attendants certificated or State registered.

At the RESIDENTIAL SCHOOL there were 329 patients on March 31st. The average age of the children on admission is between 5 and 10. It is much better that they should come early, but there has been a certain amount of congestion in the junior classes. The children are under daily medical observations in the home, and a consulting staff is available when required. The dental surgeon examined all new cases, and makes periodical inspections. Two nurses attained their R.M.P.A. certificate during the year, bringing the total to 11 certificated or registered.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 1ST, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 87 (last week 86); scarlet fever, 2301; diphtheria, 1520; enteric fever, 42; pneumonia, 698; puerperal

fever, 48; puerperal pyrexia, 102; cerebro-spinal fever, 11; acute poliomyelitis, 9; acute polio-encephalitis, 3; encephalitis lethargica, 12; dysentery, 5; ophthalmia neonatorum, 106. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 4th–5th was as follows:—Small-pox, 183 under treatment, 3 under observation (last week 172 together); scarlet fever, 1803; diphtheria, 2198; enteric fever, 17; measles, 90; whooping-cough, 105; puerperal fever, 22 (plus 10 babies); encephalitis lethargica, 121; "other diseases," 43. At St. Margaret's Hospital there were 11 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was 1 death from small-pox, 3 (0) from enteric fever, 15 (1) from measles, 6 (1) from scarlet fever, 10 (1) from whooping-cough, 32 (2) from diphtheria, 62 (20) from diarrhœa and enteritis under two years, and 41 (9) from influenza. The figures in parentheses are those for London itself.

The fatal case of small-pox was reported from Stepney Met. Boro. Bristol and Hull each reported 3 deaths from measles; Worcester, Birmingham, and York each 2. Four fatal cases of scarlet fever were reported from Leeds. Liverpool reported 4 deaths from diphtheria, Manchester and Dewsbury each 3. Diarrhœa accounted for 6 deaths at Liverpool, 3 each at Birmingham and Nottingham. Birmingham also reported 7 deaths from influenza.

The number of stillbirths notified during the week was 261, corresponding to a rate of 40 per 1000 births, including 47 in London.

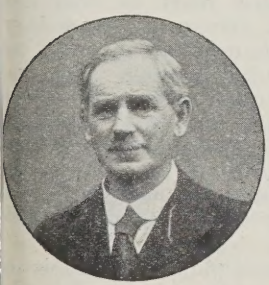
DEATH FROM SMALL-POX.

The fatal case of small-pox reported in the metropolitan borough of Stepney was that of a dock labourer, aged 58 years, who was admitted to St. George-in-the-East Hospital on July 8th, and removed on Aug. 4th to Joyce Green Hospital, where he died on Oct. 31st. Dr. J. M. Browne, medical officer of health for Stepney, informs us that the cause of death was certified as (1*a*) myocarditis; (2) small-pox. The man had been vaccinated in infancy. There was no autopsy.

OBITUARY

ROBERT LINDSAY, L.D.S. Edin.

Mr. Robert Lindsay, who died on Nov. 4th, had been the dental secretary of the British Dental Association for 11 years, and his loss both to the Association and to the dental profession as a whole is a severe one. Before taking up this appointment he was in practice in Edinburgh, where he had held a teaching post in connexion with the Edinburgh Dental School. As the first full-time dental secretary of the association he found scope for his powers of organisation, his great energy, and his detailed knowledge of every phase of dental work.



MR. ROBERT LINDSAY.

The passage of the Dentists Act, 1921, created many difficulties, for it legalised the position of the large number of unqualified practitioners. The Dentists Register established by the newly formed Dental Board included both qualified and unqualified dentists, and the latter were in a large majority. This Act, though plainly inevitable, was bitterly resented by many qualified dentists, and a split was threatened in the ranks of the British Dental Association. Lindsay performed valuable work in averting such dissension, and the fact that the Association surmounted this difficulty and went on increasing in strength was largely due to his shrewd practical sense. The institution of panel dentistry as an additional benefit under the National Health Insurance Act was another change which has been of great value to the community as a whole, but has created delicate problems calling for tact and persuasiveness. It was necessary to establish a scale of fees acceptable both to the insurance societies and the dental profession. The difficulties of negotiation were enhanced by the fact that the societies had to deal both with the British Dental Association, representing the qualified dentists, and with the various bodies to which the unqualified but registered practitioners belonged. In the end these difficulties were surmounted, though not easily. "It would be hard to speak too highly of the work which Lindsay carried out in this connexion," writes a colleague. "Much of it was done behind the scenes, and the full extent of his labours is known only to a few. But the dental profession has cause to be deeply grateful to him. He was an excellent speaker and his retentive memory enabled him to deal with a complicated mass of details without a note. Though a complete master of the innumerable details constantly arising in his work, yet he had a broad outlook and always took a statesmanlike view of any problem under discussion. Personally, he was a man of simple tastes. Austerity and kindness were happily blended. His criticisms could sometimes be pungent but were always devoid of malice. He served the British Dental Association with single-minded loyalty, and by all its members and by many others outside its ranks his death will be deeply mourned."

CHRISTIAAN EIJKMAN, M.D.

Prof. Eijkman, who has died at Utrecht, laid many of the foundations of our present knowledge of deficiency diseases, and shared with Sir Gowland Hopkins the Nobel Prize for Medicine in 1929.

The son of a schoolmaster, Eijkman was born in 1858, at Nijberk, a small town on the Zuyder Zee. He began his studies in 1875 at the University of Amsterdam, and was for some years assistant to the professor of physiology there. In 1883 he joined the colonial army in the Dutch East Indies, but he was invalided home two years later and resumed his laboratory work, this time as a bacteriologist. In 1886 he returned to the Dutch East Indies as a member of a study commission on beri-beri, which at that time was raging in the Dutch colonial army and navy. The ætiology of this disease was then obscure and as the medical world had been hypnotised by Pasteur and his followers into thinking of disease in terms of bacteria, it is not surprising that this commission came to the conclusion that beri-beri must be an infectious disease. While his colleagues on the commission returned home, Eijkman remained in Batavia as director of the new laboratory for bacteriology and pathology and took charge also of the medical school for native doctors.

Eijkman's original research in connexion with beri-beri began in a curiously accidental way. He wished to carry out certain investigations on fowls, and in order to economise on their food he fed them

on scraps from the wards of the military hospital to which he was attached. On these scraps, which consisted chiefly of cooked, polished rice, the fowls developed paralyses, whose nature was at first obscure. A clue thereto was unintentionally given by a newly appointed director of the hospital, who refused to let Eijkman feed his fowls any longer on scraps from the wards. Henceforward they were fed on gaba (rice still in the husks) and on this diet they recovered. Eijkman's identification of this polyneuritis gallinarum with the beri-beri of human beings was at first generally scorned or ignored, but about 1896, after much painstaking research in coöperation with Dr. Grijns and Dr. Voderman, he came to the firm conclusion that a diet of over-milled rice was the chief cause both of the polyneuritis of fowls and of the beri-beri of human beings. The term "partial hunger" was given to this condition.

Other investigations into morbid conditions of the blood in the tropics led Eijkman, in the early 'nineties, to reject some of the prevalent conceptions of the nature of tropical anæmia, which at that time was held to be a nosological unit. He also challenged the assumption that human metabolism varied greatly with the different climates. He showed that the metabolism of the human body is practically identical in the tropics and in cold climates; and he came to the conclusion that acclimatisation does not mean a fundamental change in metabolism, but immunisation to a new group of infectious diseases with which the newcomer to the tropics had not previously been in contact. Among the more important research which he carried out in later years was his study of fermentation tests and the demonstration of the presence of *Bacillus coli* in water (Eijkman's test). After being invalided home in 1896 Eijkman was appointed professor of hygiene at the University of Utrecht, and he held this post till 1928, when he was in his seventieth year.

CONSTANTIN von MONAKOW.

THE death of Prof. von Monakow at Zürich at the age of 77 removes one of the founders of modern neurology. As a young asylum doctor he was attracted to the organic substratum of sensation and movement at a time when little was known even of the tracts in the brain-stem. His first work was, therefore, directed to a study of the relations of the thalamus with the higher and lower centres. For this purpose he devised the method, which in his hands gave fruitful results, of cutting tracts or removing nuclei in newly born animals and examining the brain after some months of growth to find what parts of it had failed to develop. In this way he was able to demonstrate the relationship of the various nuclei of the thalamus to different parts of the cortex, of the mesial fillet to the nuclei of the posterior columns, of the striæ acusticæ to the lateral fillet, and of the red nucleus to the rubrospinal tract. He was also the first to demonstrate clearly the relationship of the optic tract to the external geniculate body.

These early researches, while bringing him fame, set Monakow in opposition to much of the teaching of the day. From anatomical study of the brain-stem he proceeded to a study of localisation in the cerebral cortex. In this work he had to rely largely on human clinico-pathological material from which it was more difficult to reach clear-cut conclusions, but the philosophic bent of his mind made him dissent from the current tendency towards localising each function of the cortex in a circumscribed area. For him there were, indeed, areas in which the combined action of lower centres was integrated, but his knowledge of comparative anatomy and physiology enabled him to see the chronological basis of this integration. With the development of the fore-brain more and more powers of integration were relegated to it, and in lesions or disease of the cortex those which had come latest were usually the first to be lost. This chronological basis was assumed by him not only in his work on aphasia but in relation to his much discussed theory of diaschisis. This theory was an attempt to explain the widespread and severe initial loss of function which follows sudden damage to the nervous system. According to Monakow's theory the damage to the centre split or tore apart the constituent elements of a function, destroying their integration. This disturbance at first abolished the functions of the individual elements, and these were later re-established according to the chronological basis already mentioned. This theory formed the basis of an attack on the theories of cerebral localisation current at the time which was launched in his book "Die Lokalisation im Grosshirn," published in 1914.

Monakow's theories of the function of the brain tended towards a humoral basis. This was already noticeable in his theory of diaschisis, according to which the nutrition rather than the function of the lower centres was disturbed by a lesion of a higher centre. Later, he became impressed by the influence of the ductless glands on the activity of nerve-cells, and he suggested the theory that mental diseases might be due to degenerations of the choroid plexus which allowed metabolic poisons to pass through it into the cerebro-spinal fluid and thence into the brain substance. During his later years he was also engaged in formulating a system of psychology, individual and based on his own earlier work, but influenced to some extent by Bergson. This was embodied along with much other material in a book published in 1928, in association with Mourgue, "Introduction biologique à l'étude de la neurologie et de psychopathologie," a book which, in the phrase of a reviewer, "orients the neurologist and psychopathologist and provokes and compels thought."

An original thinker whose philosophic habit of thought was restrained by an untiring zeal in the quest of facts, Monakow was a constant stimulus to his students and associates. He was active in forming first a Zürich neurological and psychiatric society, and later a Swiss neurological association; in 1917, in spite of the difficulties of publication due to the war, he inaugurated the *Archives suisses de neurologie et psychiatrie* which he edited up to his death. Our memory of him is of a tall, big-hearted, kindly man, remarkably modest, in spite of his commanding position in Swiss neurology, and very appreciative of the recognition which he received from British neurologists.

WEST BROMWICH HOSPITAL.—The board of management have declined to establish a contributory fund on the ground that it desires to maintain the entirely voluntary nature of the hospital. At the annual meeting it was stated, on behalf of the medical staff, that if a contributory scheme were started they would have to ask for payment. The number of in-patients treated last year was 1373; there were 17,932 out-patients. The in-patients stayed on the average 27·10 days; the average cost of each was £8 19*s.* 2*d.*, and the average cost per occupied bed £104 15*s.* 1*d.*, as compared with £113 0*s.* 6*d.* in the preceding year.

CORRESPONDENCE

ELECTRO-SURGERY.

To the Editor of THE LANCET.

SIR,—Your leading article of Nov. 1st might give the impression that electro-surgery has made little progress in London. As a matter of fact in my own hospital practice, in that of my colleague at the Middlesex Hospital, Mr. Gordon Taylor, and doubtless at other hospitals, the electric needle has definitely replaced the scalpel for many categories of operation. For breast and mouth surgery it is at present indispensable, and you allowed me the privilege of advocating diathermy for carcinoma of the breast in your columns as far back as May, 1927. Mr. Anderson, who has done such good work in Dundee in pioneering the method, appears not to have used the diathermy needle for abdominal surgery. It will be found, in my opinion, a most satisfactory instrument for gastrectomy, lessening hæmorrhage, both operative and post-operative, from the divided mucous membrane and—what is much more important—reducing shock to a minimum. I feel bound to record, in regard to gastrectomy, my dissent from Lord Moynihan's recent statement that the technique of the operation cannot be improved upon. The use of diathermy alters the whole aspect of the post-operative period and does away with the need for special measures, such as transfusion and intravenous saline, which were required in its first days.

It would be regrettable, and very unfair to our own manufacturers, if the impression got abroad that good surgical work can be done only with a very expensive imported machine. Where direct current is available the old small Schall machine, the cost of which is very moderate, does excellent work. There are several quite efficient and not expensive alternating current machines both of English and continental make. Hospitals installing the method—and every hospital must shortly do so—should choose their machine by actual trial of competing machines in the operating theatre, should avoid the temptations of mere costliness and unnecessary ultra-refinement, and should give the preference, efficiency being equal, to an English machine.

I am, Sir, yours faithfully,

W. SAMPSON HANDLEY.

Harley-street, W., Nov. 7th, 1930.

A MEDICAL SERVICE FOR THE NATION.

To the Editor of THE LANCET.

SIR,—I am afraid that in spite of Mr. Layton's trouble I remain unconvinced. I recognise that his contention that social service is valuable is a logical result of his belief that at birth all are equal. But this assertion does not become a fact by mere assertion. I would ask Mr. Layton if he considers that the farmer believes that at birth all calves are equal? Why does the farmer spend large sums in breeding stock from animals of proved superiority in milk yielding? I am told by those who have observed under the rather rare conditions in this country that there is considerable difference at the seventh day in the expression, movements, cry, and behaviour of the child of slum parentage and a child of the "quality," nursed side by side from birth under similar conditions. What about Galton's researches into the inheritance of genius? Surely Mendelian factors have some influence in human heredity. Admitted there are few data for the human race, but they have been shown to play a part in the blood groups.

The survival of the fittest still holds good for the human race, though civilisation has done a good deal to upset the balance, but in general terms the successful adaptation to life depends on a balanced moral, mental, and physical equipment. The successive waves of invasion into the aristocracy described by Disraeli depended on the efforts of the best equipped members of the lower castes who had inherited the most valuable genes from both parents. On investigation it would be found that the other members of those families remained at their original level.

The factor of chance cannot be disregarded and must bring about some exceptions to the general rule. But in contradistinction to Mr. Layton I think it must be agreed that some individuals inherit a better equipment than others and that the progress of the race depends on these more fortunate persons. They should not be denied the opportunity of helping their more unfortunate fellows, but on the other hand they should not be hampered or crippled by demands for a luxury social service. If everyone is reduced to a general dead level in the endeavour to eliminate class distinctions the progress of the race will be endangered. As Bicket says in Galsworthy's "White Monkey," life would be a frost if the world were reduced to the level of a pound a day. The better stock would be discouraged at the deprivation of opportunities for further progress, and the poorer stock would be deprived of all responsibility or any further incentive for improvement.

I am, Sir, yours faithfully,

Bristol, Nov. 8th, 1930. FRANK BODMAN.

MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—There can be little doubt that the arrangement of the medical curriculum is to those in whose hands it rests an unending source of difficulty. So much to be learnt and, relatively, so little time in which it is to be taught. The outcome of the labours of these persons in authority must, from the nature of things, be rather the result of the sifting of those opinions to which they have access than the conclusions derived from first-hand experience. From this it would reasonably appear that while the advice of those who teach is easily obtained and readily given the great mass of those who are taught remain inarticulate. The students, lacking authoritative representatives, are unable to give coherent expression to their views. Consequently, the balance of opinion available to those who arrange the curriculum is unevenly struck. The opinion of experience is, admittedly, more valuable than that of inexperience. The young, notoriously, do not know what is good for them. Yet the knowledge that the student possesses of his own capabilities, desires, and ambitions renders his opinion deserving of a certain consideration. You will, therefore, perhaps allow some of your valuable space for this comment upon existing conditions.

It is obvious that, as the scope of the medical curriculum widens, compensation must be found either in increased duration of studentship or in greater concentration of study within the allotted

time. As the period of training has already been lengthened to the limits of financial endurance, a process of intensified study is the only issue out of the difficulty. This correction for the inevitable increase in medical knowledge works itself out along the following lines. For five or six years lectures and demonstrations jostle one another in close competition, and the immediate study of the patient recedes further and further into the background. The student, in his endeavour to achieve examination success, resorts to the highly vicious process of cramming. As the capacity of the mind is limited, a fairly complete knowledge of a few subjects is replaced by a smattering of knowledge of several subjects. This is, in effect, a redistribution of the available mental energy as the number of subjects to be learnt, grows. But the increase of the number of subjects carries with it an additional evil. It results in the dissipation of interest. The student's mind becomes the repository of half-digested knowledge, for the complete digestion of which there no longer exists the intellectual appetite.

The position is a deadlock. However desirable it may be for the student to be conversant with, for example, anything more than the broadest outlines of psychological or preventive medicine, the fact remains that he is incapable of absorbing more than a certain amount of knowledge in a given time. And this amount is limited, in the main, by natural ability and interest. The present lack of time enjoyed by the student for the exploitation of those lines of interest awakened by his work, allied with the consciousness that he must be continually pressing on to some other part of the syllabus, is one of the most unfortunate results of the increasing curriculum.

The solution of these problems is difficult. It is hard to see how the syllabus can be cut down or the course of training lengthened. There does, however, seem to be one weakness in the system, the correction of which would possibly result in a saving of time, and, almost certainly, in a greater maintenance of interest. The marked segmentation of the medical training into the three examination stages has two undesirable sequelæ. First, until he commences clinical work, the student tends to forget to what end he is studying any particular subject. The danger of this is increased in virtue of the fact that he is taught by specialists at every stage. The biology course may be instanced as an example of this. Here the teachers are biologists interested in experimental biology rather than in medicine. Inevitably, the student's interest becomes misdirected. He becomes temporarily a biologist in embryo, rather than a doctor in embryo. What should be the motive medical idea is for the time being forgotten. And so on, throughout the whole of the early training, in the absence of any medical thought or atmosphere, the student loses sight of the fact that he is supposed to be building a firm basis on which to found his medical knowledge. Secondly, the system results in a certain unnecessary re-covering of old ground. Anatomy and surgical anatomy do not enjoy the economical relationship to one another that would seem justifiable and desirable; similarly, medicine and physiology, pathology and histology. In fact, so frequently has this failing been pointed out that its exemplification requires no further elaboration here.

The cure lies in the application in this sphere of the basic idea of Lord Moynihan's Toronto address. A closer coördination of the teaching of the various component parts of the medical curriculum is needed. This can only be achieved by the institution of a collateral system of studying the various subjects. Under such circumstances the student would not lose sight of his ultimate goal and would almost certainly find the work easier to learn. Collateral study would satisfy the student that he was, all the time, acquiring information that would be useful to him, and by so doing would keep alive his original enthusiasm. This enthusiasm dies because the contact with actual medicine, to which the student has so long looked forward, is made too late in the training. To study the preliminary subjects in terms of the desired knowledge would stimulate interest in both of them.

I am, Sir, yours faithfully,

London, W., Oct. 27th, 1930. DONALD BATEMAN.

INJECTION TREATMENT OF SIMPLE GANGLION.

To the Editor of THE LANCET.

SIR,—Mr. P. McEvedy, who described in your issue of Oct. 25th (p. 902) a method of treating simple ganglion by injection with sodium morrhuate, might be interested in the following case.

A healthy young man consulted me for a swelling of his left pinna which for all the world looked like a hæmatoma, but there was no history of even a slight injury and transillumination showed that the contents were not opaque. With a minute injection into the skin of sterinovo, I aspirated the cyst, withdrawing a yellow fluid, which was found to be sterile and contained a few red blood corpuscles, evidently serum. Three or four days later the swelling had reformed. This time I adopted the same procedure, only after aspiration I injected, through the same needle, 1 c.cm. of quinine urethane — just half the amount of the fluid aspirated. The condition was quite painless except for a little "tingling irritation" after two or three days, and in less than ten days the pinna was completely restored to its normal shape.

I am, Sir, yours faithfully,

WRIGHT LAMBERT, M.R.C.S., L.D.S.

Brentwood, Essex, Nov. 8th, 1930.

HÆMATOPOIETIC PROPERTIES OF DRIED MILK.

To the Editor of THE LANCET.

SIR,—I am grateful to Dr. Taylor for affording me this opportunity to make clear what might appear an omission. Dr. Helen McKay's exceedingly interesting paper described the administration of quantities of iron—up to nine grains or more per diem per infant—that amount to medicinal doses. My investigation was primarily concerned with a possible nutritional deficiency, and the means of remedying it.

Cow's milk contains little more than half the milk sugar of human milk. This deficiency is well recognised and is made good in infant feeding by the addition of sugar or by the use of a humanised food. The work I cited indicates that cow's milk is also deficient in iron. Many practitioners would, I think, wish to make good that deficiency also, since it only amounts to one-thirtieth grain per pint, though they might hesitate to give several grains of iron and ammonium citrate as a daily routine to an infant. My own experiments were solely intended to discover whether this could be achieved by drying the iron in with the milk.

The downward trend of the hæmoglobin content in the rats towards the end of the experiment is what is normally observed with increasing age. At the end of the experiment the animals were more than half-way

towards maturity. A similar fall is known to occur in human blood.

I am, Sir, yours faithfully,

A. L. BACHARACH.

Glaxo Research Laboratory, Osnaburgh-street, N.W., Nov. 10th, 1930.

IRRADIATION OF GERM-CELLS AND FŒTUS.

To the Editor of THE LANCET.

SIR,—In your leading article of Oct. 11th (p. 806) you have overlooked the work of Dr. Leopold Goldstein, of Philadelphia. Among those of Murphy, Archenheim, Stettner, Quin, Driessen, Lacassagne, and Seynsche his name seems to me worthy of mention. I append a list of his contributions to the literature of this subject.

I am, Sir, yours faithfully,

HYMAN I. GOLDSTEIN.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

Protection of Dogs Bill.

IN the House of Commons on Wednesday, Nov. 5th, Sir R. GOWER introduced the Protection of Dogs Bill, a measure to prohibit the vivisection of dogs. The Bill was supported by Lieut.-Colonel Moore, Mr. Freeman, Lieut.-Commander Kenworthy, and Mr. Markham.

School Attendance Bill.

On Thursday, Nov. 6th, Sir C. TREVELYAN (President of the Board of Education), in moving the second reading of the Education (School Attendance) Bill, asked what could be more extremely important than giving another year of school life to 500,000 children? The object of the present great reorganisation of the educational system was to ensure a real education between the ages of 11 and 15 in schools devoted to that purpose. In general there was agreement as to most of the principles of that reorganisation. A definite and important part of the reorganisation proposed by the Hadow Committee, and which was being prepared for now by the local education authorities, was the raising of the school leaving age. In the educational world there was hardly an effective challenge to that proposal with the exception of Lord Eustace Percy, the former President of the Board of Education. What was good enough for the children of the well-to-do was surely good enough for the children of the working-classes. If this Bill was passed the change could be affected in April, 1931. The Bill was more liberal to the claimants for maintenance grants than the proposals made by the Committee of the Local Education Authorities in the past summer. The parents who claimed these grants would be required to make a simple declaration of income. That declaration could be challenged in Court, and, if false, the parent could be severely punished. In fixing the income limit he had taken a standard which was sufficiently high to include all wage-earning families where by any stretch of argument the need could be regarded as considerable. This Bill was the charter of the average child. Much of the most vigorous talent lay dormant until 14 or 15. More and more it was upon the average child that the future of the nation depended.

Lord EUSTACE PERCY, in moving the rejection of the Bill, said that one of the admitted needs of the present day was that by every possible means they should maintain the purchasing power of the masses of the people and maintain the employing part of what he might call the employing classes. The country had got to the stage where any reduction of income of any class in the community was reflected, either in the reduction of purchasing power, or in the reduction of employing power. According to Sir C. Trevelyan's figures—which he (Lord E. Percy) thought were an under-estimate—after paying the maintenance allowances to the parents they were reducing the weekly budget of some 300,000 families in this country by 7*s.* per week; and in the second place they were increasing the taxation on the employing classes by at least £7,000,000 to £9,000,000 a year. This would lead to more unemployment.

EFFECT ON SCHOOL CHILDREN'S HEALTH.

Dr. FORGAN, supporting the Bill, said he would like to refer to its effect on the health of the children of the nation. It was generally admitted that the school medical service had been responsible for considerable improvement in the health of the children. Unfortunately from the school leaving age of 14 until 16, a period in the lives of boys and girls when they became young men and young women and were specially in need of medical attention and supervision, there was no State provision for the care of the health of these young persons. The fact that this Bill would extend the school medical service to some 500,000 boys and girls would be a positive benefit which would mean in time to come a direct financial saving. From the medical point of view he heartily supported the measure.

Dr. VERNON DAVIES said that he was a great supporter of education, but he recognised that education had two distinct purposes—first, to educate the child so as to make him a decent intelligent citizen, and secondly to fit him to earn his living. If these children were going to be kept at school for an extra year were they and the community generally going to benefit? Could the workers and the industries of the country afford this Bill? The Government were the custodians of the public purse, and members of Parliament were not sent to that House to squander money. He submitted that at the present time the country could not afford the expense entailed by this measure.

Dr. HASTINGS said that in a comparatively few years they had provided for every child in the elementary schools not only medical inspection, but medical treatment as well. In some cases that medical treatment was admirable, but in other cases it was not so good. The result of this inspection had been to show that there was a tremendous amount of disease among the children. He had looked up the figures in the report of the Chief Medical Officer of the Board of Education, and in 1928 over 20 per cent. of the children had defects needing treatment other than for teeth, and 67·5 per cent. needed dental attention. There could be no doubt about the admirable results of the treatment that had been given. In his report for 1923 the Chief Medical Officer took up the question of deafness, and in London the amount of deafness in 10 years among children in elementary schools had decreased to one half. The report gave details showing that even better results were being obtained in Cambridge, Exeter, and elsewhere. But children coming to school at the age of 5 showed no decrease in the amount of ear disease. When the children took

their place in industry they had the panel medical service, and that had been of value from a public health point of view, and had provided medical treatment for a large class of people who never before obtained it. His point was that between the termination of treatment by the school medical service and the commencement of that given by the national insurance service there was a gap. That gap came at a very critical time in the life of the child when he earned poor wages and sometimes no wages at all. A child at 14 or 15 did not realise the importance of the early treatment of disease, and frequently put things off as long as he could. He had asked the President of the Board of Education that day whether it was not possible to do something to close that gap by passing on the records obtained from the inspection of school-children to the panel committee. It seemed to him that if they increased the school age, even by a year, they would do a great deal for public health by adding an extra year's preventive treatment to the lives of the great mass of the nation's children.

After further debate,

Mr. MORGAN JONES (Parliamentary Secretary to the Board of Education), replying to the debate, said that he was confident that if the measure was accepted by the House the nation would be able to secure that the coming generation, strong in physique and alert in intelligence, would be able to carry the national burden in the days of difficulty and complexity, which no doubt lay before us, on to a prosperity greater perhaps than we now dared hope.

The Bill was read a second time by 294 votes to 227 —Government majority 67.

HOUSE OF COMMONS.

WEDNESDAY, NOVEMBER 5TH.

Experiments on Living Animals.

Mr. BROMLEY asked the Home Secretary if he had had his attention drawn to a recent case where a science teacher at Haverthwaite illustrated a lesson to his pupils by the vivisection of a cat, which he had chloroformed for the purpose; whether the teacher had a licence to vivisect, and also if the school where the incident took place was a registered place under the Act of 1876; and if he would take steps to prevent such practices.—Mr. SHORT replied: My hon. friend has been misinformed; there was no vivisection in this case. The animal was painlessly killed, and next day its body was brought to school and dissected. Such proceedings are not within the Act and require no licence, and my right hon. friend has no power to take any action in the matter.

An Overdose of Medinal.

Viscount ELMLEY asked the Home Secretary whether he proposed to take any action with regard to the evidence given at a recent inquest in Liverpool on a woman who had died from an overdose of medinal.—Mr. CLYNES replied: Under the existing law I have no power to take any action in this matter, but the Government have under consideration the question of introducing legislation to give effect to the recommendations of the recent Committee on the Poisons and Pharmacy Acts, one of which was to the effect that power be given to prohibit by rule the sale of certain poisons, except on a medical prescription.

Housing Progress.

Mr. DAY asked the Minister of Health the number of houses completed in England and Wales during the year ended to the last convenient date, giving the number of these houses separately that were completed in the London area.—Mr. GREENWOOD replied: The number of houses of a rateable value not exceeding £78 (£105 in the Metropolitan Police District) completed during the year ended March 31st, 1930, in England and Wales was 202,060, of which 5718 were completed in the County of London, or on estates of the London County Council outside the county boundary.

Sir KINGSLEY WOOD asked the Minister of Health the number of houses finished under the various Housing Acts each quarter since June 1929; and the number of houses during the same period erected without State assistance.—Mr. GREENWOOD replied: The following statement gives the desired particulars so far as State-assisted houses in England and Wales are concerned:—

Quarter ended—	Housing, Town Planning &c. Act—		Housing (Financial Provisions) Act, 1924.
	1919.	1923.	
Sept. 30th, 1929 ..	18	39,227	17,730
Dec. 31st, ,, ..	14	—	14,507
March 31st, 1930 ..	—	—	10,571
June 30th, ,, ..	—	—	11,351
Sept. 30th, ,, ..	—	—	14,881

Returns as to houses erected without State assistance are obtained half-yearly only, to the end of March and September respectively. The number of such houses of a rateable value not exceeding £78 (or £105 in the Metropolitan Police District) erected during the six months ended September, 1929, was 38,298, and during the six months ended in March last, 53,393. Complete figures for the six months ended in September last are not yet available.

Sir KINGSLEY WOOD asked the Minister of Health to give the latest returns showing the progress under the Housing (Rural Workers) Act, 1926.—Mr. GREENWOOD replied: Up to the end of June last, the latest date to which complete information is at present available, assistance had been promised under the Housing (Rural Workers) Act, 1926, in respect of 3308 dwellings in England and Wales. Work had been finished on 2206 dwellings, and was in progress at that date on a further 818 dwellings.

Mr. RAMSBOTHAM asked the Minister of Health whether the housing shortage was definitely at an end; and, if not, where such shortage existed in acute form.—Mr. GREENWOOD replied: It is common knowledge that there is still a widespread shortage of working-class houses. I shall be better able to judge its local incidence in presence of the results of the survey prescribed by Section 25 of the Act of 1930, to be made by local authorities.

Slum-clearance Schemes.

Sir KINGSLEY WOOD asked the Minister of Health the number of slum-clearance schemes since March 31st, 1930, to the last convenient date, confirmed, completed and in course of execution at the end of such period, respectively.—Mr. GREENWOOD replied: At June 30th, 1930 (the latest date to which complete figures are at present available), 71 slum-clearance schemes remained to be completed in England and Wales. Two such schemes were completed between March 31st, 1930, and June 30th, 1930, and none was confirmed during that period.

Sir KINGSLEY WOOD asked the Minister of Health the number of buildings which had since March 31st, 1930, been acquired by local authorities in connexion with approved slum-clearance schemes.—Mr. GREENWOOD replied: The number acquired in England and Wales between March 31st, 1930, and June 30th, 1930, the latest date to which complete figures are at present available, was 463.

Factory Conditions in East London.

Major NATHAN asked the Home Secretary whether he had received the report of the chief inspector of factories as to conditions in many workshops and factories in the boot and shoe industry in East London. —Mr. CLYNES replied: Recent reports by the factory inspectors on all the factories and workshops now working confirm the previous inquiries, the result of which I gave in my reply to my hon. friend the Member for Frome on June 5th last. They show

that it is only in a very small proportion of the works—about 10 out of a total of 172—that poor or bad conditions prevailed. About one half are definitely reported on as good, while the remainder reach on the whole a satisfactory standard. In all cases where irregularities were found action has been taken to enforce the Act, and the conditions are reported to have much improved.

School Medical Records.

Dr. HASTINGS asked the President of the Board of Education whether in view of the importance of medical records in connexion with the prevention and cure of disease, he was willing to authorise local education committees to transfer to local insurance committees, when so requested, copies of the medical records of children leaving school.—Sir CHARLES TREVELYAN replied: In view of the administrative difficulties involved, and the interval which is likely generally to elapse between the age at which a child is last medically inspected in school and the age at which the first application for medical benefit is made, I am not at present satisfied that I should be justified in advising local education authorities to make so important a departure from the existing practice. In this connexion I would remind my hon. friend that the Board have always impressed upon local education authorities the importance of securing that the school medical records are treated as strictly confidential.

Dr. HASTINGS: Have any applications been received for these records?

Sir C. TREVELYAN: I am not aware of any.

MONDAY, NOV. 10TH.

Preliminary Opium Conference.

Mr. MANDER asked the Home Secretary if he could make any statement as to the progress and the proposals made at the preliminary opium conference recently opened in London.—Mr. CLYNES replied: I am informed that considerable progress has been made with the consideration of the matters referred to the preliminary conference, and that it is hoped to submit a report in the course of a few days.

Use of Poison Gas in Warfare.

Mr. GRAHAM WHITE asked the Secretary for Foreign Affairs the names of States which had formally pledged themselves, by treaty or otherwise, to abstain in future from the use in war of asphyxiating or poisonous gases or liquids or similar noxious substances; and the names of States, if any, which had further pledged themselves to coöperate in the prevention by international action of the use of such substances in warfare.—Mr. HENDERSON replied: Twenty-seven States have both signed and ratified the Geneva Protocol of June 17th, 1925. Nineteen other States have signed, or otherwise acceded to, this Protocol, but have not yet ratified it. All States bound by the Protocol undertake to exert every effort to induce other States to accede to it. The following States have both signed and ratified the Geneva Protocol of June 17th, 1925: Austria, Belgium, United Kingdom of Great Britain and Northern Ireland, Canada, Australia, New Zealand, Union of South Africa, Irish Free State, India, China, Denmark, Egypt, Finland, France, Germany, Italy, Liberia, Persia, Poland, Portugal, Roumania, Spain, Union of Soviet Socialist Republics, Sweden, Turkey, Venezuela, Yugoslavia. The following have signed, or otherwise acceded, but have not yet ratified: Abyssinia, United States of America, Brazil, Bulgaria, Chile, Czecho-Slovakia, Estonia, Greece, Japan, Latvia, Lithuania, Luxembourg, Netherlands (including the Netherlands Indies, Surinam, and Curacao), Nicaragua, Norway, Salvador, Siam, Switzerland, Uruguay.

War Pensioners and Institutional Treatment.

Mr. D. G. SOMERVILLE asked the Minister of Pensions the number of men wounded in the war for whom his department still provided institutional treatment.—Mr. ROBERTS replied: The average number of disabled ex-Service officers and men (apart from cases of mental disease in mental hospitals) for whom my department is providing institutional treatment, whether for wounds or diseases, is, in round figures, 4000. The number of cases of wounds requiring treatment cannot be separately stated, but about one-fourth of the whole number are in hospital for surgical treatment.

Closing of Bellahouston Hospital.

Mr. STEPHEN asked the Minister of Pensions when he proposed to close Bellahouston Hospital, Glasgow; and what steps he proposed to take to provide for the large number of ex-Service men in Glasgow and the West of Scotland in need of hospital treatment.—Mr. ROBERTS replied: After careful consideration I have decided that Bellahouston Hospital cannot justifiably be maintained beyond a date early in the new year, so that the premises may be handed back to the Red Cross and the necessary reinstatements completed by the date of the expiry of the lease. I have arranged with the committee of Erskine House for the use of that hospital for the type of case at present treated at Bellahouston. The patients will be under the care of the same surgeon as heretofore. I have also made arrangements with the Glasgow Royal Infirmary for the immediate admission of any case requiring urgent emergency treatment. All out-patients will be treated at the Glasgow Area Clinic.

Ophthalmic Treatment of School-children.

Mr. DAY asked the President of the Board of Education the number of children provided with spectacles in England and Wales under the arrangement made by education authorities for the 12 months ended to the last convenient date; and the number of authorities in England and Wales who had not the services of an experienced oculist.—Sir CHARLES TREVELYAN replied: Some 140,000 children were provided with spectacles during the year 1929, under arrangements made by education authorities in England and Wales. All local education authorities have the services of an experienced oculist, except the authority for the Isles of Scilly, where the circumstances are, of course, exceptional.

Diphtheria in Kohat.

Colonel HOWARD-BURY asked the Secretary for India whether he was aware that diphtheria had been prevalent in Kohat for a year, and that the disease had been almost entirely confined to British officers and their families, and whether any steps had been taken to trace the disease to its source and to prevent its future recurrence.—Mr. WEDGWOOD BENN replied: I have not received any information on the subject, but will inquire if the hon. Member so desires.

TUESDAY, NOV. 11TH.

Irish Hospitals Sweepstake.

Sir WILLIAM DAVISON asked the Chancellor of the Exchequer whether his attention had been called to the sums of money leaving this country for investment in the Irish Free State sweepstake; and whether he had in contemplation the issue of premium bonds or other similar device to secure the retention of such moneys in this country.—Mr. PETHICK-LAWRENCE (Financial Secretary to the Treasury) replied: The answer to both parts of the question is in the negative.

Sir WILLIAM DAVISON asked if the hon. gentleman was aware that hundreds of thousands of pounds were leaving this country for the Irish Free State in this connexion, that a much larger sweepstake was contemplated, and if he would not do something to meet the sporting instincts of the country in the way of premium bonds which would be both an investment and a lottery.

MEDICINE AND THE LAW.

Revivalism and Orthopædics.

THE possibility of unfortunate results following a faith-healing campaign was considered by the Stoke-on-Trent City Council at the end of last month. Many thousands of people in the potteries district are said to have been drawn to revivalist meetings conducted locally by Pastor Edward Jeffreys, a Welsh evangelist. At these meetings, it has been stated, crippled children for whose treatment the city corporation is responsible have been dealt with in a manner likely to retard their recovery. It was alleged, for example, that three child patients undergoing treatment for tuberculous disease of the spine were taken out of the frames on which they had been fixed. A boy suffering from shortening of the leg, who had been fitted at the hospital with a raised boot and calliper to prevent spinal distortion, had the calliper removed. Allegations of this nature were set out in a letter addressed to the medical officer of health (Dr. A. Wotherspoon) by Mr. W. Mitchell Smith, orthopædic surgeon to the North Staffordshire Cripples' Hospital. The letter was brought to the notice of the health committee of the council. After further consideration of the matter by the general purposes committee, the town clerk was instructed to inform Pastor Jeffreys that, while the corporation had no desire to interfere with his meetings, an undertaking would be required of him that he would not so deal in future with the children for whom the corporation was responsible. Pastor Jeffreys, on the other hand, is reported to have denied that any splints or irons have been removed by him from anyone attending his revival meetings; he claims that no one has left his meetings in any worse condition than that in which they came. He is said to have asserted in the course of an address "We say that the people are healed through Jesus Christ and the doctors don't like it," and to have claimed that there have been outstanding cases of healing which no doctor can dispute.

The City Council seems to be on firm ground in interfering on behalf of the children entrusted to its care. The case of adults, who are free to adopt any treatment they wish, is different. Those who have experience on the one hand of the remarkable results of faith healing, and on the other hand of the inevitable disappointments, will know that the warnings of the medical profession are not to be dismissed as the mere outcome of religious scepticism and professional prejudice.

MEDICAL NEWS

University of London.

Prof. G. E. Gask, director of the surgical unit at St. Bartholomew's Hospital, has been elected Dean of the Faculty of Medicine for 1930–32.

As a result of the M.D. examination in July the University medal in medicine has been awarded to Thomas Anwyl Davies, of St. Thomas's Hospital, and in pathology to Dorothy Stuart Russell, of the London Hospital.

C. L. Oakley, M.B., has been appointed Graham Scholar in Pathology at University College Hospital for two years.

Application is invited for the Geoffrey Duveen travelling studentship in oto-rhino-laryngology, of the value of £450. Candidates must be medical graduates of the University, and should apply in prescribed form to the Academic Registrar before Dec. 31st.

The Nathaniel Rogers prize for 1931, valued at £100, is offered to registered medical practitioners for an essay on Filtrable Viruses as a Cause of Disease in Man. Particulars are obtainable from the Academic Registrar.

Five lectures on Diseases of Bacteria will be given by Dr. F. W. Twort, F.R.S., superintendent of the Brown Animal Sanatory Institution, in the theatre of the Royal College of Surgeons, Lincoln's Inn-fields, London, W.C., at 4 P.M., on Dec. 1st, 3rd, 5th, 8th, and 10th.

Medico-Chirurgical Society of Edinburgh.

The following are the office-bearers for 1929–30:—President: Prof. G. Lovell Gulland. Vice-Presidents: Mr. J. W. Dowden, Dr. E. F. Armour, and Dr. John Bowie. Councillors: Dr. C. W. Somerville, Dr. W. Fordyce, Dr. H. G. Langwill, Dr. Alex. Goodall, Dr. F. K. Kerr, Dr. Norman Carmichael, Dr. H. Maitland Moir, and Mr. A. Pirie Watson. Treasurer: Dr. John Orr. Secretaries: Dr. H. L. Watson Wemyss and Mr. F. E. Jardine. Editor of Transactions: Dr. Fergus Hewat.

Royal College of Physicians of Edinburgh.

A quarterly meeting of the College was held on Nov. 4th with Sir Norman Walker, the President, in the chair. Dr. Henry Leonard Wallace (Edinburgh) and Dr. William Brown (Aberdeen) were introduced and took their seats as Fellows. Dr. Earle Macbeth Watson (Ontario), Dr. William Archibald Hain (Bournemouth), Dr. Agnes Rose Macgregor (Edinburgh), and Dr. James Davidson (Edinburgh) were elected to the Fellowship. The Hill Pattison-Struthers bursary in anatomy and physiology was awarded to Maurice Goldfar, and the Hill Pattison-Struthers bursary in clinical medicine to Robert Leitch Allan.

Royal Faculty of Physicians and Surgeons of Glasgow.

The following will be the office-bearers for the coming year:—President: Dr. John F. Fergus. Visitor: Mr. R. Barclay Ness. Treasurer: Dr. J. H. MacDonald. Librarian: Dr. E. H. L. Oliphant. Councillors: Mr. G. H. Edington (representative of the Faculty on the General Medical Council), Dr. Andrew Alison, Dr. R. M. Buchanan, Mr. J. G. Connal, Dr. Carstairs Douglas, Dr. John Gracie, Dr. John Henderson, Mr. W. D. Macfarlane, Dr. Souttar McKendrick, Mr. Ferguson Mackenzie, and Prof. Archibald Young.

Socialist Medical Association.

At a recent meeting it was decided to form an organisation with this title. The following officers and committee were elected:—President: Mr. Somerville Hastings, M.S., M.P. Trustees: Dr. Hector Munro and Dr. V. H. Rutherford. Treasurer: Dr. Alfred Welply. Secretary: Dr. C. W. Brook. Executive Committee: Dr. Alfred Salter, M.P., Dr. R. Forgan, M.P., Miss Esther Rickards, M.S., L.C.C., Dr. Caroline Maule, Dr. Frank Bushnell, Dr. S. W. Jeger, Dr. A. V. R. Menon, Dr. J. Grant Morrin, Dr. J. Powell-Evans, and Dr. M. Rose.

Finances of University College Hospital.

On Thursday last week Prince George presided at a dinner at the Mansion House in aid of the funds of this hospital, when the amount collected, including the result of the dinner appeal, was £6500. It was stated that in the last ten years the number of beds had increased from 322 to 540, which had swollen the annual expenditure by £16,000. In the current year the expenditure will be £112,000, of which £12,000 will have to be provided by further voluntary contributions.

University of Aberdeen.

Sir Arthur Keith, conservator of the museum of the Royal College of Surgeons of England, has been elected Rector of the University of Aberdeen. Sir Arthur stood as an independent candidate and defeated Mr. John Buchan, M.P., who was nominated as a Conservative.

Society of Apothecaries of London.

Lieut.-Colonel C. T. Samman, the Master of the Society, will preside at a dinner to be held on Tuesday next, Nov. 18th, when the honorary freedom of the Society will be conferred on Mr. Arthur Greenwood, Minister of Health. The gold medal for pharmacy will be awarded to Prof. Ernest Fourneau, of the Pasteur Institute, Paris.

Extension of Edinburgh Infirmary.

An appeal is being made for £500,000 for the extension of this great hospital. The principal objects of the enlargement are the reduction of the waiting lists of between 2000 and 3000 names, mostly of persons needing surgical treatment, the provision of a combined obstetrical and gynæcological hospital of 240 beds, and a nurses' home.

An Association of Hospital Contributory Schemes.

At a conference of representatives of hospital contributory schemes at Birmingham last week it was decided to establish an association for the coördination of such efforts. Besides being a clearing-house for information, the new body will make suggestions, assist associated schemes in cases of difficulty, and be at the disposal of seekers for information when contemplating the establishment of new schemes.

A Montgomeryshire War Memorial Hospital.

A war memorial hospital for the county of Montgomery was opened last week at Llandiloes by Miss Jones, daughter of Sir Robert Jones.

South-Eastern Hospital for Children.

At the recent dinner at Merchant Taylors' Hall on behalf of this hospital £11,000 was raised.

A Railwaymen's Cot.

The Bishop of Portsmouth recently dedicated a cot in the Southern Railway Servants' Orphanage at Woking presented by the Portsmouth district committee of the institution.

Stannington Sanatorium.

A new operating theatre and X ray room have been opened at the Philipson Children's Sanatorium at Stannington, Northumberland, which contains 300 poor children.

Swindon Victoria Hospital.

Last week Lady Lansdowne opened a new wing of the Swindon and North Wilts. Victoria Hospital. Two new wards of 40 beds have been added.

Manchester Royal Infirmary Nurses' Home.

The Lord Mayor of Manchester last week opened the new nurses' home of this hospital. It will now be possible to increase the staff by 72 nurses and to establish an average working week of 56 hours. The building, which has cost £140,000, of which £60,000 remains to be raised, provides 168 bed-sitting-rooms, a number of corporate sitting-rooms, writing rooms, and a large recreation hall, the cost of which, £10,653, was raised by the nurses themselves.

"Friends of Aldershot Hospital."

Under this title an organisation has been formed for rendering personal service to Aldershot Hospital. The only financial obligation is the payment of sixpence a year, and the members register their names for sewing, mending, gardening, egg-collecting, taking patients home on discharge, and any kind of simple job for the hospital that may be required.

Enlargement of Harrow Hospital.

Miss Diana Churchill, daughter of Mr. Winston Churchill, recently opened new nurses' quarters at this hospital to which the name of Florence Nightingale has been given. Other extensive additions are in progress. An operating theatre, an X ray department, new wards for general patients, and private wards for paying patients are among these additions. The hospital is warmed by "invisible heating" which can be personally controlled to the desired temperature, and an appeal is being made for £50,000 to cover the cost of the enlargements.

Bristol Hospital Service.

The Bristol Hospitals Committee has launched an appeal for £250,000 for modernising and extending the city's hospitals. The money, which it is hoped to raise in seven years, will be used for the following purposes, the number of additional beds being stated in parenthesis: New hospital at Winford (100); reconstruction and enlargement of the Eye Hospital (50); additions to the Royal Infirmary (30); additions to the General Hospital (14); enlargement of Winford Orthopædic Hospital (60); reconstruction and additions to the Children's Hospital, including an outpatients' department and a new nurses' home; additions to the Homœopathic Hospital and enlargement of the outpatients' department.

Motor Accidents and Hospital Treatment.

The Motor Vehicles and Road Traffic Bill, which has been read a second time in the Parliament of Northern Ireland, provides that, when an insured person injured in a road accident is treated in hospital, the authorised insurer or owner will be liable for the cost of treatment up to £25.

Ashton-under-Lyne Hospital.

The governors of the Ashton-under-Lyne District Infirmary have decided, owing to the large debt, that the Summers wing—nearly half the accommodation—will have to close. The infirmary has a debt of £16,000, and they have only about £2000 to meet current liabilities of £3000.

West Ham Children's Hospital.

Mrs. Parsons, chairman of the hospitals committee of the West Ham town council, recently opened a new municipal children's hospital at Harold Wood. The buildings, which have cost £41,000, consist of four blocks, each containing two wards, with two single-bed wards for special cases. Altogether there is fresh accommodation for 116 patients.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Nov. 18th.—5.30 P.M., GENERAL MEETING OF FELLOWS. 8 P.M., PATHOLOGY.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Demonstration: Mr. Duncan C. L. Fitzwilliams (introduced by Dr. E. Graham Little): Rodent Ulcer and Lupus Vulgaris. Dr. H. Corsi: Alopecia Totalis (Cured by Ultra-violet Light). Case for Diagnosis; ? Plexiform Neuroma. Dr. M. Horan (for Dr. W. J. O'Donovan): Extensive Hairy Pigmented Nævus. Dr. H. W. Barber: Nævus Unius Lateralis; Angeioma Serpiginosum. Dr. Knowsley Sibley: Lichen Nitidus. Other cases will be shown. 8 P.M., ANNUAL DINNER OF THE SOCIETY, May Fair Hotel.

FRIDAY.—5 P.M., BALNEOLOGY AND CLIMATOLOGY. Presidential Address: Dr. F. G. Thomson: The Rôle of Hydrology in Preventive Medicine. 7.30 P.M., Annual Dinner of the Section at the Welbeck Palace Hotel. 8 P.M., OBSTETRICS AND GYNÆCOLOGY. Specimens: Mr. John H. Hannan: 1. Large Bilateral Krukenberg's Tumours of the Ovary. 2. Endothelioma of the Ovary. 3. A Peri-urethral Fibroma. 4. Dermoid Cyst of the Ovary with a Basal Celled Carcinoma in its Wall. 5. Carcinoma of the Body of the Uterus from a Young Woman. 6. Carcinoma of the Fallopian Tube (slide). 7. Primary Carcinoma of the Urethra (slide). Discussion on the Interim Report of the Departmental Committee on Maternal Mortality and Morbidity. Openers: Dr. T. Watts Eden and Dr. J. S. Fairbairn. 8.30 P.M., ELECTRO-THERAPEUTICS. (Cases at 7.30 P.M.) Dr. Justina Wilson: 1, 2, and 3. Tuberculosis Cutis. 4. Arthritis of the Shoulder Joint with Brachialgia. Treated by Diathermy. Dr. E. P. Cumberbatch: 5. Old-standing Lupus Vulgaris. Dr. C. A. Robinson: 6. Cervicitis Treatment by Diathermy. Sir Robert Stanton Woods: 7, 8, and 9. Subacute Dermatomyositis. Dr. L. D. Bailey: 10. Mal-union or Radius Treated by Diathermy. Dr. E. J. Deck: 11 and 12. Intra-pelvic Protusion of Acetabulæ.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

WEDNESDAY, Nov. 19th.—5 P.M., Prof. William Rothenstein: Painting and the Healing Art (Lloyd Roberts Lecture).

HUNTERIAN SOCIETY.

MONDAY, Nov. 17th.—9 P.M. (at The Cutlers' Hall, Warwick-lane, London), Discussion on The Place of the Doctor in Industry, when the following have promised to take part: Sir David Milne-Watson, Mr. W. A. Appleton, Prof. E. L. Collis, and Dr. Strickland Goodall.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, Nov. 20th.—8.15 P.M. (at the Hospital for Tropical Diseases, Endsleigh-gardens, Gordon-street, W.C.), Demonstrations by Sir Aldo Castellani, Sir Thomas Carey Evans and Dr. G. R. Mather Cordiner, Dr. N. Hamilton Fairley, Dr. E. P. Hicks, Col. S. P. James, Dr. G. Carmichael Low, Mr. John F. Marshall, Drs. P. Manson-Bahr, W. Salisbury Sharpe, H. S. Stannus, Prof. Warrington Yorke, Dr. D. Uvedale Owen, and others. During the evening a short cinema film illustrating beri-beri will be shown; and the Manson lecture theatre, the new laboratories, operating theatre, X ray department and wards will be open for inspection.

ROYAL INSTITUTION, 21, Albemarle-street, W.
THURSDAY, Nov. 20th.—5.15 P.M., Mr. L. C. Martin, D.Sc.: Colour Vision (1).

LONDON CLINICAL SOCIETY.
TUESDAY, Nov. 18th.—8 30 P.M. (at the London Temperance Hospital), Annual General Meeting and Clinical Evening.

ROYAL MICROSCOPICAL SOCIETY, B.M.A. House, Tavistock-square, London, W.C.
WEDNESDAY, Nov. 19th.—5 P.M., Mr. R. J. Bracey, F.Inst.P.: A Universal Tube Length and Cover-glass Correcting Lens System for Use with Microscope Object-Glasses. Dr. W. E. Cooke and Mr. C. F. Hill, M.Inst.M.M.: Microscopical Studies in Pernicious Anæmia. I.—The Hæmoglobiniferous Cells.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Nov. 17th.—5 P.M., Mr. C. P. G. Wakeley: Demonstration of Specimens Illustrating the Pathological Conditions of the Spine and Spinal Cord.
FRIDAY.—5 P.M., Sir Arthur Keith: Specimens Illustrating Enlargement of the Prostate, with an Account of Our Knowledge of the Ætiology of the Condition.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Nov. 17th to SATURDAY, Nov. 22nd.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, Special M.R.C.P. Lectures at 8.30 P.M., as follows: Tues., Dr. T. Izod Bennett: The Conception of Nephrosis. Fri., Dr. W. J. Adie: Diseases of the Nervous System (1). Mon., at 4 P.M., Free lecture by Mr. L. C. Rivett: Recent Advances in Gynæcology and Obstetrics.—GOLDEN-SQUARE THROAT HOSPITAL, W., Mon., Out-patient Demonstration at 2 P.M. by Mr. F. C. Ormerod. No fee for attendance.—KING'S COLLEGE HOSPITAL, Denmark-hill, S.E. Wed., Neurological demonstration in Out-patient Department at 2 P.M., by Dr. M. Critchley. No fee for attendance.—ROYAL NORTHERN HOSPITAL, Holloway-road, N. Wed. at 6 P.M., Demonstration on Gonorrhœa in the Female by Dr. Violet Russell.—Women graduates only admitted. No fee for attendance.—CITY OF LONDON HOSPITAL, Victoria Park, E. Special post-graduate course in diseases of the Heart and Lungs. All day.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Second week of special course in medicine, surgery, and gynæcology. WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Special post-graduate course in Neurology. Daily at 5 P.M.—LONDON LOCK HOSPITAL, Dean-street, W. Third week of post-graduate course in Venereal disease.—Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Nov. 17th.—10 A.M. to 1 P.M., Surgical Wards, Genito-Urinary Operations, Skin Department. 2 P.M., Operations, Surgical Wards, Medical, Surgical, Eye and Gynæcological Out-patients.
TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clinical Demonstration (Surgical), Dental Department. 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.
WEDNESDAY.—10 A.M. to 1 P.M., Medical and Surgical Wards, Children's Medical Out-patients. 2 P.M., Gynæcological and General Operations, Medical, Surgical, and Eye Out-patients.
THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Demonstration of Fractures. 2 P.M., Operations, Medical, Surgical, and Genito-Urinary Out-patients.
FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Department, Dental Department, Clinical Demonstration (Medical). 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.
SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacterial Therapy Department, Medical Wards, Children's Medical and Surgical Out-patients.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Nov. 17th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

KING'S COLLEGE, Strand, W.C.
THURSDAY, Nov. 20th.—5 P.M., Mr. W. Robson, D.Sc.: Protein Metabolism (Second of four lectures.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark hill, S.E.
THURSDAY, Nov. 20th.—9 P.M., Dr. J. L. Livingstone Functional Disorders of the Colon.

UNIVERSITY COLLEGE, Gower-street, W.C.
MONDAY, Nov. 17th.—5 P.M., Mr. L. E. Bayliss, Ph.D.: Respiratory Functions of the Blood. (Second of four lectures.)

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Nov. 17th.—12 noon, Dr. Greenfield: Deficiency Diseases. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Alcoholism.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: Craniocerebral Topography.
WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Myasthenia Gravis.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M. Dr. James Collier: Acute Diseases of the Spinal Cord and Brain Stem.

BRITISH INSTITUTE OF RADIOLOGY, INCORPORATED WITH THE RONTGEN SOCIETY, 32, Welbeck-street, London, W.
THURSDAY, Nov. 20th.—8.30 P.M., Mr. G. Simon: Diathermy in Pneumonia. The place of Diathermy as a therapeutic agent in pneumonia. Detailed description of technique used and reasons for the adoption of this technique. Dr. A. Müller, Ph.D.: An X Ray Generator with a Rotating Water-Cooled Target.
FRIDAY.—2 P.M.–4 P.M., Visit to the Radiological Department of Charing Cross Hospital.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 18th.—5 P.M., Dr. H. W. Barber: Bacteriology and Mycology.
THURSDAY.—5 P.M., Dr. I. Muende: Pathology Demonstration.

CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C.
THURSDAY, Nov. 20th.—5 P.M., Dr. J. A. Willett: Importance of Antenatal Care.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.
WEDNESDAY, Nov. 19th.—4 P.M., Dr. Donald Hunter: Calcium and Phosphorus Metabolism.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Nov. 19th.—4.30 P.M., Mr. Kenneth Walker: Prostatitis and Prostatic Calculi.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Nov. 21st.—4 P.M., Mr. Nicol Rankin: Acute Affections of the Pharynx.

ROYAL NORTHERN HOSPITAL, Holloway-road, W.
TUESDAY, Nov. 18th.—3.15 P.M., Dr. Bruce Williamson: Demonstration of Ward Cases.

THE CHADWICK TRUST.
FRIDAY, Nov. 21st.—7.30 P.M. (at The Town Hall, Gateshead), Dr. Matthew Ray: Treatment of Rheumatism.

INSTITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, Nov. 19th.—3.30 P.M., Dr. Doris Odlum: The Importance of a Healthy Mind.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 19th.—4 P.M., Dr. A. Massey: Prevention of Venereal Disease.
THURSDAY.—4 P.M., Dr. Maude E. Kerslake: Contraceptiv Problems of Destitute or Injured Women.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.
FRIDAY, Nov. 21st.—3.30 P.M. (at the Royal Infirmary), Dr. Barnes: Syphilis of Cardiovascular System.

ST. JOHN'S HOSPITAL, Morden Hill, Lewisham.
MONDAY, Nov. 17th.—4.30 P.M., Dr. John Gibbens: Habitual Vomiting in Infants.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 18th.—4.15 P.M., Mr. D. L. Sewell: Radium and Cancer of the Larynx.
FRIDAY.—4.15 P.M., Dr. D. Stewart: The Function of the Dental Tissues.

ANCOATS HOSPITAL, Manchester.
THURSDAY, Nov. 20th.—11 A.M., Dr. W. J. S. Reid: Clinical Demonstration. 4.15 P.M., Mr. P. G. McEvedy: Minor Surgery

Appointments

BLACKER, C. P., M.B., M.R.C.P. Lond., has been appointed General Secretary of the Eugenics Society.

BOYD, J., M.B., B.Ch. R.U.I., D.P.H., Senior Medical Officer under Medical Benefits Act for Northern Ireland.

GODDARD, C. E., M.D. Durh., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for Wembley.

KENT, M., M.B., Ch.B. Manch., Assistant School Medical Officer for Derby.

PENROSE, L. S., M.D. Camb., Research Medical Officer, jointly appointed by the Medical Research Council, the Darwin Trust, and the Royal Institution, Colchester.

WARNER, N. S. HEEGAARD, L.D.S. R.C.S. Eng., Honorary Dental Surgeon to the British Dental Hospital, London.

Certifying Surgeons under the Factory and Workshops Acts: IRVING, G., M.D., B.S. Durh. (Stockton-on-Tees), and LAFFERTY, G. P., M.B., B.Ch. N.U.I. (Castleton, Derby).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Mental Hospital.—Jun. Asst. P. £300.

Bethnal Green Hospital, Cambridge-road, E.—Asst. M.O. £350.

Birmingham City Maternity and Child Welfare Committee.—Asst. M.O. £500.

Birmingham General Hospital.—Surg. Cas. O. £400.

Bolton Infirmary and Dispensary.—Two H.S.'s. Each £150. Also Cas. O. At rate of £150.

British Guiana.—Asst. Government M.O.H. £650.

British Hospital for Functional Mental and Nervous Disorders, 72, Camden-road, N.W.—Hon. Physician.

Chester County Mental Hospital.—Jun. Asst. M.O. £350.

City of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.

Connaught Hospital, Orford-road, E.—Res. H.S. At rate of £100. Also Hon. Visiting Dental Surgeon.

Elizabeth Garrett Anderson Hospital, Euston-road.—H.P., Obstet. Asst., and Three H.S.'s. Each at rate of £50.

Hackney Hospital, High-street, Homerton, E.—Deputy Med. Supt. £550.

Hendon, Colindale Hospital.—Jun. Asst. M.O. £500.

Hospital for Consumption and Diseases of Chest, Brompton, S.W.—Asst. in Dept. of Pathology. £350.

Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150. Also H.S. and H.P. Each at rate of £100.

Hull Royal Infirmary.—Asst. H.P. At rate of £130.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.

L.C.C.—Jun. Asst. M.O. for Mental Hospital Service. £500. Also 8th Asst. M.O. £445.

Leeds, St. James's Hospital.—H.P. and S. £200.

Leicester Royal Infirmary.—Surgical Dresser. 10s. 6d. per week.

Leyton, Borough of.—Asst. M.O. £500.

Liverpool, Royal Children's Hospital, Myrtle-street.—Res. Cas. O. £250.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. Also H.P. At rate of £120 and £100 respectively.

Liphook, Hants, King George's Sanatorium for Sailors.—Asst. M.O. At rate of £200.

Liverpool and District Hospital for Diseases of the Heart.—H.P. At rate of £100.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.

Manchester, Ancoats Hospital.—Part-time Med. Reg. and Surg. Reg. Also H.S. All at rate of £100.

Manchester City, Abergele Sanatorium.—Med. Supt. £900.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—Med. Reg. £150. Also Res. Clin. Pathologist. £100.

Metropolitan Hospital, Kingsland-road, E.—Asst. M.O. to X Ray and Electrical Dept.

Middlesbrough Education Committee.—Asst. School M.O. £500.

National Hospital, Queen-square.—H.P. £150.

Newcastle General Hospital.—Sen. Res. M.O. £300. Also H.P. and H.S. Each at rate of £100.

Newcastle-upon-Tyne Hospital for Sick Children.—Res. H.P. At rate of £100. Res. Sen. H.S. Also Jun. H.S. Each at rate of £100.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst. S. to Eye Department.

New Zealand, Hawkes Bay Hospital, Napier.—Pathologist. £750.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Plymouth, South Devon and East Cornwall Hospital.—H.P. Also H.S. to Casualty and Special Dept. At rate of £120 and £100 respectively.

Preston, Biddulph Grange Orthopædic Hospital.—Sen. H.S. At rate of £250.

Prince of Wales's General Hospital, N.—Hon. Clin. Assts. to Various Departments.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, N. Kensington.—Hon. Asst. Anæsthetist and Hon. Assist. Dental Surgeon. Also H.S. At rate of £100.

Queen's Hospital for Children, Hackney-road, E.—H.P. At rate of £100.

Royal College of Surgeons of England.—Election to Court of Examiners.

Royal Free Hospital, Gray's Inn-road, W.C.—Surg. Reg. £200. Res. H.S. to Ear, Nose, and Throat Dept., Res. Cas. O. £150. Res. Anæsthetist to Gynæcological, &c., Unit. £150. Half-time Gynæcological Reg., Med. Reg., and District Obstetric Asst. Each £100. Also Res. H.S.'s, H.P.'s, Asst. Anæsthetist, &c.

Royal National Orthopædic Hospital, Great Portland-street, W.—Hon. Asst. Surg.

Royal Northern Hospital, Holloway, N.—H.S. At rate of £70. Also Two Surgeons.

Ryde, Royal Isle of Wight County Hospital.—Res. H.S. At rate of £180.

St. George's Hospital, S.E.—Sen. and Two Anæsthetists.

St. Giles Hospital, Brunswick-square, S.E.—Two Asst. M.O.'s £350.

Sheffield Royal Hospital.—Ophth. H.S. Also Res. Anæsthetist. Each at rate of £80.

Sidcup, Kent, Queen Mary's Hospital for Convalescent.—Jun. Asst. M.O. £250.

South-Western Fever Hospital, Landor-road, Stockwell, S.W.—Jun. Asst. M.O. £500.

Sunderland, Durham County and Sunderland Eye Infirmary.—H.S. £350.

Todmorden Borough.—M.O.H. and School M.O. £800.

Warwick, Hertford Hill, King Edward VII. Memorial Sanatorium.—Jun. Asst. M.O. At rate of £200.

West Bromwich and District General Hospital.—Hon. Anæsthetist. Also Hon. Asst. Ear, Nose, and Throat Dept.

West Bromwich, Hallam Hospital.—Res. H.P. £250.

West London Hospital, Hammersmith-road, W.—Hon. Reg. to Throat, Nose, and Ear Department.

Wigan, Royal Infirmary.—H.S. At rate of £150.

Willesden General Hospital, N.W.—Hon. Clin. Asst. to Surgical Out-patient Dept.

Willesden Urban District Council.—Public Vaccinator.

Willesden U.D.C., Health Department.—Dentist. £420.

Yelverton, Udal Torre Sanatorium.—Res. M.O. £450.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Silverton (Devonshire), Chichester (Sussex), Dunmow (Essex), Rayleigh (Essex), and New Tredegar (Monmouthshire).

Births, Marriages, and Deaths

BIRTHS.

BARLAS.—On Nov. 2nd, at Crescent-road, Ipswich, the wife of Major A. R. Barlas, R.A.M.C., of a son.

HAWLEY.—On Nov. 2nd, at "Hazelbeech," Eaton-road, Coventry, the wife of Arthur Thomas Hawley, M.A. Camb., F.R.C.S.E., of a son.

SANSOME.—On November 8th, at Sandwell House, West Bromwich, the wife of T. Heywood Sansome, M.B., Ch.B., of a daughter.

SMITH.—On Nov. 6th, at Haddon Lodge, Shooters Hill, S.E., the wife of C. Moore Smith, of a son.

MARRIAGES.

HARDY—MOORE.—On Nov. 7th, at Brighton, George Wilfrid Hardy, M.R.C.S. Eng., L.R.C.P. Lond., of Shoreham, to Dora, third daughter of Mr. and Mrs. Stanley Moore, of Clarendon-terrace, Brighton.

DEATHS.

DAVIES.—On Nov. 5th, after a short illness, at Templecrone, Westcombe Park-road, Blackheath, Hugh Davies, F.R.C.S. Eng., M.B., B.S., of Harley-street, and Llanerfyl, Montgomeryshire.

DAWES.—On Nov. 4th, at Glenthorne, Putney Park-avenue, S.W., Herbert Edwin Tonge Dawes, M.R.C.S., L.R.C.P., aged 49.

GRAHAM.—On Nov. 3rd, at Paignton, Simon Dickson Graham, M.B., C.M. Edin., late R.A.M.C.

HARRIS.—On Nov. 5th, very suddenly, at Queen's-road, S.E., Dr. Edwin Gabriel Harris, M.R.C.S., L.R.C.P. Lond., in his 39th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

HOW TO INDEX.

AN indexer is in this respect like a butler—that the better he does his work the less he is noticed. Dr. Walsh made an index to a book of his own a few years ago and was piqued by his reviewer, who remarked "the book is furnished with a moderately good index," to have another try, when he was rewarded with getting the mark "excellent." The reviewer added parenthetically: "Excellence in indexes is not too common." Dr. Walsh, who is principal assistant in the National Physical Laboratory, has now set out the principles of indexing in a little book of 112 pages[1] which can be read with interest and appreciation by all who have suffered from slovenly and unimaginative indexing. His rules are simple and lucid, and if the writers of medical books can induce their indexers to take them to heart, their readers will be spared much heartburning. The modest price of the book places it within the reach of every indexer. Anyone who thinks that indexing is a task for babes might be asked to say what are the catchwords for the phrase "Method of grinding concave mirrors for reflecting telescopes." Dr. Walsh discards "method" as not sufficiently distinctive to be useful, and suggests himself that the phrase might be indexed under either of two nouns, a gerund, an adjective, or a participle.

EVANS'S LIST.

Messrs. Evans Sons, Lescher, and Webb, Ltd. (Liverpool and London), have brought out their annual price list in an up-to-date form. It is divided into three sections, distinguishable by the colour of the paper, the first containing pharmaceutical and biological products with a therapeutic index, the second, ampoules, capsules, pills, and tablets, and the third surgical instruments and medical sundries. In the prices current of pharmaceutical products care has been taken to mark, with a distinctive sign, articles which are covered by the Dangerous Drugs Regulations, as well as those which come within Part I. and Part II., respectively, of the Poisons Schedule. This is a very convenient arrangement. The list will be sent to any medical practitioner or student who applies to Evans's Biological Institute, Higher Runcorn, Cheshire.

UKUSIZA ABA LIMELE.

THE first-aid movement on the Witwatersrand Gold Mines has made rapid and vigorous growth and its extension to the training of natives in methods of first-aid has been one of its most useful manifestations. The more intelligent native labourers are interested in the subject for its own sake, and this interest is further encouraged by a system of bonuses and badges for those labourers, boss boys and others, who take their first-aid certificates. Inter-mine competitions are arranged and a shield is competed for annually. The excitement among the native spectators at these contests can be intense and their comments are amusing, being caustic or appreciative as the performance of a team seems to them to warrant. The late Dr. H. T. H. Butt, who was, until his recent death, a most valued and active member of the Mine Medical Officers' Association, produced a little book[2] which should be of great service to the natives and their instructors for whom it was prepared. This public being largely illiterate, the letterpress, in the Zulu, Xosa, and Sesuto languages, is reduced to a minimum, but the illustrations are so ample and clear that explanatory notes are unnecessary. It is a compilation that would be useful for a more advanced public than that for which it was intended.

SMALL-POX AND THE PUBLIC.

To the Editor of THE LANCET.

SIR,—The letter to a school-teacher from the father of an absent scholar, quoted by Dr. C. Berkeley Way in your issue for Nov. 8th, is so delightfully humorous that we ought to be grateful to Dr. Way for publishing it.

As regards Dr. Way's serious point that the public are now realising the trivial character of variola minor, and talking about "only small-pox," is it not about time that the Ministry of Health, in the interests of preventive medicine, officially sanctioned some alternative name to "small-pox" for this non-fatal, non-disfiguring, inoffensive and trifling affection, and reserved the name "small-pox" for the very serious and fatal disease which really deserves that name?

Some day the public contempt for "small-pox" which has resulted from issuing the same name for two very different things may have disastrous consequences.

I am, Sir, yours faithfully,

C. KILLICK MILLARD.

Health Offices, Leicester, Nov. 11th, 1930.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

W. J. M. Sadler to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. P. B. Moroney to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: D. J. MacDougall, C. A. Slaughter, A. J. Bado, R. R. Evans, D. C. Bowie, G. W. Rose, and G. D. Gripper.

The undermentioned Majs. are restd. to the estabt.: J. W. Hyatt and T. H. Twigg.

Lt. W. F. Cooper to be Capt.

TERRITORIAL ARMY.

Capt. R. V. Powell (late R.A.M.C.) to be Capt.

Lt. H. M. Coope resigns his commn.

ROYAL AIR FORCE.

M. J. Cahalane is granted a temporary commission as a Flight Lt.

Dental Branch: F. F. Kennedy is granted a non-permanent commission as a Flying Officer.

INDIAN MEDICAL SERVICE.

Capt. (prov.) B. N. Hajra is confirmed in rank.

The undermentioned appts. are made: To be Capt. (prov.) (on prob.): Capt. Raghubansa Kishore Tandon, from I.M.S. (T.C.). To be Lts. (on prob.): Lt. Bhagwan Das Khurana, from I.M.S. (T.C.); Lt. Diwan Chand Chopra, from I.M.S. (T.C.); Lt. Jaswant Singh, from I.M.S. (T.C.); Lt. Debi Prasad Mitra, from I.M.S. (T.C.); and Jeremiah O'Neill.

COLONIAL MEDICAL SERVICES.

The following appointments have been made: Dr. B. A. Moss, Dr. L. D. Pringle, and Dr. C. E. Vardy, Medical Officers, Federated Malay States; Dr. J. A. R. Selby, Health Officer, Hong-Kong; Dr. J. Horne, Lady Medical Officer, Nigeria; Dr. M. L. Cowan, Lady Medical Officer, Straits Settlements; Dr. H. G. Calwell and Dr. G. A. Wilson, Medical Officers, Tanganyika Territory; and Dr. A. H. Mowat, Medical Officer, Uganda.

West African Medical Staff: Dr. L. W. Banks and Dr. W. E. S. Merrett, Medical Officers.

NEW BATH HOSPITAL.—On Oct. 28th the Mayor of Bath laid the foundation-stone of the new Royal United Hospital at Coombe Park, Bath, which will cost £100,000. The first portion to be built will provide 100 beds, administrative and service blocks.

ADDRESSES AND ORIGINAL ARTICLES

INDICATIONS FOR TREATMENT IN PULMONARY TUBERCULOSIS.

The Mitchell Lecture delivered before the Royal College of Physicians of London on Nov. 13th

BY L. S. T. BURRELL, M.D. CAMB.,

FELLOW OF THE COLLEGE; PHYSICIAN TO THE ROYAL FREE HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

IT is usually a simple matter to decide whether a patient has been infected with tuberculosis, but it is often extremely difficult to determine whether or not the lesion is active. Yet on this depends the need for treatment.

The problem commonly comes before the practical physician in one of two ways. In the first he is asked for an opinion as to whether a certain series of symptoms, such as lassitude, wasting, cough, in a patient previously healthy, is due to active tuberculosis. In the second he is asked whether a patient who admittedly has had pulmonary tuberculosis still has active disease requiring further treatment or whether it has become arrested.

Before discussing these questions it seems to me wise to consider briefly the current views on infectivity and immunity. On this subject there is a wide difference of opinion, and consequently there are different views not only as to the nature of treatment but also as to what type of patient requires any treatment at all, either for prevention or cure.

Infection and Immunity.

Tuberculin may be of little value but it has at least brought out the fact that a large proportion of human beings is infected with tuberculosis. Yet only a few develop clinical tuberculosis. Since so many are infected and so few affected it follows that the majority of people keep well without any treatment at all. To submit anyone to a long course of unnecessary treatment is not only useless but may do untold harm. Many a healthy person has been frightened into invalidism by the threat of tuberculosis. Instead of following a normal career, the patient gives up business and devotes his life to health. He develops fads about food and clothing, cannot live in this or that climate, must winter out of England, is in a constant state of anxiety about his health, and is never really happy. Bad as this is for an adult, it may be much worse for a child if taken away from school and companions of a like age at the most impressionable time of life. On the other hand, an active tuberculous lesion is very amenable to treatment in the early stages, but if neglected quickly gets out of control. It is, therefore, of the utmost importance to distinguish between the tuberculous and those who are out of sorts through some other cause. These latter require treatment, but it is usually a matter of adjusting the mode of life, or in the case of children of arranging diet. Doubtful cases should be watched at frequent intervals, but only after the fullest consideration should a patient be diagnosed as tuberculous and sent away for a long course of treatment. It must be remembered that if tuberculosis is lurking in the body, a prolonged sea voyage or holiday will not necessarily prevent the development of clinical pulmonary disease, and in many cases the patient would be better carrying on his usual occupation under medical supervision. Work is healthy, holidays sometimes are not.

Now in the prevention or treatment of early disease much depends on the view taken of immunity conferred by infection. If we believe that a small infection or series of infections protects the individual effectively, then the correct procedure is to treat those who fail to react to tuberculin either by exposing them to infection or inoculating them with tuberculin or an emulsion of attenuated tubercle bacilli. Some have actually protested against the pasteurisation of milk on the grounds that by repeated small infections through the milk the child gradually acquires immunity. The opposite view is that clinical disease cannot occur without infection, and the essence of prevention should be to abolish or dilute as far as possible all sources of infection, so that there may be as little chance as possible for infection or reinfection.

According to the first view it is those who fail to react to tuberculin who are in danger; they are the unvaccinated. According to the second view the reactors are not effectively protected and are in danger from activation of their own lesions as well as of a chance reinfection. These views should be carefully examined, since they vitally affect the policy of the campaign against tuberculosis, as well as our opinion of the indications for treatment in an individual case.

RESISTANCE OF THE INFECTED.

Now, if one takes a broad view, tuberculosis of the infant is quite different in type from that of the adult in most civilised communities. Amongst certain primitive races, or those who have not been brought into contact with tuberculosis, the adult does not acquire resistance, and if infected develops the infantile type of the disease—that is, an acute generalised tuberculosis which proves fatal in a few months or even weeks. A race may be completely free from tuberculosis until the white man comes and introduces it; then follows an acute form which may decimate the population. In their native state monkeys are free from tuberculosis, but in captivity it is a common cause of death. One diseased monkey will infect others in the same cage and the type of disease is that found in infants, acute and rapidly fatal. Experimentally it is known that if living tubercle bacilli are injected into an animal which has not previously been infected there is no immediate reaction and it remains quite well for a time, but later, if the dose is sufficient, it becomes ill and dies of generalised tuberculosis. If tubercle bacilli are injected into an animal which has previously been infected there is an immediate reaction which may be fatal. If it survives, however, recovery may take place without any actual disease developing provided the infecting dose was not too great. If disease does occur it progresses much more slowly and is associated with attempts at healing, as indicated by the formation of fibrous tissue. Infection of a non-immune animal, therefore, produces an acute type of tuberculosis such as occurs in infants and people who have not previously been exposed to the disease. Infection of an immune animal produces an entirely different type of disease which is chronic and, although usually fatal in the end, is associated with serious attempts at healing which are at times successful. This is the type of disease commonly seen in adults in civilised countries.

It will be seen that there is definite experimental

and clinical evidence to suggest that resistance develops from infection. Resistance, in the sense that the addict is resistant to morphia, does undoubtedly occur; but I suggest that this is different from resistance or immunity such as is produced by vaccination against small-pox.

It is true that the usual type of disease in the infant is acute and generalised, but in the great majority of cases the child resists the infection and fixes the disease, not in the lungs with resulting chronic fibroid disease, but in the glands. Unless miliary tuberculosis develops the disease seems to pass through the lungs of the infant without producing any lesion. Children are particularly free from pulmonary tuberculosis until they reach the age of puberty. Then the mortality rises. The rise occurs earlier in girls than in boys and in girls of 16 to 20 years of age the mortality from pulmonary tuberculosis is greater than that from tuberculosis from all causes in the infant. To explain this rapid rise in mortality by assuming that the specific resistance to tuberculosis is lowered by the strain of life that occurs about puberty seems to me to be very unconvincing. No such failure of resistance to other conditions such as measles occurs at that time. Moreover, if one makes a series of tuberculin tests one finds that a positive reaction occurs with increasing frequency from infancy to adult life. There is no falling-off in the number of reactors to tuberculin as puberty and the great increase in the incidence of tuberculosis occur. In the primitive races the incidence and type of the disease does not appear to be in any way dependent on whether they have been tuberculinised or not as shown by the reaction to tuberculin. Different races are affected differently, as in the case of animals; the sheep, for example, is immune but the cow is susceptible. Although half a century has passed since Koch discovered the tubercle bacillus, no recognised method of protection against tuberculosis has been evolved either by tuberculin or emulsion of living bacilli. The reported success of experiments with B C G still awaits confirmation. Griffiths failed to protect monkeys by B C G, and the abolition of tuberculosis as a serious menace to monkeys in captivity in many zoological gardens followed better ventilation, housing conditions, and light—and not the tuberculinisation of the animals.

If infection really protects, it is difficult to see why patients with a mild tuberculous lesion, such as pleural effusion or a small pulmonary lesion which has apparently healed, should be more liable to get a recrudescence of active disease than others. They are not only not protected against clinical tuberculosis but are rendered more liable to get it. Evolution by the survival of the fittest produces wonderful protective powers in the animal body, and a race which has to live in a country where tuberculosis or typhoid or yellow fever is endemic tends to become much more resistant to it than a race where the disease does not occur. The body also develops defensive powers against any poison gradually introduced and one would expect the chronic consumptive to have considerable resistance—as in fact he has. If he has no resistance he dies rapidly before he has time to become a chronic consumptive. True immunity such as occurs after small-pox, scarlet fever, &c., is surely an entirely different thing from the resistance which develops from habit in such cases as alcohol, arsenic, or I venture to suggest, tuberculosis. It is not a question of relative immunity; the two are completely different. In one case the individual having had small-pox is immune and can live in an atmosphere of small-pox. In the other the effect of the poison is modified as the body becomes accustomed to it, but there is no real protection, and death from tuberculosis eventually occurs in the majority of cases.

INFECTION SHOULD BE PREVENTED.

For these reasons I am of opinion that failure to react to tuberculin is not an indication for treatment. An attempt to protect by tuberculin or tubercle bacilli seems to me to be wrong. Clinical tuberculosis develops from a tuberculous lesion. If there is no lesion it cannot develop. The policy that appeals to me is therefore to prevent infection, and if this is impossible, to dilute it as far as possible. In practice it is found that where this has been done by sanitation, cleanliness, and correcting overcrowding, there tuberculosis has decreased. There is no evidence that any success has followed attempts to diminish the incidence of the disease by producing immunity. There is evidence that in certain cases where attenuated tubercle bacilli have been injected to produce immunity clinical and fatal tuberculosis supervened.

The Suspected Early Case.

If the patient reacts to tuberculin it may be assumed that he has been infected. The problem then is to decide whether the symptoms are the result of a tuberculous lesion or whether the lesion is not active and the symptoms are due to some other cause. In the first case, treatment should be directed against the tuberculosis; in the latter the tuberculous lesion, as indicated by the tuberculin test, is accidental and requires no treatment. I shall now consider a number of symptoms which are associated with tuberculosis of the lungs.

SYMPTOMS.

Cough is so commonly present that its absence must be taken as evidence against the diagnosis of pulmonary tuberculosis. In some cases of acute miliary tuberculosis, however, there is no cough. Paroxysmal morning cough accompanied with vomiting is not uncommon in the later but not in the early stages of the disease. It is more frequent in alcoholics with bronchitis. People who smoke too many cigarettes usually have some cough. Cough which suddenly develops and lasts more than a month is suggestive, and of 611 patients admitted to Brompton Hospital with pulmonary tuberculosis it was the first symptom noticed in 44·8 per cent.

Sputum is often absent in the early stages and when it appears it is mostly mucus, and tubercle bacilli are not found. A negative sputum test in the early stage is of little value, but when once the sputum has become purulent failure to find tubercle bacilli is very strong evidence indeed against the disease being active tuberculosis. Kingston Fowler reports 188 cases from Midhurst Sanatorium and in these tubercle bacilli were found in the sputum on the first examination in 167 and on the second in 12 cases. That is to say, that in only 9 out of 188 cases were they not found at the first or second examination.

Fever.—In early active disease there is usually some rise of temperature in the evening. The typical tuberculous temperature is an exaggeration of the normal curve, highest in the evening and lowest in the morning. If the temperature is taken at 6 P.M. and 8 A.M. it will bring out the highest and lowest reading. In tuberculosis, however, it is increased by exercise, so that when investigating a case the temperature should be taken immediately after exercise and subsequently at intervals of 15 minutes in order to note the time it takes to fall. A slight evening rise of temperature alone is not enough for a positive diagnosis to be made. It is common in children with

digestive trouble, in toxæmia from other causes, and in women before menstruation.

Night sweats are common in the early stages of the disease, but usually disappear when the patient is put to bed and does not have too many bed-clothes. They are not common in hospital cases. Patients who wake up at night feeling hot will often complain of night sweats, but this is not important. True night sweats as a result of which the night clothes have to be changed are very suggestive of tuberculosis in an acute stage. In a chronic case they indicate an acute exacerbation and are of serious omen.

Debility.—Loss of energy is present in the great majority of cases and it was the first symptom noticed in 9·5 per cent. of 611 cases at Brompton Hospital. It is almost invariably associated with some localising symptom such as cough.

Loss of weight.—In the very early stages loss of weight is often slight. It was the first symptom in only 2·3 per cent. of the 611 Brompton Hospital cases. Persistent loss of weight for no apparent cause is far more likely to be due to some other condition.

Loss of voice is an occasional early symptom and should arouse suspicion if associated with other symptoms. Persistent loss of voice should always lead to a thorough investigation of the chest, including examination with X rays. If tuberculous laryngitis is found it should be assumed that the lungs are also infected.

Dyspnœa.—Shortness of breath is not common in the early stages, except in tuberculous broncho-pneumonia, when it is extreme.

Dyspepsia.—Digestive troubles are occasionally the first symptoms noticed by the patient, but they are usually associated with some more obvious complaint, such as cough.

Hæmoptysis may occur as a result of mitral stenosis, bronchiectasis, fibroma of bronchus, malignant disease, or other causes, and a thorough examination should be made. If, however, no other cause can be found it should always be taken to indicate tuberculosis of the lungs. Large veins may be seen at the back of the throat, but they never cause hæmoptysis. It does not follow that hæmoptysis in tuberculosis is necessarily an indication for treatment of the tuberculosis. It is common in chronic fibroid cases and often no treatment is required except during the actual hæmorrhage. In the great majority of cases, however, especially those who were previously supposed to be healthy, hæmoptysis does indicate active disease requiring treatment.

Pleurisy.—Idiopathic pleurisy is almost invariably tuberculous. It occurs in many local conditions, such as neoplasm, bronchiectasis, or abscess of lung, and it is always present in pneumonia. In chronic wasting diseases there is often pleurisy, and pleural effusion is common in cases of renal disease or heart failure. If, however, it occurs in the apparently healthy as a result of a chill, or sitting in a draught, or for no obvious reason, it should be regarded as of tuberculous origin. If an effusion forms and clear fluid containing an excess of lymphocytes is found a definite diagnosis should be made. It should be borne in mind that pleural effusion develops as a result of tuberculosis of the lungs. We know, therefore, that the lungs are already affected. With treatment, or in some cases without treatment, the pulmonary lesion may heal, but in some 40 per cent. of the cases it goes on to a definite form of clinical pulmonary tuberculosis which can be detected by physical signs and symptoms.

PHYSICAL SIGNS.

In some schools nowadays it is the custom to belittle the value of physical signs. Let us try to estimate their value fairly. In the first place it must be admitted that one often sees a patient who has been examined by several experienced physicians, but in whom no physical signs are found, yet in whose lungs there is tuberculosis as indicated by the presence of tubercle bacilli in the sputum, the evidence of X rays, and the subsequent development of physical signs. It is evident, therefore, that it is quite unjustifiable to say that a patient has not got tuberculosis of the lungs because he has been examined by one or even several physicians with special experience of chest work, and no physical signs have been detected. Again, physical signs are often misleading. A little dullness at one apex may be due to scoliosis, old pleurisy, or muscular development; it cannot reasonably be taken as an indication of early tuberculous disease of the lung. By the time any impairment of the percussion note is obtained, the disease has progressed far beyond the stage in which it should have been detected by symptoms or radiographic examination. It does happen sometimes, though very rarely, that on examination of an apparently healthy person definite signs are found. In this case there is usually good resistance and fibrosis is taking place. None the less, because it does occasionally reveal the presence of unsuspected disease, physical examination of so-called contacts is important. The point I wish to emphasise is that if no physical signs are found, it is no evidence whatever that the patient is free from tuberculosis. On the other hand, physical signs are important, not only because they are very occasionally the first indication of disease but because they frequently enable one to judge the spread of it. Of all physical signs the only one that is really important is the presence of moist sounds over the upper part of the lung; if these sounds are constant and increase with cough they are almost pathognomonic of tuberculosis. Other signs, such as slight flattening at one apex, impairment of percussion note, altered vocal fremitus, are not only useless in the majority of cases, but they may be actually misleading and dangerous. One is often presented with a case of hæmoptysis and sputum containing tubercle bacilli in which one finds slight impairment of note at the left apex, with diminution of movement and weakened breath sounds; and yet X rays shows the left apex to be clear, whereas there is a definite lesion at the right root and the subsequent course of the disease brings out physical signs at the right root whilst the left apex remains perfectly free. I say, therefore, examine your patient carefully but put not your faith in physical signs.

EXAMINATION WITH X RAYS.

The correct interpretation of radiographic findings is a matter of great difficulty, and it is always wise to have the collaboration of an experienced radiologist. Fine mottling of the lung, especially if seen below and just external to the midline of the clavicle, is strong evidence in favour of tuberculosis. If there is doubt a series of X ray examinations at intervals of three months should be made, and any increase in the shadows will confirm the suspicion and enable one to make a diagnosis. Shadows round the root of the lung, even if dense and exaggerated, should not lead one to a diagnosis of tuberculosis. The hilum of the lung is made up of blood and lymph vessels, bronchial tubes, and glands, and often a dense X ray shadow is seen in a patient who is found post mortem to be free of any disease in that region. Tuberculosis

starts in the lung and spreads from there; it does not start in the glands at the root and spread into the lung.

SPECIAL TESTS.

There are many special tests but none is of value except in a negative sense. I have already referred to the tuberculin test, and I shall say no more except that a negative test is evidence that the patient is not infected with tuberculosis, except under certain conditions. If the patient is moribund or seriously ill with tuberculosis the test may be negative. In two adults with typhoid fever I found the tuberculin test negative, and other illnesses have the same effect, but in a doubtful case of tuberculosis a negative tuberculin test is an indication that the patient is free from that disease. The test, however, is of little practical value, because in a civilised country the great majority of people give a positive reaction, whether or not they have or will subsequently develop clinical tuberculosis.

The opsonic index and complement-fixation tests have been tried extensively but have been found wanting and consequently have been discarded by most workers. The sedimentation test is of little value for diagnosis, although very useful as a help to the progress of the disease and to assist in treatment. For example, after the induction of an artificial pneumothorax, if the toxæmia is relieved, the sedimentation rate will fall and one is helped in judging the result of treatment by this test. A quick sedimentation rate occurs in other diseases besides tuberculosis, and in an early case of tuberculosis before toxæmia has developed the sedimentation rate may be normal.

The same applies to vital capacity, except that a normal vital capacity is very rare in pulmonary tuberculosis even in the early stages. It is useful for following the progress of the disease and for assisting in treatment, but it is lowered by many other diseases besides tuberculosis, and is of little value in diagnosis.

INDICATIONS FOR TREATMENT.

In the absence of definite evidence that the symptoms are due to tuberculosis, the patient should be kept under observation and not treated as a consumptive. If there is definite evidence, thorough treatment should be started at once. The slighter the amount of disease the more urgent is the need for treatment, because the patient then has a chance, and with proper care, a very good chance of complete recovery. There is a world of difference between being well and being patched up. A patient will often say he is not bad enough to go into a sanatorium, but the physician should remember that this is a fallacy and that the main function of a sanatorium is to restore to complete health those who have not yet passed into the incurable stage of the disease.

It is therefore of the utmost importance to decide whether a patient is suffering from tuberculosis which is progressing and in need of treatment, or whether the symptoms are due to some other cause, and tuberculosis, if present, is already healed. To sum up my remarks about physical signs and symptoms:—

1. Hæmoptysis of unknown origin should be taken to indicate pulmonary tuberculosis.
2. Pleural effusion is the result and not the cause of pulmonary tuberculosis, unless it is due to some other definite condition such as neoplasm or heart failure. After recovery from the effusion the patient should always be treated as an early and active case of tuberculosis of lung.
3. X rays are by far the most important method of examination and a definite diagnosis can often be made by this means alone. It is however essential to interpret the radiographic findings correctly and to avoid the many errors, the most common of which is to mistake heavy root shadows for disease of the lung.
4. Physical signs are misleading, but the presence of constant moist sounds over the upper part of the chest may for all practical purposes be taken as definite evidence of tuberculosis.
5. The presence of tubercle bacilli in the sputum is conclusive.

Of the signs and symptoms no one is sufficient for a diagnosis to be made, but in combination they may lead to a suspicion so strong that a positive diagnosis is justified. For example, a patient develops a cough which persists for a few months, he also feels easily tired and slack, and is found to have a slight rise of evening temperature, and this rise is exaggerated by exercise. Even if the X rays show what appears to be normal lungs and there are no physical signs such a patient should be put to bed and treated as a case of early but active tuberculosis.

The Chronic Case.

So far I have reviewed the indications for treatment in patients who are probably infected with tuberculosis but who have never had the disease as it is known clinically. I shall now consider the indications for treatment in the chronic fibroid type of case.

In all active cases when there is fever or signs of spreading disease the need for treatment is obvious. When fibrosis has occurred the patient wants to return to his usual occupation and recreations and wishes to know what treatment, if any, is required to prevent a relapse. It should be remembered that there is always need for treatment in the sense that the patient should lead a quiet, regular life, avoiding excess of all kinds. Strain and excess tend to shorten the life of anyone, but in the case of the consumptive there is the additional danger that they will cause a relapse of the disability. Sedentary work in an office is better than a strenuous life in the open air. Fresh air is good for everyone, including the consumptive, and it is especially desirable in his case because if he gets below par he is more liable to a serious breakdown that is the ordinary man. Unnecessary exposure to cold may do harm, especially to the elderly. Let us say therefore that for the fibroid-arrested case there is always need for treatment, but the only treatment required is for the patient to lead a wise, restful life. Apart from this, treatment is required only if the disease again becomes active. The indications of reactivity are the appearance of certain symptoms and physical signs.

Loss of weight.—During sanatorium life patients are apt to put on too much fat and they usually lose some of this when they return to their occupation. This is not important, but a steady loss of weight below the normal is an indication for treatment.

Loss of energy.—If the patient feels overtired after his day's work, and especially if the tiredness increases, treatment is necessary.

Evening rise of temperature suggests that there is some active disease, but other causes of pyrexia should be investigated.

Return of cough and sputum indicate the necessity for treatment, at least until they have disappeared again.

Hæmoptysis should be treated, but it does occur repeatedly in some chronic cases without doing any apparent harm and they can continue at work between the attacks.

Pleurisy is not infrequent, but here again the patient is often well after the attacks and does not require prolonged treatment.

The patient should be examined periodically, and an increase in the physical signs, and especially an

increase in the lesion as seen by X rays, shows that the disease is spreading and treatment is required. Finally, it should be remembered that an idle life is not a healthy one and that many a patient will live longer if he thinks less of his own health and settles down to some suitable occupation.

THE INTERRELATION OF NEUROSYPHILIS AND CARDIOVASCULAR SYPHILIS

BASED ON THE STUDY OF FIFTY CASES.

BY FRANCIS BACH, M.D. OXF.,

MEDICAL OFFICER TO OUT-PATIENTS, NATIONAL HEART HOSPITAL; CLINICAL ASSISTANT, WEST END HOSPITAL FOR NERVOUS DISEASES;

AND

C. WORSTER-DROUGHT, M.D. CAMB., M.R.C.P. LOND.,

PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES AND TO THE METROPOLITAN HOSPITAL.

THE association of neurosyphilis with syphilis of the cardiovascular system from time to time has attracted the attention of a number of observers. Most of the literature of the subject has emanated from German sources and a perusal of these records indicates that evidence of syphilis of the cardiovascular system has been found clinically in over 30 per cent. of cases of neurosyphilis, while post-mortem signs have been obtained in over 50 per cent. Also, there is evidence to suggest that the clinical diagnosis of neurosyphilis is usually made in the fourth decade of life, whereas cardiovascular syphilis in the majority of cases is recognised only in the fifth decade. In several years' experience of the malarial treatment of early general paralysis it has occurred that some cases, showing no definite clinical evidence of cardiovascular disease, have died suddenly during the pyrexial course. At autopsy in these cases, aortitis and myocardial disease has invariably been found. The experience of Lowenberg,[1] of Hamburg, has been similar; he reported, in 1924, that since the introduction of malarial therapy 20 of his cases had died during the course of treatment, and in the majority an aortitis had been found at autopsy. Gerstmann[2] and Rudolf[3] also mention several such deaths during or following malarial therapy. As it is essential to appreciate the condition of the cardiovascular system in cases of neurosyphilis before undertaking the risk of malarial therapy, and in view of the foregoing observations, it occurred to us to ascertain: (1) if it were possible in cases of neurosyphilis to detect cardiovascular syphilis, by the application of special cardiological methods, at an earlier stage than that at which the more definite physical signs appeared; (2) if evidence could be obtained as to the early signs of syphilitic aortitis; and (3) if cardiovascular syphilis, as revealed by such clinical methods, was more frequent in neurosyphilis than was generally supposed.

Our investigation, therefore, has been essentially clinical and has been approached both from the neurological and the cardiological aspects. Thus, in 25 cases of neurosyphilis attending the West End Hospital for Nervous Diseases solely on account of their neurological symptoms, we have made a complete examination of the cardiovascular system by clinical, orthodiagraphic, and electrocardiographic methods. We have compared this group of cases with a further series of 25 cases of cardiovascular syphilis referred to the National Heart Hospital purely for their cardiac condition. In these cases we have carried out similar investigations, together with a detailed clinical examination of the nervous system.

The details of the two series of cases are given in the Tables.

TABLE I.

Twenty-five Cases of Neurosyphilis.

Tabes and taboparesis	..	20	..	Male	17	..	Female 4
General paralysis	..	5	..	„	4	..	„ 0
					21		4

Average age, 43 years.

Average interval since primary infection in 14 known cases, 21·5 years.

Main Symptoms.

Tabes and taboparesis.			General paralysis.	
Unsteady gait	.. ..	12	Nervousness and loss of power concentration	.. 4
Precipitant and difficult micturition	.. ..	4	Failure of memory	.. 1
Failing vision	.. ..	2		
Gastric crises	.. ..	1		
"Lightning" pains	..	1		
		20		5

Symptoms referable to cardiovascular system, nil.

Cardiovascular syphilis: Definite evidence; suggestive evidence, 1 case each.

The Wassermann reaction was positive in the cerebro-spinal fluid or blood, or in both, in all the cases.

TABLE II.

Twenty-five Cases of Cardiovascular Syphilis.

Syphilitic aortitis with aortic incompetence	.. ..	23	..	Male	17	..	Female 6
Syphilitic aneurysm	..	2	..	„	1	..	„ 1
					18		7

Average age, 47 years.

Average interval since primary infection in known cases, 20 years.

Main Symptoms.

Shortness of breath on exertion, 15

Retrosternal pain on exertion, 10

Symptoms referable to central nervous system, nil.

Neurosyphilis: Definite evidence in four cases; typical tabes dorsalis; pupillary changes only, two each.

The Wassermann reaction was positive in the blood in the 25 cases.

Description of Cases.

(*a*) *Neurosyphilitic series.*—Of the 25 cases of neurosyphilis investigated, seven showed some degree of variation from the normal in the cardiovascular system. Of these seven, one patient exhibited definite evidence of cardiovascular syphilis—viz., a woman with tabes dorsalis, aged 38 years. Clinically there was no cardiac enlargement; the aortic second sound was distinct; and basal diastolic murmurs, retrosternal and conducted to the apex, were present in the aortic area. Blood pressure 130/90. X ray examination showed slight enlargement of the heart to the left and fullness to the right in the first part of the aorta. Electrocardiograph: Low voltage curve with subphysiological T wave in all leads.

One case showed evidence suggestive of syphilitic cardiovascular disease—a woman, aged 35, with taboparesis. Clinically, there was slight cardiac enlargement and accentuated aortic second sound. Blood pressure 135/90. X ray: Slight enlargement of the heart to left, horizontal type; aorta shows slight fullness to the right, especially in the first part. Electrocardiograph: Subphysiological type of curve. A further case, a man aged 42 with tabes

dorsalis, showed transposition of viscera with clinical, X ray, and electrocardiographic pictures characteristic of dextrocardia. Two cases, both men, aged 47 and 49 respectively, showed evidence of hypertension with slight cardiac enlargement and, on X ray examination, fullness of the aortic shadow. Two further men with tabes dorsalis, aged 53 and 56 respectively, showed evidence of arterio-sclerosis and atheroma of the aorta with probable previous hypertension.

(*b*) *Cardiovascular series.*—Of the 25 cases of cardiovascular syphilis examined, four showed clinical evidence of neurosyphilis. All four had typical Argyll-Robertson pupils, and two of these, in addition, showed classical signs of tabes dorsalis—absent knee- and ankle-jerks, impairment of deep sensation, and some degree of incoördination. In all four cases the neurosyphilis was associated with syphilitic aortitis and aortic incompetence.

SPECIAL INVESTIGATIONS.

(1) *Clinical.*—Of the early clinical signs of syphilitic aortitis, a basal aortic systolic murmur and an accentuated aortic second sound are considered to be the most characteristic. In the 25 neurosyphilitic cases no basal systolic murmur was heard. An accentuated aortic second sound was appreciated in two cases only, one being the case described as probable early syphilitic cardiovascular disease and the other suffering from hypertension.

In the cardiovascular group, 23 cases showed a definite basal to-and-fro systolic-diastolic murmur, and in two cases of anuerysm, a basal systolic murmur and a ringing aortic second sound were present.

(2) *Radiographic examination.*—The characteristic signs of syphilitic aortitis are: Evidence of slight cardiac enlargement to the left, increase of the aortic shadow to the right in its first part, especially if the heart is not enlarged; and evidence of uniform dilatation of the aortic shadow or of aneurysm. Of the 25 cases of neurosyphilis, in one there was evidence of increase of the aortic shadow to the right and absence of cardiac enlargement—the case diagnosed as syphilitic aortitis. One case showed fullness of the aorta in its first part, associated with slight cardiac enlargement—the case suggesting early syphilitic aortitis. In three of four cases with hypertension there was slight cardiac enlargement and diffuse fullness of the aortic shadow. One case showed dextrocardia.

In the radiographic examination of the cardiovascular series, there was evidence of cardiac enlargement in all, and of definite fullness of the first part of the aorta to the right in 20 of the 25 cases.

(3) *Electrocardiograph.*—Observations were made on evidence of auricular fibrillation, on the P–R interval for prolongation of the auriculo-ventricular conduction time, widening and notching of the Q R S complex—suggesting some degree of intraventricular block, on variation in the S–T interval, and in the shape and relative size of the T wave in any or all of the three leads.

In the series of neurosyphilitic cases, there was no evidence of definite alteration in the electrocardiograph records. In eight cases the waves were definitely subphysiological in type, with flattening of the T wave in all leads. In the present state of our knowledge the exact significance of this is obscure. In the case of dextrocardia, there was a characteristic inversion of P–Q and T in lead I. In the cardiovascular series of cases, electrocardiographic abnormalities were frequent. Prolongation of P–R occurred in none, prolongation of Q R S in five cases, in three of which there was definite notching with evidence of right branch bundle block. Definite left-sided preponderance was present in ten cases, T_1 physiological in five, flat in 17, and definitely inverted in 3 (all of whom complained of retrosternal pain). T_2, T_3 inversion occurred in one case.

Early Diagnosis of Cardiovascular Syphilis.

Neurosyphilis usually manifests itself at an earlier age than syphilitic aortitis. There is, indeed, evidence to suggest that in the majority of cases the clinical diagnosis of neurosyphilis is made in the fourth decade of life, whereas cardiovascular syphilis is usually recognised only in the fifth decade. This observation was emphasised by Kessler,[4] in 1924, in a pathological study of 59 cases of tabes dorsalis, of which 39 exhibited signs of cardiovascular syphilis. Those cases under 40 years of age, however, showed no evidence of luetic changes in the aorta. Bauer [5] has reported the case of a woman aged 42, under treatment for tabes, who after two years presented definite clinical signs of aortitis. This contention is also borne out by our own series of cases, the average age of the neurosyphilitic group being 43 years, while that of the cardiovascular syphilitic group was 47. Further, Stokes [6] has pointed out how rarely cardiovascular syphilis is recognised in the first decade following infection, and that in his own series of cases 45 per cent. were diagnosed in the second decade after the initial infection with syphilis. Consequently, we felt that by a complete cardiological examination of neurosyphilitic cases, some evidence might be obtained as to the early signs of syphilitic aortitis.

Subjective symptoms cannot be relied upon to suggest an examination for the presence of cardiovascular syphilis. In cases of neurosyphilis with aortitis, our experience has been that the patients seldom complain of any symptoms referable to the cardiovascular system. Also in Frisch's series,[7] of nine cases showing clinical evidence of cardiovascular syphilis, only two complained of such symptoms—retrosternal pressure. It may also be noted that those cases of our cardiovascular series exhibiting signs of neurosyphilis had no symptoms referable to their neurological condition.

On clinical examination of cases of neurosyphilis, an accentuated aortic second sound, especially if accompanied by borderline enlargement of the heart to the left, may be taken as suspicious of early aortitis. The suspicion becomes a probability if radiographic examination confirms even slight cardiac enlargement and shows fullness of the aortic shadow to the right in its first part. The latter condition was present in two of our cases of neurosyphilis, and on this finding alone we should hesitate to advise malarial therapy. The development of a basal systolic murmur is further evidence, and if, in addition, a soft basal diastolic bruit appears, the diagnosis of syphilitic aortitis is conclusive.

In cases of syphilitic cardiovascular disease that have been studied with the electrocardiograph, one of the most important alterations in the curve has been that of the T wave. Willius,[8] in 99 cases of cardiovascular syphilis, found an abnormal T wave in 23, an abnormal Q R S in 22, significant T wave negativity in 17, and arborisation block in 9 cases. Pardee and Juster [9] found that of 50 cases with syphilitic aortitis, of which about two-thirds had aortitic incompetence, the electrocardiograph showed an abnormal T wave in 85 per cent. of the cases;

inversion of T_1 occurred in 26 per cent.; in 20 per cent. it was of the "coronary" type; and in 38 per cent. of those cases without evidence of valvular lesion T_1 was abnormal. Significant abnormalities in the Q R S complex were found in 40 per cent. of the cases. In the series, ten autopsies were obtained, and from a study of the pathological material and the electrocardiographic records, it appeared that the abnormality of the T wave was probably due to encroachment upon the lumen of the coronary orifices by the syphilitic disease in the sinuses of Valsalva. Pardee and Juster conclude that the greater frequency of the T wave changes in patients with aortic incompetence is due to the fact that in these patients the aortitis involves the region of the valves near which the coronary arteries originate.

The only electrocardiographic change we have to record in the series of 25 neurosyphilitic cases examined is flattening of the T wave in all leads, and in the present state of our knowledge the exact significance of this is obscure. Alterations in T_1 were noted in 20 of the series of 25 cases of cardiovascular syphilis.

Association of Neurosyphilis with Cardiovascular Syphilis.

(1) *Pathological evidence.*—In 1923, F. Frisch [7] published a series of 115 cases of neurosyphilis from Wagner-Jauregg's clinic in Vienna in which 45 cases (39·1 per cent.) showed pathological evidence of syphilitic aortitis. Kressler,[4] in 1924, reported the results of a pathological study of 59 cases of tabes dorsalis of which 39 (66·1 per cent.) showed signs of syphilitic mesaortitis. In the same year (1924) Lowenberg,[1] of Hamburg, found that in 341 cases of general paralysis, 33 per cent. showed evidence of aortitis at autopsy. From these figures it would appear that, whether clinical evidence be present or not, an average of over 45 per cent. of cases of neurosyphilis also suffer from cardiovascular syphilis.

(2) *Clinical evidence.*—In 1907, Rogge and Müller [10] of Breslau, recorded a series of 22 consecutive cases of tabes dorsalis of which eight (36·3 per cent.) showed definite clinical evidence of syphilitic cardiovascular disease. In six of these eight cases aortic incompetence was present. The average age of the patients was 43·5 years. Denke,[11] in 1913, reported 153 cases of syphilitic aortitis, of which 63 (41·1 per cent.) showed physical signs of neurosyphilis; of these 63 cases, 12 showed definite signs of tabes, and 17 characteristic pupillary changes. In Frisch's series [7] of 115 cases, nine only (7·5 per cent.) showed clinical evidence of syphilitic aortitis or aneurysm—in contrast to the 39·1 per cent. showing pathological changes in the aorta at autopsy. Forty-five of the 115 patients were suffering from tabes dorsalis, and of these six (13·3 per cent.) showed clinical evidence of syphilitic aortitis. It is interesting to note that of the whole series, two alone complained of subjective symptoms—retrosternal pressure—referable to the cardiovascular system. From these figures, it is concluded that an average of 20 per cent. of neurosyphilitics are expected to show clinical evidence of cardiovascular syphilis.

(3) *Commentary.*—A consideration of our own series of cases suggests the conclusion that in this country at the present time clinical manifestations of cardiovascular syphilis are less frequent in cases of neurosyphilis than the above figures—nearly all from German sources—would indicate. In spite of the application of special methods, only 4 per cent. of our cases of neurosyphilis showed definite evidence, and an additional 4 per cent. suggestive evidence of syphilitic aortitis, even at an average age when syphilitic cardiovascular disease is frequently recognisable. Of the cases of cardiovascular syphilis, 16 per cent. showed signs of neurosyphilis; this also is in marked contrast to Denke's figure of 41 per cent.

Our acknowledgements are due to Dr. Strickland Goodall for kindly allowing us to investigate cases under his care at the National Heart Hospital.

Summary and Conclusions.

1. A series of 25 of the younger cases of neurosyphilis, attending a hospital for diseases of the nervous system on account of neurological symptoms, were fully investigated from both the cardiovascular and neurological aspects.

2. In a series of 25 cases of cardiovascular syphilis of a comparable age, attending a hospital for diseases of the heart on account of cardiac symptoms, similar observations were made on the nervous and cardiovascular systems.

3. Of the 25 cases of neurosyphilis, one case only showed definite clinical evidence of syphilitic aortitis, and in another case there existed signs suggesting this condition. Four cases showed signs of arteriosclerosis and hypertension.

4. Of 25 cases of cardiovascular syphilis, four showed evidence of neurosyphilis. Of these, two were suffering from tabes dorsalis and two showed characteristic pupillary changes.

5. Radiographic examination revealed the presence of increase in the aortic shadow characteristic of syphilitic aortitis in only two cases in the neurosyphilitic group, while in the series of cases of cardiovascular syphilis all 25 yielded this positive result.

6. With the electrocardiograph, low-voltage curves were found in eight of the cases of neurosyphilis, but no definite abnormalities. Of the 25 cases of cardiovascular syphilis, 20 showed abnormalities; in particular, prolongation of the intraventricular conduction time was noted in five cases, and alteration of T_1 in 20 cases.

7. Even with modern instrumental methods of diagnosis, relatively few cases of neurosyphilis (8 per cent.) showed clinical evidence of cardiovascular syphilis. Similarly, however, relatively few cases of cardiovascular syphilis (16 per cent.) revealed signs of neurosyphilis. This is in contrast to figures from German clinics.

8. Early signs suggesting a diagnosis of syphilitic aortitis are: (1) Accentuation of the aortic second sound; (2) on X ray examination, enlargement to the left and slight fullness, especially to the right, of the first part of the aorta; and (3) in the electrocardiogram, abnormalities such as widening of the Q R S complex and flattening or inversion of the T wave, especially in the first lead.

APPENDICITIS IN THE SCHOOLBOY.*

By L. E. Barrington-Ward, Ch.M., F.R.C.S. Edin., F.R.C.S. Eng.,

SENIOR SURGEON, ROYAL NORTHERN HOSPITAL; SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

It has long been recognised that it is advantageous to consider diseases at different age-periods. It is for this reason that children's hospitals have been formed all over the world. Certain diseases only occur between the ages of 1 and 12, and between these limits the reaction of the organism to infections and injuries differs from other age-groups. Similarly adolescence, 12 to 21, has its own peculiarities of behaviour, perhaps less sharply marked from childhood but differing considerably from adult life. In boys of school age certain differences present themselves. Acidosis, manifested as it is in childhood in such varied and frequent forms, hardly ever occurs. This is some comfort to us, because attention has been so strongly directed on acidosis, that it is uncommon to find any case of recurrent appendicitis in the child to which the diagnosis has not at some time or other been applied. After the age of 12 this bugbear is a rapidly decreasing one.

The age of adolescence has other compensations. Diseases of the stomach, duodenum, and gall-bladder are so rare that they may be almost disregarded. Malignant disease and the degenerative diseases, such as diverticulitis and visceroptosis, are hardly to be considered. We are left with a few diagnostic stumbling blocks—rare peritoneal infections, referred conditions of the lung and genito-urinary tract, congenital malformations of the intestines, errors of rotation and persistence of embryonic structures—which may show themselves first at any age.

There is only one more difference which has struck me in considering acute abdominal diseases at different ages and that, perhaps, is a psychological one. Boys of school age are on the whole rather secretive as regards their complaints. An attack of appendicitis may occur and may proceed to gangrene and even perforation before a formal complaint is made. I have seen this delay on several occasions and I am unable to decide whether the inflammation is more acute, whether the discomfort is less acute, or whether a misplaced desire for freedom determines this self-imposed heroism. Possibly school traditions play their part in encouraging or discouraging the confessional of the sick room.

One would expect in a modern school, organised from the health point of view, with sick room, nursing staff, and a regular system of reporting, it would be an easy matter to attain the ideal and secure every case of appendicitis with the inflammation limited to the appendix. My experience is that this is by no means always the case. Possibly stoic endurance is sometimes the cause, but it may be that a more fulminating type of case is found in years of adolescence than in any other period.

Acute Appendicitis.

DIAGNOSIS.

In about 90 per cent. of cases the first symptoms are obstructive. The appendix is blocked by a fæcolith, the products of inflammation, or a kink, and writhes spasmodically to empty its contents. At this initial stage the features are central abdominal pain, colicky in nature, accompanied in some cases by vomiting. Sudden obstruction of any hollow viscus, be it small intestine, Meckel's diverticulum, renal pelvis, or ureter, may give rise to very similar features. The only distinguishing sign at this stage may be a slight tenderness on pressure over the right iliac fossa. So long as the infection is confined to the lumen of the appendix no true rigidity of the abdominal muscles is noted. With the extension of the infection to the peritoneal covering of the appendix, tenderness at McBurney's point and localised involuntary rigidity of the muscles covering the right iliac fossa begin to show themselves. This extension of the infection inhibits appendix movements and the central colicky pain ceases. In its place begins persistent pain in the right iliac fossa. If the process continues the infection spreads to the parietal peritoneum and involuntary rigidity gives a guide to its extent. The area involved and the intensity of this rigidity depend on the anatomical position of the appendix. If the appendix is near the anterior abdominal wall, tenderness and rigidity are early manifest and reach the highest degree of development. If the appendix lies in the pelvis, the rigidity is lower in situation and later in development, although the maximum point of tenderness may still be over McBurney's point. If the appendix is retrocæcal, the tenderness and rigidity show themselves in the loin. The pelvic peritoneum is surprisingly tolerant to infection and unproductive of painful stimuli. This explains why a pelvic appendix comes to operation later than any other variety.

Vomiting may or may not occur. The initial pains may be accompanied by vomiting, but it is rarely a pronounced feature, and it nearly always follows the pain and does not precede it. Excessive vomiting always makes one look for some condition other than appendicitis. The temperature is usually raised soon after the beginning of the attack, but it may remain normal throughout, and it rarely reaches a high level. A temperature over 103° would certainly make one consider another diagnosis. The pulse is always raised and is the best indication of the severity of the attack. The pulse-rate varies a good deal in health, and a knowledge of the boy's normal pulse is of great assistance. The bowels are usually mildly constipated, but in the case of a pelvic appendix, an irritable diarrhœa is sometimes an early sign. I have often thought that the description of a typical attack of appendicitis sounds so simple that errors in diagnosis can hardly ever arise. I am aware that variations of symptoms and signs do arise even in straightforward cases, but I believe they are all capable of an explanation if a constant effort is made to correlate the clinical features with the probable pathological conditions present. The real difficulties are met with when the anatomical position is abnormal with a high undescended cæcum, or a left-sided cæcum, or where the inflammation is complicated with some other lesion such as obstruction. I have recently operated on a case where the small intestine had become snared by passing under a Meckel's diverticulum adherent to an inflamed appendix which had perforated, and naturally the signs were most confusing.

DIFFERENTIAL DIAGNOSIS.

Acute lobar pneumonia at its onset sometimes simulates appendicitis. The inflammation beginning deep in the lung near its diaphragmatic surface may produce intense abdominal pain and right-sided rigidity. No respiratory signs at first are manifest,

* Introducing a discussion at a meeting of the Medical Officers of Schools Association on Nov. 7th.

except quickened respirations and perhaps a cough. A high appendix impinging on the diaphragm may be closely mimicked. In the differential diagnosis, stress can be laid on these points. In pneumonia the temperature as a rule is higher, the facies is rather distinctive, the tenderness and rigidity are most marked in the upper right half of the abdomen. Pressure on the left side of the abdomen does not increase the right-sided pain, as it would if peritonitis were present. Moreover, the onset is rather too abrupt for such full development of physical signs, if the appendix was to blame. In the course of a few hours physical signs appear at the right base and the abdominal signs recede. I have observed that such a case of pneumonia is often followed by a basal effusion which may become purulent.

There are some other diseases which the textbooks tell us to take note of in discussing the differential diagnosis. Pyelitis, renal calculus, pneumococcal peritonitis are examples. At the age and in the sex that we are discussing they are not common. Tuberculosis of the abdominal glands sometimes simulates appendicitis with central abdominal pain, tenderness in the right iliac fossa, and a moderate degree of pyrexia. As a rule the attack is so mild and fleeting that operation, except by the overzealous, is not considered. In nearly every case careful palpation will reveal a lump in the typical situation. The short duration and mild character of the attack exclude the possibility of the lump being an appendix abscess.

Inflammation of a Meckel's diverticulum must always be borne in mind. It may simulate appendicitis very closely. The only possible distinguishing features are the more central tenderness and rigidity and a greater degree of small intestine distension than would be expected in appendicitis. I have not found any altered appearance of the umbilicus of much assistance in diagnosis.

Primary pneumococcal peritonitis is rare in boys. Fraser and McCartney believe that the infection is always through the genital tract and only occurs in girls. This has not been my experience. Of 14 cases at Great Ormond-street, nine were in females and five in males. In London, however, it is a rare disease. Diagnosis is difficult. The onset is more insidious than in an appendix peritonitis; there is more distension, less rigidity. The temperature is higher and vomiting is more frequent. The facies is rather distinctive. In pneumococcal peritonitis the patient is often pallid, sometimes cyanosed.

TREATMENT.

The whole surgical opinion of the world is agreed upon one point. If a case of appendicitis is seen within 24 hours of the onset of the attack operation should be undertaken. In the young with whom we are dealing I believe that operation is indicated at any stage that the condition may be recognised. In the adult it may be possible or advisable to treat cases not seen until the third or fourth day on expectant lines, but that is outside our province at the moment. Appendicitis in the boy is far more likely to lead to a progressive peritonitis than a localised abscess, and the sooner the appendix is removed the better. Delay is only permissible when the case is obviously subsiding in every feature. The mortality of early operation is less than 1 per cent. It mounts with every day that elapses. This puts a high premium on early diagnosis but, as I have said before, there will always be some cases that fail to come under skilled supervision as early as they should. In family practice a homely diagnosis and a homely purgative are usually responsible for the delay; in school life perhaps a misplaced reluctance to report sick. It is impossible to overstress the importance of withholding purgatives, but happily this complication of appendicitis is not likely to arise at school.

No preliminary treatment is necessary. Gas and oxygen or open ether are the only permissible anæsthetics. If the case is typical and early, then a muscle-splitting incision in the right iliac fossa is excellent. If the case is late or if an unusual position is suspected, then more room is required and a paramedian incision with displacement outwards of the right rectus makes for safer surgery.

To drain when in doubt is still sound practice, especially in the young. If the infection has passed through the walls of the appendix, shown by a turbid effusion in the neighbourhood, or if there is oozing from the acutely inflamed appendix bed, then a drain for 24 hours can cause no possible harm and will relieve the operator of considerable anxiety. If pus is present, then adequate drainage is essential, and a tube should be placed in both the appendix area and the pelvis. Early removal of the tubes is desirable; only in the circumscribed abscess do they function for more than three days. I believe insufficient drainage is the cause of many of the possible complications—residual abscesses, subphrenic abscess, intestinal obstruction, and empyema.

In the after-treatment rest is all important. Nothing by the mouth except water, no purgatives, morphia in the necessary quantity to soothe the patient and abolish pain, and continuous administration of 10 per cent. glucose solution by the rectum to conserve the strength and diminish thirst. Within 48 hours the worst abdominal assault will be forgotten and the intestine will have recovered its normal functions. In suppurative cases early feeding and purgatives lead to intestinal paralysis, extension of the peritonitis, toxæmia, and exhaustion.

Chronic Appendicitis.

This term in the past has covered a multitude of disorders, but it is in patients of the other sex and more mature years that its abuse has been chiefly noted. The wise surgeon is very careful nowadays before he makes such a diagnosis. At the outset one may make a safe generalisation: chronic pain always limited to the right iliac fossa, with or without chronic tenderness, is hardly ever due to the appendix.

DIAGNOSIS.

Chronic disorder of the appendix shows itself, I believe, in two forms. In the first, the more important, beneficent nature gives us warning of what is in store. The patient suffers from a series of bijou attacks of appendicitis, so evanescent that they escape the opportunity of skilled examination and merely come to us as a history. In an otherwise healthy boy, complaint is made of occasional attacks of umbilical or supraumbilical pain, occurring at rather rare intervals, often brought on by exercise. There is rarely nausea or vomiting. Sometimes there is the admission that the abdomen is sore for a little while after an attack, that an upright stance is uncomfortable, or that flexion of the right thigh causes pain in the right side. If examination can be made at such a time, tenderness on palpation of the appendix area will be noted, and the diagnosis of appendicitis can be made with some confidence. In the absence of such an opportunity, it is wiser to keep the boy under careful observation, and perhaps call in the aid of the radiologist. In this type of case the boy is perfectly well between the attacks.

In the second form, the symptoms are much more indirect. An adherent or obstructed appendix interferes with the proper functioning of the digestive tract, upsets peristalsis, and a form of chronic intestinal indigestion is set up. The boy becomes slack and pasty, and suffers from epigastric flatulence, which occasionally amounts to pain. Corrective measures in the matter of diet and mastication, and regulation of the bowels have no effect. It may be necessary to examine the abdomen many times before any tenderness is found in the appendix region. Even then it is not safe to make a diagnosis of appendicitis without further investigation.

It is in these cases that I have come to rely more and more on X rays. A skiagraph of the abdomen is taken to exclude a calculus, demonstrate any calcified glands, and show the bony skeleton. A barium meal is then given and the general progress of the shadow is followed. Ileal stasis, colon stasis, abnormal position or mobility of the cæcum and ascending colon require notice. As regards the appendix, the examination is of no value if it fails to fill. If it fills, it may be in an unusual position, or it may be fixed. There may be great delay in emptying. More important still, it may be tender on palpation. Any such appearance is suggestive and taken with the clinical picture may make the diagnosis certain. If the appendix fills and discharges in normal time, if it occupies a normal position, is mobile and is not tender, then chronic appendicitis can be excluded.

TREATMENT.

This must be by operation. In the recurrent form of chronic appendicitis I never give the appendix the benefit of any doubt. An acute attack may supervene so swiftly and perhaps at so awkward a moment in the boy's life, that nature's hint must not be disregarded. Removal of the appendix in a quiet period carries practically no mortality; a neglected appendix can cause the greatest anxiety.

IRRADIATION OF THE TRACHEO-BRONCHIAL LYMPHATIC GLANDS IN THE TREATMENT OF CARCINOMA OF THE LUNG.*

BY H. P. NELSON, M.B. CAMB., F.R.C.S. ENG.,
DEMONSTRATOR IN ANATOMY AT ST. BARTHOLOMEW'S HOSPITAL.

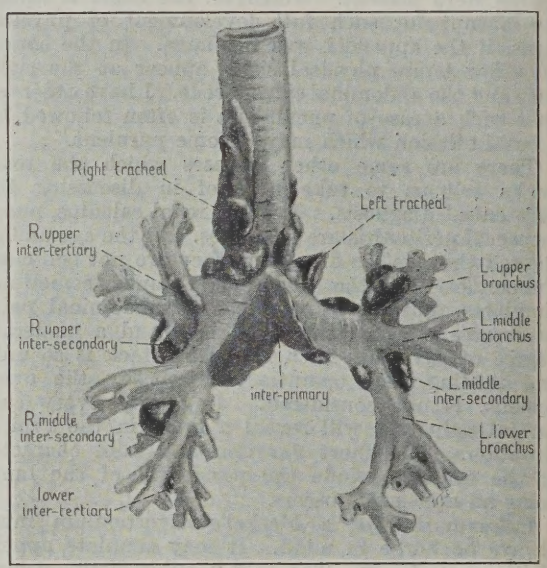
THE methods hitherto employed—lobectomy or the implantation of radon seeds from the external surface—suffer from the limitation that the lymphatic glands draining the neoplasm are left untouched. With the object of bringing the main lymphatic drainage within the scope of treatment I have undertaken some anatomical investigations on the lymphatic glands of the mediastinum and the arrangement of the bronchial tree.

Anatomy of the Bronchial Tree.

As the lymphatic glands are best described in relation to the bronchial tree it will be necessary to review briefly its anatomy (Figs. 1, 2, and 3). The trachea divides into two primary bronchi and from these extend the secondary bronchi to the lobes of the two lungs. Since the two lungs differ in their lobes, the distribution of the secondary bronchi is best appreciated by arranging them in the more symmetrical manner of four secondary bronchi on each side.

On the *right side* the primary bronchus gives off from its right lateral wall a branch to the upper lobe, the upper secondary bronchus, and then continues as the main secondary bronchus, which terminates by dividing into three secondary bronchi; a ventral

FIG. 1.



Dissection of the bronchial tree showing tracheobronchial lymphatic glands (anterior aspect).

branch to the middle lobe, the middle secondary bronchus; a dorsal branch, which leaves the main stem at approximately the same level as the middle bronchus and runs to the posterior part of the lower lobe, the dorsal secondary bronchus; and the continuation of the main stem to the rest of the lower lobe, the lower secondary bronchus.

On the *left side* the primary bronchus is twice as long as on the right. It divides into two main secondary bronchi, upper and lower, which almost immediately break up into two more; thus the four secondary bronchi on the left side all arise within a few millimetres of each other. The upper main bronchus divides into an upper secondary and a middle secondary bronchus, which are equivalent in their area of distribution to the two bronchi of the same name on the opposite side. The lower main bronchus gives off a dorsal branch to the posterior part of the lower lobe, the dorsal secondary bronchus, and then continues to the rest of the lower lobe as the lower secondary bronchus. These secondary bronchi divide into tertiary, then into quaternary, and so on.

Anatomy of the Tracheobronchial Lymphatic Glands.

These glands are fairly constant in position but vary considerably in size. They consist, broadly speaking, of three main groups:—

(*a*) Those in the *mediastinum*: (1) right and left tracheal groups; (2) interprimary groups.
(*b*) Those in the *hila of the lungs*: (3) intersecondary.
(*c*) Those in the *lung fields*: (4) intertertiary, interquaternary, &c.

(1) The *right tracheal group* occupies the right anterolateral aspect of the trachea. The broad lower

* Read before the Medical Society of London on Nov. 10th (see THE LANCET, Nov. 15th, p. 1071).

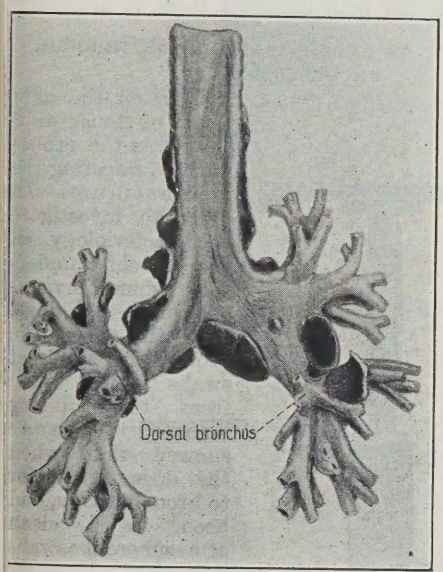
end reaches down to the level of the carina and extends from the mid-line of the trachea on to the upper surface of the right upper bronchus, but as it ascends the group gets narrower and winds backwards on to the lateral aspect of the trachea. Inferiorly is the right pulmonary artery, medially the arch of the aorta, and above this the innominate artery, while on the anterolateral aspect is the superior vena cava and further lateral is the mediastinal pleura.

The *left tracheal group* is by no means so constant as the right. The main part is situated on the lateral aspect of the trachea under the arch of the aorta. From here a chain of flattened glands extends upwards between the aorta and the side of the trachea, while another chain may extend downwards and forwards to lie in front of the left primary bronchus at its commencement and above the left pulmonary artery behind the ascending aorta. The most constant extension of this group is downwards and backwards along the lateral side of the left primary bronchus. These glands lie against the posterior surface of the pulmonary artery, and extend down to meet the left dorsal intersecondary gland.

(2) The *interprimary group* is wedged between the two primary bronchi and extends down on either side as far as the commencement of the lower lobe bronchi. The pulmonary artery is in front of this group and below in the mid-line it is separated by the oblique sinus from the left auricle and, further laterally, the upper two pulmonary veins. Posteriorly are the œsophagus and vena azygos major.

(3) The *right upper intersecondary glands* are wedged between the upper lobe bronchus and the main secondary bronchus, and they are then continued down on the lateral aspect of the main secondary bronchus behind the corresponding branch of the right pulmonary artery to meet the *dorsal intersecondary gland.*

FIG. 2.



Same dissection as Fig. 1, but showing posterior aspect.

The *right middle intersecondary glands* are in the angle between the middle and lower bronchi, in front of the artery, and to the lateral side of the lower pulmonary vein.

The *left middle intersecondary* is also between the middle and lower bronchi and in front of the artery. The *left upper intersecondary glands* are inseparable from the upper intertertiary. This happens because the upper bronchi on each side are short and divide almost immediately into ascending, anterior, and posterior tertiary bronchi.

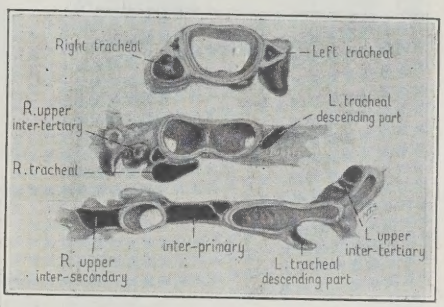
(4) Situated on the anterior surface between these are the *upper intertertiary glands.* The lower, middle, and dorsal intertertiary are further out in the lung fields and are not so constant.

Irradiation.

Since these glands lie in immediate contact with the trachea and bronchi, it occurred to me that radon seeds might be pushed from the inside, through the tracheal and bronchial walls, directly into them.

In order to test if this was anatomically possible, I tried to insert seeds in cadavers, using a special trocar and cannula operating through a bronchoscope. In the first three cases I attempted to insert the seeds into the intersecondary as well as into the interprimary and tracheal glands, but in order to implant the intersecondary an extreme degree of displacement of the trachea and bronchi was necessary—more than would have been practicable in life and especially in carcinoma where the peribronchial or peritracheal infiltration sometimes considerably limits mobility. Moreover, the smallness of these intersecondary glands and their close adhesion to the pulmonary artery make implantation in any case extremely difficult.

FIG. 3.



Three transverse sections of Fig. 1. The upper two are looking downwards and the lowest looking upwards.

I therefore confined my attention to the tracheal and interprimary glands. Starting from the carina the medial wall of the right primary bronchus was inspected and in the alternate spaces between the cartilaginous rings seeds were introduced at points 2 mm. anterior to the junction of the cartilaginous with the membranous portions of the bronchus. The same procedure was adopted in the left primary bronchus. The right tracheal glands were seeded from below upwards, the first seed being introduced just to the right of the mid-line in the first interspace above the carina, and then in alternate spaces until four to six had been introduced. The left tracheal glands may sometimes be very small but when this is so their space is occupied by fat. Three seeds were here introduced on the left anterior and lateral walls of the trachea in the first interspace above the carina. One seed was then introduced on the posterolateral wall of the left primary bronchus below the level of the carina and another into the lateral wall of the trachea above the others (Fig. 4).

In this way I irradiated seven cadavers in all and had only three badly misplaced seeds. Two were loose in the pericardium and one was in the lumen of the œsophagus. This was due, I think, to the introducers used. My first instrument had a tip at an angle to the shaft which was excellent for the tracheal but unsuitable for the interprimary. I now use a straight tip for the interprimary and an angulated tip for the tracheal group.

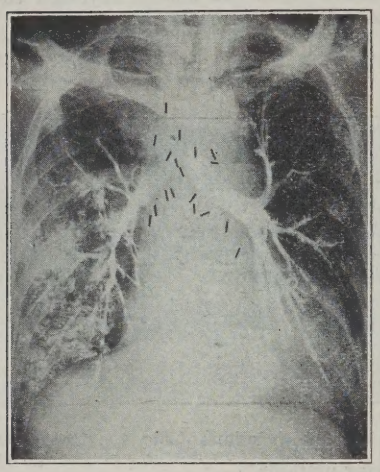
On dissection about 50 per cent. of the seeds were found buried actually in gland substance and the

other half were lying in the fatty tissue round the glands. When the viscera had been fixed in formalin and the glands made firm, the seeds are more likely to enter the glands rather than push them aside and lie in the periglandular tissue.

These experiments convinced me that only the tracheal and interprimary glands could be irradiated with accuracy through the bronchoscope. The intersecondary glands lie beyond the reach of this method and would have to be dealt with from outside through a thoracotomy. These investigations on cadavers have also led me to consider the distribution of gland metastases in carcinoma of the lung. Post-mortem records merely state "metastases in the bronchial glands" and do not mention which of these glands contained microscopic or macroscopic deposits.

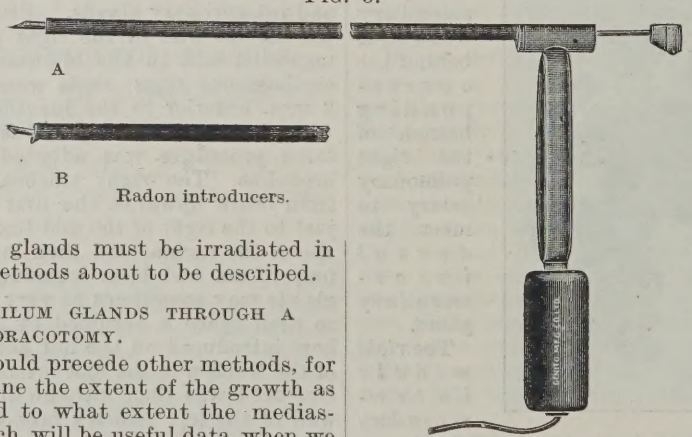
Much more knowledge is required on this problem. In the meanwhile I think that all the accessible glands must be irradiated in accordance with the methods about to be described.

FIG. 4.



Cadaveric experiment showing seeds in the interprimary and tracheal glands. The bronchial tree is injected with barium paste.

FIG. 5.



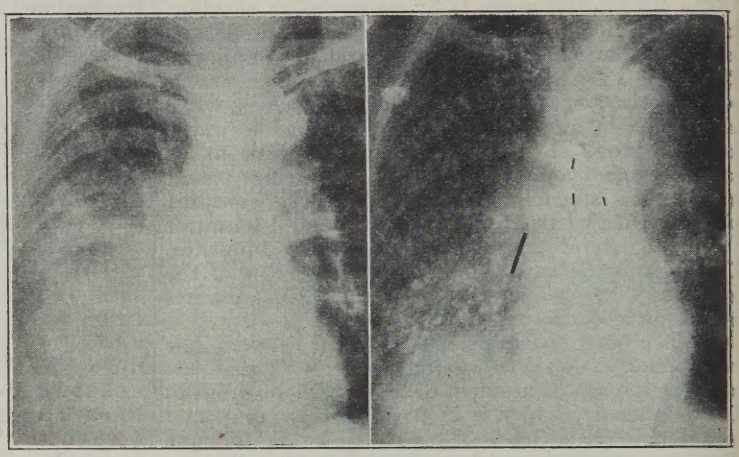
Radon introducers.

IRRADIATION OF HILUM GLANDS THROUGH A THORACOTOMY.

The thoracotomy should precede other methods, for by this we can determine the extent of the growth as against atelectasis, and to what extent the mediastinum is involved which will be useful data when we are irradiating through the bronchoscope. Where possible the lung should be collapsed, the ribs spread to give full exposure, and the exact extent of the intrapulmonary growth determined. On rare occasions lobectomy will be possible, but owing to adhesions and the invasion of the mediastinum the only treatment in the majority will be radon emanation in the form of seeds that do not require subsequent removal.

It is at this stage that the intersecondary glands will have to be irradiated. The right upper and both dorsal intersecondary glands are situated along the posterior surface of the main descending limb of the pulmonary artery while the middle intersecondary are situated just in front of this artery, which is to be found at the bottom of the oblique fissure of the lung. It is desirable (whether practicable I am not yet in a position to say) that at the thoracotomy stage this fissure be split down to the artery, the glands felt for, and irradiated. The intertertiary glands of the affected lobe will also be irradiated through the thoracotomy but in conjunction with the main mass of growth.

FIG. 6. FIG. 7.



FIGS. 6 and 7 (Case 1).—Anteroposterior radiograms of chest. Fig. 7 shows three seeds and radon needle in position.
(In these and subsequent figures the seeds have been picked out in black so as to show clearly on reproduction.)

IRRADIATION OF MEDIASTINAL GLANDS THROUGH BRONCHOSCOPE.

Having settled the anatomical question the next most obvious difficulty was the probability of infecting the mediastinum. In order to investigate the bacteriology of the bronchi I undertook some investigations on dogs. With the aid of the bronchoscope direct swabs were taken from the primary bronchi. These showed that when the dogs, just prior to bronchoscopy, had been in a clean atmosphere the swabs were sterile. Recently I have been taking swabs from cases of bronchial carcinoma. Five have been taken so far, two from patients with practically no sputum were sterile, while those from patients with sputum grew *Streptococcus salivarius* and occasionally *Micrococcus catarrhalis* but no virulent or pyogenic organisms. Further investigations on the sterility of the tracheobronchial tree are in progress, but the evidence so far is that we can assume that the bronchi are sterile in the absence of the usual signs of infection.

Technique.—In order to prevent hæmorrhage from

the punctures it was decided to employ a diathermic current to coagulate the track through the tracheal or bronchial wall. The instruments are therefore insulated with Bakalite (a boilable insulating material) except for the tip that pierces the bronchial wall. It consists of a cannula containing a blunt-pointed stilet, and when this is pushed home the tip of the stilet is flush with the sharp tip of the cannula. I use two different introducers (Fig. 5): (A) a straight tip with the bevel pointing forwards for the interprimary glands; (B) an angulated tip with the bevel pointing downwards. This is constructed to pierce the anterior tracheal wall where the angle of incidence is very small. The introducers are muzzle loaders and the seed is held in place with vaseline.

Local anæsthesia is quite sufficient. The patients are given potassium bromide grs. 30 one and a half hours before and an injection of morphia gr. ¼, hyoscine gr. 1/150, and atropine gr. 1/100 one hour before. The larynx, trachea, and bronchi are anæsthetised with local applications of cocaine.

The introducers may best be operated down a 9 mm. Jackson's bronchoscope. The seeding should proceed from below upwards in case of slight bleeding obstructing the view. The tip of the loaded introducer is pushed through the desired space between the rings, the stilet pushed home, and then a diathermic current of a few milliampères is switched on for three to five seconds according to the resistance of the patient (previously tested with raw beef). The object is to give as little coagulation as is compatible with hæmostasis.

FIG. 8.

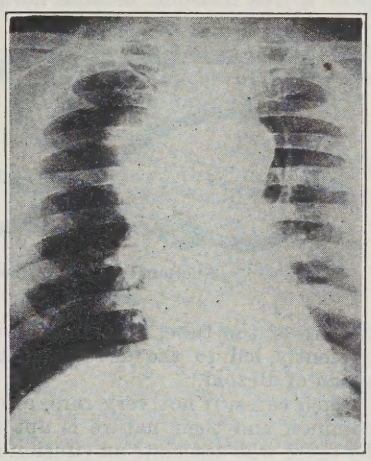


FIG. 9.

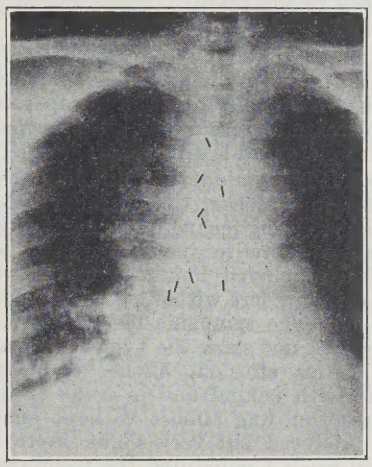

FIGS. 8 and 9 (Case 2).—Anteroposterior radiograms of chest. Fig. 9 shows nine seeds in position.

Cases Treated.

CASE I (under Dr. A. E. Gow's† care at St. Bartholomew's Hospital). A male, aged 60, by occupation a valet. Since April, 1930, he had suffered with cough, sputum, occasional hæmoptysis, and pyrexia. Sputum was examined for tubercle bacilli on many occasions but was always negative. When seen in October he had a temperature up to 101° at times, had 90 c.cm. of thick sputum a day, and was extremely emaciated and frail. The physical signs were stony dullness and absent breath sounds at the right base. Wassermann reaction was strongly positive. X ray examination showed an opacity at the right base and the aortic shadow either enlarged or displaced to the left (Fig. 6). Lipiodol failed to enter the right lower lobe.

On Oct. 9th, under local anæsthesia, I made a bronchoscopic examination and could see the right lower bronchus completely blocked with growth. A bronchial swab was taken and a piece of the growth removed with biopsy forceps for microscopy. The swab was sown on blood agar and in blood broth and these grew *Streptococcus salivarius*. The microscopic section was that of a polymorphic-celled carcinoma.

Oct. 16th. *Application of radon down the bronchoscope.* Three seeds of 0·5 mm. platinum screenage and containing 1·5 mc. were introduced, one through the medial walls of the right and left primary bronchi and another through the anterior wall of the trachea just above the carina. A radon needle containing 5 mc. with a large bead attached to one end was then pushed into the growth blocking the right lower bronchus (Fig. 7).

On Oct. 22nd the bead with the needle attached was removed. The growth blocking the lumen had shrunken to three-quarters of its size and pus was welling up from below. A tube was passed beyond the growth and as much pus as possible aspirated. The puncture holes in the tracheal and bronchial walls were looked for but could not be seen.

The patient suffered no pain; the sputum and pyrexia continued, but were no worse than before bronchoscopy, until he died on Nov. 3rd. Post-mortem examination showed a diffuse purulent effusion over the lower two-thirds of the right pleural cavity. In the upper part of the right lower lobe was a breaking-down growth 2 in. in diameter. It surrounded the bronchus and was ulcerated into it. The rest of the lower lobe showed suppurative broncho-pneumonia. Growth could only be seen in the right upper intersecondary glands, but microscopic sections of the others are in preparation. There were no signs of inflammation in the mediastinum. The tracheal and interprimary glands were not adherent to the trachea. The seed intended for the right tracheal glands was lying between the glands and the trachea, but the interprimary ones were intraglandular. No macroscopic changes could be seen round the seeds. There were no secondary deposits elsewhere in the body.

CASE 2 (under Sir Thomas Horder's care at St. Bartholomew's Hospital). A male, aged 63, by occupation a dustman. Since July, 1930, he had complained of giddiness on stooping, cough with occasional blood-stained sputum. Since August he had had pain in chest. When seen at the end of October he was a thick-set, well-nourished man, cyanosed, slight dyspnœa, and some dilated veins in the neck. He was apyrexial and had practically no sputum. There was an impaired note to the right of the sternum, but normal breath sounds in the right upper lobe. The Wassermann reaction was negative. X rays showed a shadow extending upwards and outwards from the right hilum and occupying almost the inner half of the upper and middle lung fields (Fig. 8).

On Oct. 23rd, under local anæsthesia, I made a bronchoscopic examination. The trachea was compressed and growth could be seen projecting into the lumen from the medial wall of the right primary bronchus, while the lateral wall was rigid and could not be displaced sufficiently to view the lateral surface of the bronchial wall.

Oct. 27th. *Application of radon down the bronchoscope.* Nine radon seeds of 0·5 mm. platinum screenage and containing 1·5 mc. were introduced, three through the growth occupying the medial wall of the right primary bronchus, one through the medial wall of the left primary bronchus, four through the right anterolateral wall of the trachea, and one through the left lateral wall of the trachea (Fig. 9).

After the irradiation the man ran an irregular temperature up to 101° for some days, and had sputum amounting to 50–100 c.cm. per day, but no hæmoptysis.

Nov. 5th. *Bronchoscopy.* The growth on the medial wall of the right primary bronchus was larger, occupying half the lumen; this was possibly due to œdema. The puncture holes in the trachea were occupied by small yellow sloughs, while that in the left primary bronchus looked healed. There was some pus in the right bronchus which was removed by aspiration. Since Nov. 5th the temperature and pulse have returned to normal.

These cases show quite clearly that irradiation of the tracheal and interprimary glands can be

† I wish to express my thanks to Dr. Gow and Sir Thomas Horder for their permission to publish this and the following case.

carried out through the trachea and bronchial walls without setting up a mediastinitis. This assertion is made all the more confidently because one of the cases had already a bronchial infection. The cases were too advanced to expect any amelioration of the course of the disease, and no attempt was made to irradiate with a view to curing. Nevertheless, what was done was well tolerated by the patients and showed that the method could be used in the treatment of malignant disease of the lungs.

Given now a moderately early case of bronchial carcinoma where lobectomy or a thorough irradiation is possible, it appears to me that if the tracheo bronchial glands were also irradiated the possibilit of a cure would be enhanced.

The anatomical work was carried out in the Anatom Department at St. Bartholomew's Hospital, and I woul offer my most sincere thanks to Prof. Wollard for hi valuable suggestions. I am also extremely grateful to D G. F. Stebbing, Dr. D. S. Murray, and other members of th staff of the Lambeth Hospital for offering me facilities whic made this work possible. I am also indebted to Mr. Schranz of the Genito-Urinary Manufacturing Company, who mad the instruments required for this work. A part of th expenses of this research was defrayed by a grant from th Medical Research Council.

CLINICAL AND LABORATORY NOTES

SUCTION EXPLORATORY NEEDLE FOR EXUDATION INTO THE TYMPANUM.

By Sir James Dundas-Grant, K.B.E., M.D. Edin., F.R.C.S. Eng.,

SURGEON (THROAT AND EAR), BROMPTON AND CANCER HOSPITALS; CONSULTING SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

In a case recently under my care an earlier recognition of a serous exudation into the tympanum might have led to treatment from which the patient at once received complete and lasting relief.

The patient was a lady of middle age who had been deaf in one ear for four weeks, the deafness being accompanied by a distressing feeling of fullness in the head. She brought a note to the effect that her medical adviser had employed Politzer's method of inflation and the catheter but without any improvement in the hearing. The tympanic membrane was much indrawn, but did not show the typical appearances indicating serous effusion, having extensive calcareous changes both behind and in front of the malleus. Politzerisation was almost without effect and the catheter produced but very slight improvement. It was only when I punctured the membrane with a suction exploratory needle and drew out a few drops of clear fluid that the nature of the condition was established and relief was obtained. A free incision in the postero-inferior part of the membrane brought about almost complete restoration of hearing.

The suction exploratory needle differs from those previously employed in being attached to a U-shaped glass tube furnished with a piece of indiarubber tubing and glass tip for the explorer's mouth. The interposition of the indiarubber tube for aspiration gives a greater degree of delicacy than a syringe can give even in the most skilful hands. The glass U-tube acts as an efficient handle, and if the proximal limb is shorter than the distal one the view is as little impeded as possible. In addition, the upper portion of the mount of the needle is flattened down (see Figure).

In a case of epithelioma of the right side of the nasopharynx, complete deafness with distressing fullness in the corresponding ear occurred. Relief was immediately afforded for a time by aspiration with this needle, the fluid extracted being clear (serous) and sterile. The condition was one of *hydrops e vacuo* from mechanical occlusion of the Eustachian tube, with absorption of the contained air. The relief was only transitory but was quite appreciable and it was obtained again from time to time on a repetition of the puncture.

Another case was that of a musician for whom was removing nasal polypi in several sittings an whose left ear had almost suddenly got quite dea The membrane was indrawn and showed a greenisl golden sheen. Inflation produced little or no effec but when I withdrew a few drops of clear fluid wit the exploratory needle the hearing improved an after a free incision, became normal. A temporar

Suction exploratory needle.

closure of the tube, inflammatory or traumatic, ha evidently led to the development of the *hydrops vacuo* of Bezold.

Such cases, if not very rare, are certainly not ver common and their nature is apt to be unrecognise by those who associate an effusion into the tympanu with bulging of the membrane, or who look for th typical black line of the level of the fluid, which not present when the cavity is quite full and n visible when the membrane is opaque. A greenisl golden tint with a shiny surface may suggest th presence of an exudation. A myringotome will sett the question at once, but many patients dread th cutting of the membrane and when the diagnosis uncertain the practitioner may hesitate to make th cut. A prick with an exploratory needle is mo readily permitted, and I venture to recommend th one I have described as the most convenient I ha come across.

A lady of a certain age who consulted me o account of what was found to be a serous effusio into the middle ear insisted on being treated witho incision of the membrane. Whether she would ha allowed an exploratory puncture with the needle, do not know. I introduced, however, a Weber-Lie tube through the Eustachian catheter, and by mea of a large ear-syringe inserted into the Weber-Li tube withdrew a few drops of clear fluid. After a fe repetitions of the procedure the hearing returned normal. It is difficult to decide how much of th good result was due to the suction and how much t the dilatation of the Eustachian tube, but probab some to each.

It may be asked why a puncture of the drum ofte

makes such an immediate improvement in cases in which inflation by either Politzer's air-bag or the Eustachian catheter has been unavailing. When the amount of fluid is small and the vacuum not very perfect, the inflation of air may disperse the fluid into the accessory cavities as well as out by the Eustachian tube, but when the tympanum is full "to capacity," such inflation may produce compression without displacement. The negative pressure in these cases must be very high and must exercise its suction action on the walls of the Eustachian canal, drawing them together and increasing the tightness of the occlusion. Puncture of the drum relieves the negative pressure at once and breaks the "vicious circle" if only for the time. Along with the transudation of fluid there is produced a swelling of the mucous membrane and it is obvious that if relief is not quickly afforded the liquid will become inspissated while the mucosal swelling becomes more organised. There are, then, all the elements required for the production of the so-called chronic catarrh of the middle ear.

This condition has, therefore, an importance of its own as compared with acute suppurative inflammation in which, after the rupture of the membrane, the parts often return to their normal condition. The necessity for early detection of the serous effusion or serous catarrh is, therefore, very obvious, and I think we are better armed for this purpose with such an exploratory needle as the one I recommend.

RETROPERITONEAL HÆMORRHAGE.

A REPORT OF TWO CASES.

By T. G. Illtyd James, M.B. Wales, F.R.C.S. Eng.,

SENIOR RESIDENT MEDICAL OFFICER, PARK ROYAL HOSPITAL.

Retroperitoneal hæmorrhage, causing symptoms necessitating surgical intervention, is uncommon, and these cases are recorded to illustrate some of the difficulties in diagnosis and treatment.

THE FIRST CASE.

Traumatic Retroperitoneal Hœmorrhage; Duodenal Obstruction.—A man, aged 26, was admitted to hospital on July 18th, 1930. In attempting to stop a runaway horse and cart he was thrown to the ground and run over. On admission he was suffering from a moderate amount of shock. Temperature, 98·4° F. Pulse-rate, 88. There were abrasions over the sacrum and buttocks. No other abnormality was detected. On the following day he complained of a dull abdominal pain to the right of the umbilicus, associated with tenderness and slight rigidity in the right upper quadrant of the abdomen. The pulse and temperature were normal, and a diagnosis of contusion of the abdominal wall was made. The pain diminished with rest, and as there were no symptoms for four days he was allowed up on July 23rd. The next day he complained of a return of the pain, worse after taking food, and he vomited on two occasions. The pulse and temperature remained normal and there were no signs of peritonitis. The symptoms increased in severity and he vomited large quantities of greenish fluid on several occasions. On July 29th a mass was felt to the right of the umbilicus, the size of a small orange. The swelling was fixed and did not move with respiration. It was not in relation with the liver or the right kidney. The physical signs, with the history and symptoms, suggested a retroperitoneal swelling compressing the duodenum.

On July 30th the abdomen was opened by a right paramedian incision. A fluctuating swelling, the size of a tennis ball, was found behind the third part of the duodenum, obviously compressing its lumen. The peritoneum over the swelling was incised and blood-clot was evacuated. The right kidney and the head of the pancreas appeared normal and no bleeding-point was found. A very firm abdominal binder was applied after closure of the abdomen. Convalescence was uneventful and the patient was discharged on August 20th. There has been no return of symptoms.

The salient features of the case are: (*a*) nature of the injury; (*b*) development of the hæmatoma after allowing the patient to resume activity; (*c*) nature of the vomit—greenish fluid gradually increasing in quantity—consisting of stomach and duodenal contents only; (*d*) nature of the pain, aggravated by food and relieved by vomiting; and (*e*) absence of any sign or symptom of intraperitoneal hæmorrhage or peritonitis.

THE SECOND CASE.

Spontaneous Retroperitoneal Hœmorrhage; Cirrhosis of the Liver.—An unmarried woman, aged 36, was admitted to hospital on Oct. 30th, 1928, complaining of general abdominal pain and vomiting of one day's duration. She had suffered from similar "bilious attacks" for about 12 months. They were not sufficiently severe to interfere with her work and had no relation to food. There were no features worthy of note in the personal or family history.

The patient was a thin, pale woman with a lax abdomen, free from tenderness. The lower border of the liver was easily palpable and the kidneys freely movable. Barium meal showed a moderate degree of visceroptosis. Investigation of the renal tract showed no abnormality. The Wassermann reaction was negative. A diagnosis of visceroptosis was made and suitable treatment instituted.

On Nov. 7th she was suddenly seized with severe abdominal pain and vomiting. The abdomen was tender and rigid all over. Temperature was subnormal and the pulse rapid and feeble. The appearances suggested an "acute abdomen," and laparatomy was performed. There was an extensive retroperitoneal hæmorrhage with hæmorrhagic infiltration into the mesentery of the small intestine and the transverse colon. The retroperitoneal veins were greatly dilated. The liver was moderately enlarged, with the characteristic granular surface of cirrhosis. The other abdominal organs were normal. No blood or free fluid was found in the peritoneal cavity. The abdomen was closed. After a slow convalescence the patient was discharged on Dec. 13th. The patient was seen one year later; she was still subject to occasional attacks of abdominal pain and vomiting but there was no change in her general condition. A history of alcoholism was subsequently obtained.

The important features of the case are the absence of definite signs of portal cirrhosis, the unusual site of the hæmorrhage, and the fact that the symptoms simulated those of an acute intra-abdominal lesion.

DISCUSSION.

Osler [1] has pointed out that the most extreme grade of portal cirrhosis may exist without symptoms; so long as the compensatory mechanism is maintained the patient may suffer no inconvenience. The veins of Retzius unite the radicles of the portal branches in the intestine and mesentery with the inferior vena cava and its branches. To this system belong the whole group of retroperitoneal veins which are, in many instances, enormously enlarged, particularly about the kidneys, and carry a considerable proportion of the portal blood. It is probable that in the case reported the hypertrophy of the retroperitoneal veins produced a compensatory mechanism sufficient to account for the latency of the symptoms. Hæmorrhage from mucous surfaces is a common manifestation of portal cirrhosis; the bleeding usually occurs at the site where the stress on the collateral circulation is greatest.

Hæmorrhages in the anterior abdominal wall have been recorded, and Carnot [2] has described hæmorrhages associated with cirrhosis of the liver in the psoas and rectus abdominis muscles, with great enlargement of the para-umbilical veins. It is uncommon for such hæmorrhages to be unassociated with more obvious bleeding and with evidence of a collateral circulation.

As in the case recorded, retroperitoneal hæmorrhage may give rise to symptoms and signs of some grave

intra-abdominal lesion. It is probable that vomiting, abdominal rigidity, meteorism, shock, and so on, are due to interference with the nerve plexuses in the retroperitoneal tissues and in the mesenteries. If the hæmorrhage is extensive it will give rise to symptoms by mechanical obstruction and by the loss of blood. Diagnosis is usually possible only after the abdomen has been opened, and then the hæmorrhage is best left alone, unless it is producing mechanical obstruction, when the clot should be evacuated. The general condition of the patient would probably be such that any of the usual methods of reinforcing the existing collateral circulation in portal cirrhosis (with the possible exception of including the great omentum in the parietal incision) would not be entertained.

Traumatic retroperitoneal hæmorrhage, although rare, is more common than the spontaneous variety, and cases have been recorded by Choquard,[3] Schneider[4] Summers,[5] and Hinton.[6] It usually results from direct trauma, as by blows, falls, or run-over accidents. Compared with the more serious results of such trauma—intraperitoneal hæmorrhage from injury to a solid organ, or peritonitis from rupture of a hollow viscus—retroperitoneal hæmorrhage is rare (2 out of 53 cases discussed by Hinton). The bleeding usually arises from some small retroperitoneal vessel and may be diffuse or localised. Diffuse hæmorrhage gives rise to symptoms described under Case 2. Localised hæmorrhage will form a tumour-like mass which may compress the least mobile parts of the intestine and cause symptoms of intestinal obstruction. Retroperitoneal hæmorrhage due to injuries to the kidney can usually be diagnosed by the physical signs and examination of the urine.

Retroperitoneal inflammation due to injuries to the duodenum or colon gives rise to a cellulitis of great severity, with early rise of temperature and the rapid formation of an emphysematous inflammatory swelling in the loin. Diffuse hæmorrhage is usually diagnosed after the abdomen has been opened for a suspected injury to some intra-abdominal organ. The bleeding-point is usually not found and the cases are best left alone. Localised retroperitoneal hæmatomas should be evacuated by incision, for they usually cause symptoms from pressure on the gut, or at a later date they may give trouble as retroperitoneal or mesenteric "cysts."

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF NEUROLOGY AND OPHTHALMOLOGY.

AT a joint meeting of these Sections, held on Nov. 13th, the chair was taken by Mr. LESLIE PATON, President of the Section of Neurology. Dr. A. LINDAU opened a discussion on

Vascular Tumours of the Brain and Spinal Cord.

These growths, he said, had an importance greater than their numerical occurrence would suggest. Their division by Cushing and Bailey into two groups—angiomatous malformations and hæmangioblastomata—marked a great advance, as the site, histology, signs, and treatment were different in the two groups. The telangiectases, which might be found deep in the brain stem, were rare and unimportant. Venous and arteriovenous malformations were usually in the cerebrum, but might be found lower in the brain or in the cord. They consisted of numerous wide blood-vessels with intervening glious tissue. Angiomatous malformations always showed these traces of compressed nervous tissue between the vascular loops, and were associated with a systemic disorder characterised by trigeminal nævi, homolateral pial angioma showing calcification when examined by X rays, and a unilateral buphthalmus or glaucoma. The syndrome often occurred in young children but a family history was only occasionally found. In France the condition was known as "syndrome névrocutané."

Quite different in type was the hæmangioblastoma, known in France as "angioréticulome." This was essentially neoplastic, with a characteristic microscopical appearance. It was not rare; Dr. Lindau had met 17 cases. It usually occurred in the cerebellum and sometimes in the medulla or cord, but not in the hemisphere. It might be either compact or cystic, and a cyst often showed a nodule in its wall. Often the colour was yellow. The structure seemed to be that of a nævus, but there was abundant intercapillary tissue, usually rich in pseudo-xanthoma cells. These were due to exudation of lymphocytes containing lipoids and their ingestion by the phagocytic endothelial cells. The characteristic foam cells were due to lymph stagnation. Nervous tissue—owing to its lack of lymphatic vessels—was unable to get rid of the fluid produced by the tumour and as these hæmangioblastomata were very exudative cyst formation resulted. Hæmangioblastomata in the hind-brain might arise from a vascular anlage in or near the fourth ventricle.

The underlying process at work might give rise to a general capillary angiomatosis of the central nervous system, with vascular tumours in the retina and hind-brain and growths in the pancreas and kidney. This syndrome revealed a family history in 20 per cent. of cases. The growths in the abdominal organs were benign and were only revealed at post mortem. The histological picture was often obscure and the lesion could only be identified in fresh specimens. Perdrau's staining was of great value. Local treatment of the brain condition was likely to be successful, but the possibility of other lesions must always be borne in mind. The relationship between angiogliomata, angioblastic meningiomata and hæmangioblastomata required further research.

SURGICAL TREATMENT.

Sir PERCY SARGENT said that the grouping of vascular tumours into divisions must not be too closely insisted upon. It was hard to tell arterial from venous growths in the brain, and better not to try. The growths belonged to the pia mater and

were usually superficial. X rays might reveal calcified vessels. It was difficult to know how to treat them. Ligature might cause a temporary increase in paretic symptoms and—like ligation of the carotid—gave little benefit. Death usually resulted from hæmorrhage.

In the cord the vessels seemed to be venous; as in the cerebral type, there was a curious matting of the arachnoid. The variability in the symptoms was characteristic; grave attacks might be followed by long periods of intermission with conspicuous improvement. The cerebro-spinal fluid in three of his cases had been golden-yellow and had shown a slight increase of protein. The intermissions made it difficult to estimate the value of treatment. Opening the theca might be beneficial, but the symptoms were not wholly due to mechanical pressure; they were partly caused by circulatory disturbance in the cord. Ligation was harmless but ineffective. He described a curious case of thrombosed aneurysm of an artery of the pia mater, which had caused signs indicating a tumour in the region of the seventh cervical. Laminectomy had caused such profuse hæmorrhage that the operation had had to be abandoned. Autopsy revealed a kind of cirsoid aneurysm involving the cervical muscles, the vertebræ, and the membranes.

Capillary nævoid growths in the pia and choroid came between hæmangiomata and hæmangioblastomata. Cysts constituted 10 per cent. of all intracerebellar tumours. Simple serous cysts were often seen in museums, but it was probable that some of these contained overlooked hæmangioblastomata. Parasitic cysts occurred, and Virchow had described a developmental cyst in connexion with the fourth ventricle; hæmangiomata or gliomata, however, probably accounted for the majority of cysts.

ANGIOMATOUS FORMATIONS IN THE EYE BALL.

Mr. TREACHER COLLINS said that congenital abnormalities were found in the retinal and in the ciliary vessels. Those in the retinal vessels were either angiomata—composed of fully formed vessels—or angioblastomata, composed of the cellular elements of blood-vessels and genuinely neoplastic. In angiomata the vessels were remarkably tortuous and there was often an associated facial nævus and sometimes symptoms of pressure on the cerebrum. Angioblastomata were characterised by a raised mass in the periphery of the fundus to which led a dilated artery and vein. Cerebellar vascular cysts were often present as well. The growth was a mesoblastic neoplasm growing in a neuro-epiblastic structure. Sometimes the endothelial proliferation exceeded the vascular formation and a hæmo-angio-endothelioma resulted. The characteristic appearances were due to the fact that the retinal arteries were end-arteries. The affection was always progressive and ended in blindness. The presence of tortuosity in the retinal vessels might assist the preoperative diagnosis of doubtful cases of cerebral tumour and of recurrent epistaxis.

In the choroid, angiomata occurred in the posterior ciliary vessels. They were usually cavernous and associated with vascular nævi on the face. They were apt to develop a fibrous or osteotic membrane round them; this might be compared with the opaque capsule sometimes seen by X rays round cerebral angiomata. Sometimes the anterior ciliary blood-vessels were involved in facial angiomatous formations, and in this case the canal of Schlemm was obliterated and the iris thickened. This meant obstruction and glaucoma; if the glaucoma occurred early in life the eye became buphthalmic. Cases of this kind were sometimes associated with contralateral epileptic symptoms.

Ocular symptoms might be caused by intracranial hæmangiomatosis apart from any growth in the eye itself; for example, papillœdema from pressure or homonymous hemianopia from involvement of the visual cortex.

Dr. J. G. GREENFIELD said that angiomata were usually congenital and often remained the same size throughout life. They might occasionally become sarcomatous. The term "hæmangioblastoma" postulated a growing tumour, and small tumours which were not liable to grow were better called capillary hæmangiomata. The tumour might lie latent until some trauma caused seepage which led to cyst-formation. He showed specimens and slides illustrating the congenital nature, the family history, and the presence of more than one tumour in the patient.

THE CLINICAL PICTURE.

Dr. GEORGE RIDDOCH discussed the clinical picture of intracranial hæmangioblastoma. The diagnosis, he said, rested on the age and the early intermittent hydrocephalic headache, which occurred early in the morning, often woke the patient up, might be brought on by coughing or sneezing, was sometimes associated with abnormal sensations, and was shooting in character. Characteristically late was the appearance of papillœdema and cerebellar signs: giddiness on movement of the head or staggering. Nystagmus, dysmetria, and hypotonia might not appear until the disease was well advanced. The interval between the onset of headache and the appearance of cerebellar signs was shorter with cystic than with solid tumours, and the course of the cystic syndrome was apt to be rapid once symptoms had appeared. The headache appeared earlier in the solid than in the cystic case. Dr. Riddoch described a case of intracranial hæmangioblastoma in a tram conductor, aged 24, who had had an epileptiform seizure with sensory loss, aphasia, and bilateral papillœdema. Operation had revealed a cyst in the left hemisphere with a small reddish-brown plaque in its wall. After deep X ray therapy the man had returned to work.

Dr. DOROTHY RUSSELL described cases from the pathological museum of the London Hospital. The serpentine angioma or arteriovenous aneurysm occurred in the lepto-meninges and extended to the brain. It had no capsule, and the interstitial tissue was a fine reticulum. A Mallory's preparation showed tongues of glia extending into the tumour, but the greater part was devoid of glia. In one case of capillary hæmangioma there was a well-developed syringomyelia in the cervical enlargement and extending below as far as the tenth dorsal. One case showing multiple telangiectases illustrated a condition which was probably a precursor of cavernous hæmangioma. The cavernous type usually occurred above the tentorium, as a solitary area in which blood-vessels of various sizes were packed closely. There was no anatomical connexion with the meninges; the growth was not cystic and formed a non-encapsulated system of capillary and cavernous spaces, often separated in the outer part by glia and surrounded by gliosis. The walls were made of collagen lined with a single layer of cells and without any trace of muscular or fibrous tissue. The presence of glia was not, however, a good criterion for distinguishing these growths from

the serpentine type. In one case bone trabeculæ were found in the collagen. Endothelial proliferation might be a distinguishing criterion, but some cases had been described in the cerebellum without this proliferation. These had affinity with capillary telangiectases and might be derived from them by organisation of spaces and fusion of walls. Capillary telangiectases were, however, very rare compared with cavernous hæmangiomata, which formed a distinct group. Their relation with Lindau's group was at present doubtful.

Mr. L. BATHE RAWLING described cases that he had seen. In one, headache and fits had been relieved by decompression, but five years later the patient had had an enormous hæmatoma on his right frontal region. This had been cured in time. Possibly decompression prevented a subdural hæmorrhage, but laid the patient open to subcutaneous bursting of the vessels. Another case had had a congenital weakness of the left side, with fits, and a large angioma on the right side of the face. X ray revealed an angiomatous condition with calcified vessels in the right half of the cerebrum and an enormous mass in the occipital region extending deeply into the substance of the brain. Radium treatment had been instituted.

Dr. PARKES WEBER said that the racemose meningeal angioma above the tentorium was usually associated with a port-wine stain on the skin, and asked what cutaneous lesion was associated with Lindau's disease—hæmangio-endotheliomata mostly below the tentorium. He would expect the hæmangio-endothelioma or hæmangio-xanthoma which was common in children. The cysts in the kidney were not those of polycystic disease—which he preferred to call congenital cystic dysplasia of the kidney and liver because the associated condition of the liver was often fibrous rather than cystic.

Dr. HENRY COHEN drew attention to some radiological features. He described a case of a boy of 14 who developed epilepsy and at the age of 25 showed a left hemiparesis with signs of right parietal tumour, but without papillœdema or headache. A bruit heard over the right parietal eminence was synchronous with systole and was obliterated by pressure on the carotid. Radiograms showed a depression in the skull with diploic veins radiating from it. Another patient with a similar bruit had left-sided Jacksonian epilepsy with a large port-wine stain over the whole left side of the body and a port-wine nævus on the left side of his face. He had developed a right hemiparesis at the age of 38. The X ray showed areas of calcification on both sides of the skull.

Dr. W. G. BARNARD showed a unique specimen: a capillary hæmangioma above the tentorium. This resembled Dr. Riddoch's case, and Dr. Barnard thought that the condition was only rare because the interest in it was of recent date.

Dr. LINDAU, in reply, agreed with Dr. Greenfield that trauma must have some importance, but could not agree that the growths were congenital. They could be seen developing in the eye. He could not answer Dr. Parkes Weber's question about the cutaneous lesion, because only two cases had been reported and no histological details had been given. He agreed that the renal cysts in the Lindau syndrome were not of the polycystic type; there would be only 10 to 20 small scattered cysts, while the pancreas would be full of them.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

AT a general meeting of this Association held on Nov. 7th, with Dr. G. E. FRIEND (Christ's Hospital) in the chair, a discussion on

Appendicitis, Acute and Chronic, in the Schoolboy

was opened by Mr. L. E. BARRINGTON-WARD, whose remarks appear in full on p. 1116.

Dr. FRIEND said he had understood Mr. Barrington-Ward to say that in acute appendicitis the condition was usually obstructive from the start. He had wondered whether, in the subacute type, there was a pre-obstructive stage which was diagnosable. Of 105 cases diagnosed in his school during recent years 11 were operated upon in the school and 89 at home. Of the school cases, seven showed appendix abscesses, and four acute catarrh which might have quieted down without operation. Of the 89, 78 were diagnosed at school and were watched; symptoms subsided in two or three days, but the tongue remained furred, and there was persistent tenderness in the right iliac fossa; operation at home was advised, and in 77 out of the 78 some abnormality of the appendix was found. In one case the appendix was thickened and a small quantity of pus was found shut up in the lumen, but the boy had shown no signs suggesting abscess after the attack. It appeared that the 78 cases which quieted down could not have been obstructive from the outset. Might there not be an acute catarrhal condition which could be diagnosed if seen early? Boys, unfortunately, did not care to report sickness in the early stages. Statistics for Christ's Hospital since 1889 showed a steady increase in the number of cases of appendicitis diagnosed and a reduction in the number of "disordered stomachs." He thought subacute cases could be diagnosed in the pre-obstructive stage by the facts that the pain was not always localised, and that there was often no vomiting; furred tongue and tenderness on deep pressure over McBurney's point persisted after the attack. His treatment of these cases consisted of rest in bed, and castor oil. The pulse and temperature were taken two-hourly and if there was no improvement he asked for a consultation. If there was improvement he gave a following dose of senna and a light diet. He was aware that opinion was against the use of castor oil, but he had never found it to be harmful.

DISCUSSION.

Sir BRUCE BRUCE-PORTER was of the opinion that attacks of appendicitis always began in childhood and were put down to some error of diet. He had always found enlarged tonsils present in patients with appendicitis and believed the two were connected. Incontinence developing in boys after a bad bilious attack was usually due to an inflamed appendix in contact with the bladder. The sudden onset of dysmenorrhœa in girls might sometimes be traced to a similar irritative effect of a diseased appendix.

Dr. R. A. LEMPRIERE (Haileybury) found an objection to glucose and saline given rectally immediately after operation; the previous constipation made a wash-out desirable before giving glucose, but this was liable to stimulate peristalsis at a time when the incised cæcum required rest. It had not been his experience, moreover, that the pulse was invariably raised, and he quoted the case of a boy at Haileybury who had shown no physical signs until late in the

attack. The difficulty, in his opinion, lay with the mild, slight cases, without rise of temperature or vomiting and with only slight tenderness. In these he advised taking the pulse and temperature every half-hour, and asking for a consultation as soon as there was the slightest rise. He was strongly of the opinion that nothing should be given in the meantime, and in any event never castor oil. If the boy vomited without relief of pain the parents should be warned; even if the case appeared to be mild, operation should be advised, as frequently the condition was found to be more serious than had been anticipated before the abdomen was opened. The expense of the operation was often a heavier burden to parents than surgeons realised. He could only think of two cases in which tonsillitis had preceded the attack. Although cases were now seen comparatively early it was seldom less than 12 hours from the onset that advice was sought; acute cases often appeared to begin during the night.

Dr. S. P. HUGGINS (Wycombe Abbey) said that inflammation of small glands round the cæcum sometimes gave rise to doubtful symptoms; there might be pain and tenderness with a slight rise of temperature, simulating appendicitis. It had recently been suggested that the condition was due to an infected cæcum, but it was only occasionally possible to make the diagnosis without operation. He had used glucose and saline rectally following operation for a long time past. He usually tried to arrange for the bowel to be emptied before operation by means of a wash-out. Where castor oil had been given he always rebuked the mother, but nevertheless it often had the effect of bringing things to a head. A raised pulse-rate was important; he quoted a case where the temperature was at first slightly raised and then averaged normal, while the pulse remained at 90; operation revealed a diseased appendix. In his experience children with acidosis sooner or later developed appendicitis. In doubtful cases where the appendix was found to contain nothing but fæcal material was it possible that it had been removed in a stage preceding the inevitable development of disease?

Dr. W. ATTLEE (Eton) pointed out that no single sign or combination of signs and symptoms gave a reliable indication of appendicitis. It was therefore dangerous to diagnosis any case as catarrhal and to postpone operation. Early operation had everything to recommend it; some normal appendices would certainly be removed, but many would prove unexpectedly to be seriously affected. Tuberculous glands and sometimes enteric might give rise to errors in diagnosis.

Dr. HUGGINS quoted a case where a young girl had acidosis and developed an attack of appendicitis. Operation was postponed for 14 days and then a small abscess was found. Her pulse remained rapid for six months afterwards, which he thought a sufficient contra-indication of delayed operation.

Dr. FRIEND said he had never known an appendix abscess to develop among the cases which he had watched, except in the case already quoted of the boy whose symptoms subsided completely in 24 hours; operation at home was advised, and a small quantity of pus was found encapsulated in the appendix. A competent surgeon had refused operation in the acute stage. He never postponed operation in cases where the diagnosis was certain.

REPLY.

Mr. BARRINGTON-WARD said he regretted the zeal shown for castor oil. It was possible to tell when oil had been given by the speed with which the appendix burst. He had known many cases where it might have been removed clean if castor oil had not been given and provoked rupture. There were probably some cases where secretion in the lumen of the appendix gave rise to peristalsis and pain, associated with furred tongue and slight tenderness. There had been so much abuse of appendix operations in the past that he preferred to wait for more definite symptoms than those. Large tonsils certainly went with appendicitis in many cases. As for glucose, he preferred to give it as a solution and not with saline; it was absorbed readily as a solution and did not tend to increase the patient's thirst. It was useful if an enema could be given before the operation, but if this was not possible a good nurse should have no difficulty in getting the solution absorbed. Four-hourly enemata of 6 to 8 oz. might be given rather than a continuous injection if there was any difficulty. He had not intended to be dogmatic when he said the pulse was always raised; it was an important sign in deciding whether the child was ill or not, but there were certainly some cases in which there was not much rise, usually in children who had normally a slow pulse-rate; it was therefore valuable to know the normal rate. He was interested in the sign described by Dr. Lempriere—namely, the absence of relief of pain after vomiting. He had not previously been aware that inflamed glands round the cæcum could simulate appendicitis, though they were frequently seen at operation. The differential diagnosis from tuberculous glands was always a pitfall, but one which could more often be avoided as experience increased. With paratyphoid confusion often arose, but the temperature was usually unduly high and tenderness was often fleeting. In appendicitis once the symptoms developed they went steadily on without remissions.

HUNTERIAN SOCIETY.

AT a meeting of this Society on Nov. 17th, with Prof. A. W. SHEEN, the President, in the chair, a discussion on the

Place of the Doctor in Industry

was opened by Sir DAVID MILNE-WATSON, Governor of the Gas, Light and Coke Company. After an historical introduction, he pointed out that the question to-day was how the doctor could help industrialists to solve the human problems which they had to face. They were becoming more and more interested in what medical men had to say about making the factory and workshop more hygienic, and the work less fatiguing and monotonous. A very important part of the function of the doctor in industry was to examine the man entering upon employment. In former days a man was engaged without medical examination, and often the work proved to be of a kind to which he should never have been put. The most enlightened firms to-day had every candidate for employment medically examined; this was a great advantage to the man himself and a great saving to the employer. The doctor also undertook periodical examinations of the workmen, but these should not be too frequent. It was clearly the duty of industry to provide light, sanitary workshops, to make the lives of the workers as varied as possible (though this was very difficult in these days of process working), and to do whatever possible to eliminate unnecessary fatigue. Attention must also be given to means of recreation, and his own company also provided baths and ambulance rooms. At the same time it must always be remembered that the most important part

of the life of the workman was lived, not in the factory, but at home. Over the home conditions the industrialist could have little influence, and it was here that the help of the medical profession was most valuable.

Mr. W. A. APPLETON, secretary of the General Federation of Trade Unions, said the doctor's great concern must always be with the individual man or woman, and the first step was the development of a personal relationship with his patient. Modern legislation had affected that relationship, and threatened to affect it more. Formerly the doctor was under obligation only to his own honour and to the sick person; to-day he was also under obligation to the State, which expected from him a considerable amount of clerical and statistical work which irritated him and might even militate against personal study. When to State regulation and bureaucratic direction were added changing expressions of invalidity and so forth, people had indeed cause to be perturbed. They might well wonder whether the practitioner would be able to satisfy administrative requirements, to keep in touch with pathological discovery, to do his duty to the patient, and to pay attention to the interests of the community so far as these were bound up in industry. Modern conditions and demands did indeed seem to be placing a great deal upon the doctor, and, looking at the matter from an outsider's point of view, it did not appear that the doctor could, with credit to himself or profit to his patient, wander so far outside his own particular sphere as he was often expected to do. He might be intellectually interested in the whole scheme of industry, and he must be conversant with conditions leading to ill-health, but he would best promote its efficiency by promoting the health of those employed.

Prof. E. L. COLLIS maintained that the duty of the medical man, on examining those who applied to enter industry, was not like the duty of the medical man examining recruits for the army. In the latter case he had to refuse the unfit, but in the case of industry what he had to do was to find out to what work the unfit could be put. The conditions in industry were so varied that work could be found for the halt and the blind as well as for the physically capable. The first thing that the doctor had to do was to try to provide the industrialist with people fitted for the various kinds of work for which the industry called. Until recently—up to the beginning of the present century at any rate—he had always felt that one of the things which was doing most harm to general health was the condition of life in the factories. Even at that time some attempt was made to teach the child the rules of health, but when that child, having some ideas as to the necessity for cleanliness and so forth in relation to health, left school and went to the factory, he found sanitation then wholly neglected. A great improvement had been made in this respect of recent years, and it was from the factories, when the hygienic work was properly organised, that the great rules of hygiene could be carried into the home. One of the results of the entrance of medicine into industry was the decrease of labour turnover—by which he meant the flitting of worker from factory to factory. A factory employing about 1000 people might well in the course of a year engage 1000 people to keep its staff at the same level—that is to say, while a number of workers in the factory remained there continuously, there was a constant drift of casual labour moving in and out. A labour turnover of 100 per cent. per annum was not at all unusual, and more than half the accidents in the factory, and also the sickness absenteeism, occurred amongst those who were employed there for periods of six months or less. There were still far too few firms which organised medical services for their employees. There was in London a society of doctors employed by industrial firms; its membership was less than 50, and it included most of the industrial physicians who were at work. In his belief not much more than 20,000 people worked in industries where there was supervision by whole-time doctors in the industrial service. This figure compared disadvantageously with America, where 2,000,000 workers were said to have this advantage.

Dr. STRICKLAND GOODALL said it was the doctor's duty in the first place to ensure the recruiting of healthy material. It was a great mistake to recruit anything else. By recruiting only healthy people, all the healthy would gradually be absorbed into industry, and unemployment and unfitness would become synonymous terms. The examination of the recruit should be undertaken from three standpoints: (1) to see if he was physically fit; (2) to see whether he was suitable for the kind of work he was going to do, which involved technical knowledge of the work on the part of the doctor; (3) from the point of view of the dominant disease, which to-day was cardiovascular disease. In 1911 there were 53,000 deaths from cardiovascular disease, and 15 years later the number had risen to 85,000. The main object of examining recruits was, of course, to ensure efficient workmen and to carry on the industry with a minimal amount of off-duty time. From the recruit's point of view it was entirely advantageous, because it prevented him from wasting his time learning a job he would never be able to do satisfactorily. Dr. Goodall mentioned that of 61,000 men examined for employment with the London General Omnibus Company, no less than 44 per cent. were rejected. In a works with which he had to do, employing 9000 or 10,000 men, about 21 per cent. were rejected. The second function was the maintenance of the health of the worker. The chief methods consisted of teaching the principles of general hygiene, first aid, periodical examinations—not too frequent, but systematic—inspection of buildings or ships as the case might be, arrangements for convalescent care when necessary, and generally the giving of advice about recreational provisions.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY

A MEETING of this Society on Nov. 5th, with Prof. GRAHAM SIMPSON, the President, in the chair, was devoted to a discussion on

Chronic Abdominal Pain.

Dr. E. F. SKINNER put forward two generalisations about pain: (1) its intensity varies inversely as the nervous stability of the individual, which may be diminished by illness; (2) its significance varies inversely as the richness of its description. He had been struck by the fact that the patients who most complained of pain suffered from functional rather than structural organic disease. As a physical sign pain could only be useful when it recurred frequently enough in different people under similar conditions to make it recognisable. It was often an uncertain guide-post. He suspected that appendicectomy was often done merely on the grounds of chronic abdominal pain. The only pain which was really of diagnostic aid was the type of referred pain which had definitely anatomical localisation.

Mr. E. F. FINCH said that from a clinical point of view pain could be regarded as due to tension. The

spontaneous abdominal pain complained of by a patient was usually vague and very ill-defined. It might become more localised as the peritoneum became involved but then was usually accompanied by physical signs. Pain being a purely subjective symptom there was a natural tendency to refer the patient at once to the radiologist or biochemist for further tests, and thus one of the most important methods of examination—namely, a careful clinical history—was apt to be neglected. The question of operation for chronic abdominal pain with no physical signs was a matter of weighing evidence, and in arriving at a decision the most valuable opinion was that of the family doctor.

Mr. W. W. KING described pain as the most valuable of objective symptoms. When due to retroversion or prolapse it was relieved by lying down. If due to pelvic inflammation, endometrioma, or the malignant invasion of tissues, it was not much influenced by posture, and might even be worse at night. Recurrent pains were generally intestinal rather than uterine in origin. Retroversion—actual, partial, or imaginary—had been blamed for much pelvic pain, but pain associated with retroversion was not necessarily caused by it. In Mr. King's opinion a mobile retroversion did not cause pain in nulliparæ or in women after the menopause. Most retroversions in parous women did not cause pain, but some did. The pessary test was valuable in such cases. If the pain was relieved and recurred after the removal of the instrument, operation could be confidently advised. If the pessary test was not applicable to a particular case, operation might give relief but it was uncertain. Endometrioma was one of the commonest and the least generally recognised causes of abdominal pain. The large masses were easily recognised, but a small nodule often caused great suffering.

Dr. JOHN WILKIE showed skiagrams and gave the clinical history of cases of abdominal pain caused by lymphatic leukæmia, syphilis of the stomach, malignant growth of the lung, calcification of the pleura, and osteo-arthritis of the spine.

Dr. A. G. YATES said that it was important not to forget that chronic abdominal pain might be due to diseases outside the abdominal cavity. Persistent pain was sometimes due to panniculitis. The thick folds of subcutaneous fat felt indurated and might be mistaken for a more deep-seated lesion. It was a good rule always to examine the pupils and the reflexes in cases showing abdominal symptoms. The abdominal crises of tabes might simulate gastric, duodenal, or other lesions. Nerve-root irritation by tumour or spinal caries were other possible sources of error. The functional cases, and especially those of so-called visceroptosis, were perhaps the most difficult of all. They were good examples of Adler's organ inferiority. The poor abdominal development, narrow chest, and acute subcostal angle with displacement downwards of the abdominal viscera constituted a perfect nidus for the development of a psychoneurosis, and the pain in these cases, though real, was psychological and constituted a means of escape from some intolerable situation.

Dr. ARCHIBALD YOUNG spoke of the humiliation which the practitioner felt in ascribing pain to some undetermined gastric disorder. It was often the way of least resistance to accept the patient's own diagnosis of a "gastric stomach." Exact diagnosis by means of X rays and fractional test-meals was impracticable for all cases, but years of practice developed a clinical intuition which enabled one to select the right cases for complete investigation. He believed that chronic constipation was a great cause of pain. It often simulated duodenal ulcer.

Dr. T. H. HARRISON had found that certain types of work were liable to cause abdominal pain. He told of cases in which pain had disappeared on ceasing to work a treadle sewing-machine.

Dr. JAMES MACKINNON said he saw no reason why the analogy of the hysterical knee, where all symptoms often disappeared after an exploratory operation, should not apply to the abdomen. He personally had no experience of such cases. Possibly because there was more to go at in the abdomen he had always found that something was done by the surgeon, but an abdominal operation for "unclear" cases often led to no improvement, and such cases frequently underwent repeated laparotomies.

Dr. R. K. ROBERTSON agreed with Mr. Finch in laying stress on the importance of tension. Probably fewer mistakes would be made if in any case of pain the question was asked if there was anything causing tension in any of the viscera.

Dr. CUTHBERT BARRON pointed out that post-operative pain was often the expression of an anxiety or an exhaustion neurosis in relation to the operation. It was often the sensory nerves at the site of the operation which were disordered. Dyspepsia was the chief cause of pain amongst those who had not been operated upon. Both hypochlorhydria and hyperchlorhydria could cause chronic pain; the former was rare, but the latter was very common.

The PRESIDENT suggested that as the causes of abdominal pain were so numerous and occurred in such diverse regions, the surgeon should cultivate the long abdominal incision after, of course, availing himself of all the resources afforded by X rays and the laboratory.

ULSTER MEDICAL SOCIETY.

AT a meeting of this Society on Nov. 13th, with Mr. HENRY HANNA, the President, in the chair, Prof. LEONARD PARSONS (Birmingham) gave an address on Cœliac Disease. Diagnosis was difficult, he said, because the symptoms came on when the child was about nine months of age and were apt to be attributed to dietetic factors. The diagnosis depends on five main points: (1) passage of large fatty stools; (2) wasting; (3) abdominal distension; (4) anæmia; and (5) evidence of deficiency disease, such as scurvy, œdema, tetany, or rickets. In a few cases xerophthalmia and cataract had been reported. In cœliac disease during its earlier and severer stage rickets was rare; but there was an osteoporosis, which Prof. Parsons regarded as prerachitic. Growth was at a standstill, and although fat absorption was markedly deficient yet enough vitamin D was absorbed to mobilise sufficient calcium and phosphorus to ossify these fragile and atrophic bones. When the diet was corrected, improvement took place and growth started; late rickets might develop, since the absorption of vitamin D was now insufficient for the needs of the growing bone.

Having discussed various theories of causation, Prof. Parsons described the treatment. The diet should be selected from protein milk, skim milk, casein, meat extracts, egg albumin, rabbit, breast of chicken, absolutely ripe bananas, potato crisps, and well-cooked cereals. Some children did better if small amounts of fat were allowed. Any change in

dietary must be made with the greatest care. It was very important to attend to the vitamin deficiency in such a diet. For the anæmia ferrum redactum and brewers' yeast could be given, the value of both of these being due largely to the contamination of copper present. Massage was useful to increase the tone of the muscles, especially of the gluteals and adductors of the thigh, which were especially wasted. In children properly treated the prognosis was quite favourable; genu valgum disappeared and multiple fractures of long standing united. Death was due to intercurrent infections and not to cœliac disease itself.

Prof. W. W. D. THOMSON proposed a vote of thanks, which was seconded by Mr. P. T. CRYMBLE.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held in Manchester on Oct. 24th, with Dr. J. W. BURNS, the President, in the chair.

Dr. A. S. GARDEN (Southport), in a communication on Mouth Infection as a Cause of Puerperal Sepsis, described a series of four cases in the Southport Maternity Hospital of patients developing fever from uterine infection after confinement. The first was delivered normally on Jan. 19th and developed a temperature of 102·6° F. two days later. *Streptococcus pyogenes hæmolyticus* was isolated from a cervical swab. The second case was delivered by low forceps on Jan. 24th and two days later had a rise of temperature. The third case on Jan. 29th developed a rise of temperature on the second day, when the fourth case was confined, and her temperature rose on Feb. 11th. The throats of the entire staff were then swabbed. One nurse was found to harbour hæmolytic streptococci without symptoms. She was isolated from the wards; all members of the staff then wore masks during confinements and swabbings and no further rise of temperature occurred.

In April Dr. Garden had personally supervised a normal delivery with a view to making observations. He found that the acting midwife, who wore a mask, admonished and encouraged the patient with words in which there was a frequent use of sibilants and labial consonants. He concluded that aseptic and antiseptic precautions were better carried out in a maternity hospital than in the home, that the danger from "spray" in institutions is greater because of the elevated labour bed, and that with more assistance there is more talking and "spray." He recommended that in all cases effective masks should be worn.

Dr. Garden also described a case of cancer of the cervix complicating pregnancy, and a discussion followed. Dr. J. W. BRIDE (Manchester) showed a fibroid weighing 14 lb. which he had recently removed, and Dr. C. P. BRENTNALL (Manchester) showed radiograms of general œdema of fœtus and imperfect development of fœtal skull resulting in complete extension of head.

DIAGNOSIS OF MALIGNANT DISEASE OF THE LUNG.—In our account of a meeting of the Medical Society of London last week (p. 1072) Dr. G. Vilvandré is reported as saying: "He did not think carcinoma of the lung would be diagnosed in the X ray room . . ." "What I did say," he writes, "was that I did not think *early* diagnosis of cancer of the lung was made, because the cases were sent so late and the disease was already advanced before the radiologist was asked to see the case."

MEDICINE AND THE LAW.

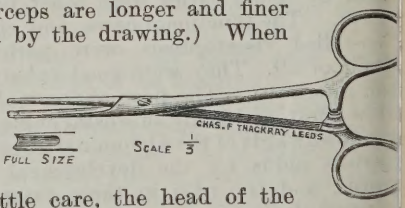
Orthopædics and Faith-healing.

WE described last week the action recently taken by the Stoke-on-Trent Corporation against Pastor Edward Jeffreys, an evangelist, at whose faith-healing meetings splints and surgical appliances were, it was stated, removed from crippled children. The corporation required an undertaking that there should be no interference with the treatment of the children for whose care it is responsible; it also decided to cancel arrangements for the use by Pastor Jeffreys of municipal halls. On Nov. 3rd the town clerk received a letter in which the evangelist explained that his only part with the sick and afflicted who attended his meetings was that of prayer. The letter declared that an open letter had been sent to Mr. Mitchell Smith, the orthopædic surgeon who had conveyed to the corporation the original complaints, with a challenge that "for every one case he can prove is worse I am prepared to bring forward 20 who can testify to physical blessing and healing." The material for examining this latter undertaking is at this stage hardly adequate and the challenge is thus the less likely to be taken up. A more satisfactory passage in the letter declared that, as the Bethel Evangelistic Society was primarily a spiritual movement and as the salvation of souls was regarded as of more importance than the healing of the body, the writer was prepared, "for the sake of the Kingdom of God and the peace of the city," to give his word that he would not touch any leg supports or plasters of any children under treatment by the various authorities of the district. "If it has been done in the past, it has always been with the consent of the parent or some responsible person." The corporation not being satisfied that the promise not to interfere with leg supports, &c., went far enough, the town clerk was directed to write afresh to Pastor Jeffreys. The latter in reply repeated his assurances in a form which the corporation felt itself able to accept. The controversy may therefore, it seems, be regarded as happily ended, and the ban placed upon the evangelist's meetings in local public halls has been removed.

NEW INVENTIONS

RADIUM NEEDLE RECOVERY FORCEPS.

THE purpose of this special pair of forceps is, in the main, to assist in the removal of radium needles. The point of the forceps is as fine as possible, tapered gently, and can be used as a probe. (The jaws of the forceps are longer and finer than indicated by the drawing.) When the head of the needle has been located, the forceps can be opened and, with a little care, the head of the needle can be gripped into grooves in the point. I find these forceps very useful when a needle has become caught in the skin or in the fascial layers, especially if the thread has broken. They are also very useful for inserting radium needles in certain situations, as the point of the forceps themselves can be pushed into the tissue along with the radium needle. The instrument is made by Messrs. C. F. Thackray, of Leeds.



ROBERT R. MORRISON, M.B., Ch.B. Glasg., D.M.R.

REVIEWS AND NOTICES OF BOOKS

Atlas of Pathological Anatomy.

Compiled by E. K. MARTIN, M.S., F.R.C.S. Bristol: John Wright and Sons. 1930. Pp. 487. 75*s*.

FIVE years ago the editorial committee of the *British Journal of Surgery*, under the chairmanship of Lord Moynihan, decided to commence the publication of an "Atlas of Pathological Anatomy" as a supplement to their journal. To quote from the introduction, they realised that "the study of morbid anatomy has of recent years been neglected and has been overshadowed by the advance of bacteriology. Many surgeons are of the opinion that this is to the disadvantage of the science and art of surgery, and consider that efforts should be made to stimulate the study of specimens obtained by operation or by autopsy. It is as a result of this feeling that the new 'Atlas of Pathological Anatomy' has originated." The first volume, compiled by Mr. E. K. Martin, has now been published. It is a fine production, containing 302 illustrations, 135 being coloured. The work is divided into five fasciculi dealing with tumours of bone, diseases of stomach, breast, kidney, gall-bladder and bile-ducts, and inflammation of bone. The specimens selected give a remarkably complete survey of the subject, and the accuracy of their reproduction is guaranteed by the names of the artists concerned—Mr. Maxwell and Mr. Sewell for the naked eye drawings and Mr. Ford for most of the microscopic slides. The paper and printing maintain a high standard.

In the preparation of a work of this kind two different methods may be used. The artist may be present either in the operating theatre or in an anteroom, where he may draw the specimen in its actual living condition. This, while ideal as regards colour and relations, has serious practical difficulties. For instance, Kast, Fraenkel, and Rumpel, adopting this procedure, needed 17 years to prepare their atlas for publication. The second much simpler method chosen in the volume under review is to confine the cases illustrated to museum specimens. This has the advantage that any reader sufficiently interested may visit the museum and inspect the actual material from which the illustration was drawn. The disadvantage is that however well a specimen may be preserved its colour is never that of the living tissue. This applies with particular force to some of the older cases here illustrated; for instance, no example of the common myeloma (osteoclastoma) of bone has any approximation to its true colour.

The editing is open to criticism in one or two respects, the most serious being the labelling of the illustrations. There is no heading at the top of the page, but the museum name and number, in rather small type, are tucked away in the lower left-hand corner; the description, on a different page, has a large heading, but the reference number is again hidden, this time in the middle on the right. This is especially irritating when one description applies to several plates of the same case. It could easily be remedied in future editions by printing the same heading at the top of each page dealing with the same material. The function of an index again is to enable any subject to be turned up rapidly. It is annoying to be constantly referred to some other title. These are, however, only matters of detail; in essentials the atlas is a most satisfactory production, and we shall look forward with pleasure to the next volume.

This work should help to raise the literature of British morbid anatomy to the position which it held in the best days of the New Sydenham Society.

A Short Practice of Midwifery.

Tenth edition. By HENRY JELLETT, B.A., M.D. Dub., F.R.C.P.I., Consulting Obstetrician to the Department of Health, New Zealand; Ex-Master of the Rotunda Hospital. London: J. and A. Churchill. 1930. Pp. 662. 18*s*.

THIS text-book of midwifery has now held its place as one of the most popular for over thirty years. The present edition appears to differ but little from its predecessors, the main change being found in the chapter on the treatment of eclampsia; this is particularly well done, and puts forward the present position clearly and impartially. Many obstetricians will be surprised to find that the author regards "prophylactic pubiotomy" as the ideal treatment of cases of contracted pelvis likely to cause trouble. In this chapter he emphasises the fact that in cases of disproportion forceps should be applied only for maternal or fœtal distress and not as a therapeutic measure for the treatment of the disproportion. This important principle of midwifery is rarely made so clear in the books.

Most authorities are now agreed on the difference between contraction ring distocia and retraction ring distocia. The ætiology of the two conditions is quite different, and treatment which is safe in the former would be most dangerous in the latter. Dr. Jellett does not seem clear about the best treatment to apply; he discusses operative measures which would, however, be highly dangerous if the lower uterine segment were thinned. The proof-reading has not been carried out too carefully. One serious error occurs in describing the method of delivery by forceps in persistent occipito-posterior positions. Here, the face is described as slipping from behind the perineum. Such an error, obvious though it may be, is serious in a text-book designed for students.

The book is easy to read and is well illustrated with clear and simple figures. It deserves to maintain its popularity for many years to come.

An Elementary Course in General Physiology.

By G. W. SCARTH, Professor of Botany; and F. E. LLOYD, Macdonald Professor of Botany, McGill University, Montreal. London: Chapman and Hall. 1930. Pp. 258. 13*s*. 6*d*.

"In contemplating vital processes we are at once confronted with phenomena which appear to be peculiar to life . . . . the increasing tendency of modern physiology is to analyse these into more fundamental, that is, physical and chemical, mechanism."

WITH these opening remarks the authors introduce their readers to a short course in general physiology, which has been planned with care. The book is divided into two parts, dealing respectively with the theoretical aspect, and instructions for the execution of practical exercises illustrative of the phenomena of life. The course is intended primarily for students, and in this respect it serves its purpose well, but the book could be profitably read by others who are desirous of familiarising themselves with the essential features of this branch of physiology. The various chapters deal with cell structure, surface tension, adsorption, diffusion, osmosis, H-ions, electric

potential, and colloids. The physical or chemical examination of all living tissues is open to the introduction of many fallacies, and these the authors are at pains to stress where necessary. The book is remarkably free from typographical errors, but in the first paragraph on page 221 the word "hypotonic" seems to be a misprint for "hypertonic." An appropriate bibliography is supplied at the end of each section. The authors respect the views of those who adhere to the vitalistic theory of life, and although it is their aim to support the mechanistic school of thought the reader is guided to an appreciation of the complex organisation of living matter, "so that in becoming a physical chemist he will not cease to be a biologist."

Dosage Tables for Roentgen Therapy.

By FRIEDRICH VOLTZ, Professor and Head of the Radiological Department, University Clinic for Women, Munich. Translated from the Second German Edition. London: Humphrey Milford, Oxford University Press. 1930. Pp. 120. 7*s.* 6*d.*

AFTER seven years a revision of this small and very useful volume was fully due, for X ray therapy has developed in many directions, especially on the technical side. Many new sections have been added to the work and the old ones have all been revised. The first edition has been for long the constant companion of all who work in therapeutic X ray departments. As the author explains, "it is not a 'prescription' book but is directed entirely towards the estimation of physical quantities. This estimation is necessary and will remain so, for whatever stress is laid upon biological factors it must always be remembered that the biological effect of X rays can only be ascertained quantitatively by means of physical constants." The book succeeds admirably in its purpose and has become an essential possession for all who use X ray therapy intelligently.

Sick Children: Diagnosis and Treatment.

By DONALD PATERSON, M.D., F.R.C.P., Physician to Out-patients, Great Ormond-street; Physician for Diseases of Children, Westminster Hospital. London: Cassell and Co., Ltd. 1930. Pp. 538. 16*s.*

Dr. Paterson has provided for the use of senior students and practitioners a volume of handy size dealing with certain aspects of pædiatrics. It is highly condensed, and theoretical considerations have been to a large extent eliminated. Each section contains a brief synopsis of the ætiology, but is almost entirely concerned with the diagnostic features and the treatment of the condition described. The illustrations are numerous and of high quality. The account of the feeding of infants and children is rather more detailed than other parts of the book, and contains useful diet tables. The chapter on the respiratory system is particularly lucid, and its value is enhanced by a series of admirable radiograms illustrating the progress of disease. The methods of treatment described are in nearly all cases those which have stood the test of time, and attention is paid throughout the book to the general management of the child and to psychological considerations.

Éléments de pharmacodynamie générale.

Par EDGARD ZUNZ, Professeur à l'Université de Bruxelles. Paris: Masson et Cie. 1930. Pp. 488. Fr. 75.

IT has been said that modern science consists mainly in amassing details, and that the special need of the moment is the formulation of definite laws from ascertained facts. Prof. Zunz's book is of particular value in that it discusses the general principles of pharmacodynamics, and attempts to determine the laws which govern the action of remedial agents. He could not have been expected to succeed completely in this aim, for pharmacology is based on the fundamental sciences of physics, chemistry, and physiology, in which, of course, finality has not been reached. But he is to be congratulated on the manner in which he has performed the difficult task of selecting his material, and on the judicious way in which he has handled it. He discusses the general principles concerned in the absorption, retention, and elimination of drugs, the ways in which they modify living tissues or are themselves modified, and the various factors which influence their action. Other chapters deal with tolerance, synergism, antagonism, the intricate subject of the relationship between chemical constitution and physiological action, and the methods of biological standardisation. Each chapter is followed by an excellent bibliography drawn from a great variety of journals, which should prove of considerable assistance to those interested in the literature of the subject.

Prof. Zunz's work should stimulate further study of this important branch of medical science.

The Psychology of Clothes.

By J. C. FLÜGEL, B.A., D.Sc. London: Hogarth Press and Institute of Psycho-Analysis. 1930. With 32 illustrations. Pp. 256. 25*s.*

THIS book is the latest addition to the International Psycho-Analytical Library, a series of volumes issued under the general editorship of Dr. Ernest Jones, to which Dr. Flügel has already contributed a study of the influence of the family on the mental development of the individual, the evidence being derived through psycho-analytical methods. Of the present work the thesis is that an investigation of human dress from the earliest down to modern days will display the psychological relations of clothing. The inspiring character in "Sartor Resartus" expressed the view thus—"neither in tailoring nor in legislating does man proceed by mere accident, but the hand is ever guided on by mysterious operations of the mind."

The parts played by modesty, love of ornament, and need for protection are set out by Dr. Flügel in a clear and amusing manner, and there is a particularly informing chapter on "sex differences." Here the reflection that the more uniform and less decorative costume of modern women in the daytime is due to the active part now played by them in social life is an obvious one, but the remarks on the masculine renunciation of gay and elaborate clothes and its effect on male psychology are shrewd. Of less medical interest are the sections on the types of dress, the forces of fashion, and the evolution of garments, while the chapter on the future of dress conveys in a tentative manner the view that the wearing of clothes is but an episode in human history—a prolonged episode as the author's studies show—and that nudity will become the rule.

The book is timely as well as good. The part played by the application of psychological teaching to ætiology and therapeutics becomes increasingly apparent, and knowledge such as is deftly conveyed by Dr. Flügel, which not long ago would have been considered by medical men as interesting because curious, is seen to-day to have many practical applications.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 22, 1930.

ACUTE APPENDICITIS.

BOTH in diagnosis and treatment abdominal surgery has made great advances during the last 20 years but, judging by results, acute appendicitis has not been taking its proper share in this improvement. While estimates vary, there is general agreement, both here and in America, that the mortality is unnecessarily high. E. R. FLINT gives it as 5·7 per cent. in a group of 1080 cases at Leeds General Infirmary; MCNEILL LOVE'S figures show a death-rate of 6·2 per cent. among 3123 cases treated in two London teaching hospitals; JEFF MILLER [1] finds 9·9 per cent. of fatal cases among 2415 admitted to the two largest institutions in New Orleans. GREY TURNER, on the other hand, is able to report a mortality of 3·5 per cent. among 2252 cases of his own, and there can be little doubt that even this proportion could be much reduced if the knowledge in our possession were generally applied. The organisation and provision for dealing with surgical emergency in municipal and urban districts is improving; hospital accommodation is more adequate; but there is still need of a compelling sense of the urgency of acute appendicitis. The truth has been a little fogged by expert discussions on expectant treatment but, in fact, as Mr. BARRINGTON-WARD says on p. 1126 of our present issue, "the whole surgical opinion of the world is agreed on one point. If a case of appendicitis is seen within 24 hours of the onset of the attack, operation should be undertaken." There are, indeed, no two opinions on the treatment of acute appendicitis; authorities differ only on the treatment of the *peritonitis* which may result from failure to remove the appendix in time. The best moment for operation has then passed and it is these cases that account for the high mortality. Therefore, no effort should be spared to secure that every case is seen by a surgeon and submitted to operation within 24 hours of the onset.

"Earlier diagnosis" is a cry one hears on every hand in surgery and medicine, but never with better cause than in acute appendicitis. Every case which goes on to perforation should be regarded as a failure, and if there is a failure of this kind the responsibility presumably lies with one or more of those concerned—the patient, the practitioner, and the surgeon. Clearly the patient often has himself to blame. He seldom knows, for instance, that the appendicular pain is usually referred to the *centre* of the abdomen above the umbilicus; if he did, he would go to his doctor in this, the stage of obstruction of the appendix. But instead the disease proceeds unobserved to involvement of the visceral peritoneum, made manifest by pain in the right iliac fossa. Then the patient himself—unless unlucky enough to be a child—will probably suspect the possibility of appendicitis, and seek medical advice. But already much damage may have been done. Self-medication is becoming increasingly common, and for general abdominal pain the parent, the chemist, the school matron, or the nurse still recommend "a good dose of castor oil." The danger of this dose must be more widely appreciated. Lord MOYNIHAN is reported to have said that he never saw a ruptured appendix in which purgation was not only an impressive antecedent but a definite cause. We must somehow teach, until it is general knowledge, that the treatment of abdominal pain is to put the patient to bed and send for a doctor. Only the doctor can decide when, if at all, a purgative is needed and can be safely given.

When the practitioner diagnoses appendicitis, what is he to do? If there is an area of localised rigidity in the right iliac fossa the appendix is probably turgid, obstructed, inflamed, and on the point of perforation. The case is an emergency; there is one line of treatment only; no time may be lost before the appendix is removed. The choice of nursing home or hospital, the giving of enemata, the examination of the blood—these must not delay getting the patient to the theatre, for no stage in the disease is as urgent as this. If peritonitis or an abscess is already present when the case is first seen, preparation for operation should proceed, for the decision to delay operation should rest with the surgeon, and expectancy is only permissible under his immediate supervision with the theatre ready at hand. Even if the practitioner thinks that delay offers the best chance he will be well advised to call a surgeon as soon as possible, for only by repeated examination can the latter determine whether peritonitis is subsiding or extending. His decision may be far from easy, for even "simple" cases may require the best of surgical judgment and technique. It is now generally agreed that a limited approach is undesirable where there is doubt of the diagnosis, but in the presence of peritonitis there is much to be said for a lateral incision, since it causes less disturbance of limiting adhesions, and therefore less soiling of the general peritoneal cavity. The fixity of the appendix adds to the difficulty of its removal; a minimum of manipulation of the inflamed ileum is desirable; and on this account the lateral oblique incision of MORISON is preferred by many, and allows of convenient drainage of the appendix bed and usually of the pelvis. The essentials of the after-treatment are well understood and generally practised—namely, rest and the maintenance of the fluid supply by the rectum. Purgatives must be avoided until the toxæmia and ileus are passed and the enthusiasm of the efficient sister, to whom the giving of aperients is often deputed, must accordingly be curbed. Intestinal paralysis, with its silent distension and slow poison after the early use of purgatives is only too ready to return.

[1] Jour. Coll. Surg. Austral, July, 1930, p. 40.

DENTAL CARIES AND DIET.

THE causes of dental decay in children are still the subject of lively controversy. One school holds the view that caries is produced by lack of oral cleanliness, and that the best diet for its prevention is the one which avoids bacterial multiplication in the mouth; the other school maintains that the chief predisposing cause of caries is the faulty nutrition of the teeth, due to the imperfect calcifying properties of the diet. This latter point of view was first put forward by M. MELLANBY many years ago, and she has since supported it by a mass of experimental evidence and clinical observation, including a demonstration that caries in children can be arrested by supplying those dietetic factors which promote good calcification of the bones and teeth. The dental officer and physician in charge of the department of pædiatrics in the University of Iowa College of Medicine reported in 1928 [1] that they had observed a number of instances of arrested caries in children, and on examining the records of the cases had found that without exception these children were diabetic patients who had been under treatment for six months or more. The disease itself was not responsible for the arrest of caries, for in many of the children during the early periods of observation active spread of caries was obviously taking place. The diets given to these patients consisted largely of milk, cream, butter, eggs, meat, cod-liver oil, bulky vegetables, and fruits. The predominating features of these diets are their richness in fat-soluble vitamins and mineral salts, and their poverty in carbohydrate, especially carbohydrate in the form of cereal. It was noted that with these diets caries was arrested whether the usual routine of oral hygiene was scrupulously carried out or entirely neglected. Observations have since been made by the same workers [2] on the arrest of caries in children not suffering from diabetes. It was very soon found that the diabetic diets were just as efficient in producing arrest of caries in other children; unless, however, continuous supervision was exercised over the food actually eaten by these children, active caries would begin again after it had been arrested. It is mentioned that the children were allowed sweets after their meals, but not at other times. Considerable variation in the distribution of calories between fat and carbohydrate was found to be compatible with arrest of caries. Provided that cod-liver oil, a large quantity of milk, and a certain amount of fruit and fresh vegetables were given, arrest of caries was observed both when large amounts of fat and when large amounts of carbohydrates in the form of sugars or other simple carbohydrates were included in the diet. Large unfilled cavities in which acid-producing bacteria could collect were purposely left in some of the children receiving the protective diet, and in no case did the caries progress as the result. It was known that some of the children in whom arrest of caries was determined did not use a toothbrush. In some cases the parents maintained before treatment was begun that their children were already receiving substantially the same diet that was now being recommended for them, and it was only by insisting that definite fixed quantities of the protective foods should be regularly taken by the children that the desired results were obtained. No details of individual cases are reported in these papers, but the conclusions are in line with the clinical results previously obtained by Mrs. MELLANBY. In each case the dietetic factors which produced arrest of caries were essentially a liberal supply of foods rich in fat-soluble vitamins and a minimal supply of cereal. Both are in favour of the view that the cause of dental caries is rather a general metabolic disturbance affecting the nutrition of the teeth than a local process arising from faulty oral hygiene.

NEW METHYLATED SPIRITS REGULATIONS.

SUBJECT to a protest made below in a matter to which the Earl of Donoughmore's Committee on the powers of departments is doubtless giving attention, we welcome the fact that the new Methylated Spirits Regulations (which will come into force on Jan. 1st) are accompanied by valuable explanatory notices. Part X. of the new Regulations deals with industrial methylated spirits for medical and other purposes. Article 50 in Part X. concerns wholesale chemists and dispensing chemists and their authority to receive industrial methylated spirits for sale. Article 51 concerns dispensing chemists and their authority to receive such spirits for dispensing purposes. Article 53 deals with medical practitioners, dentists, veterinary surgeons, hospitals, and nursing homes. The Commissioners of Customs and Excise circulate an explanatory notice in respect of each of these three Articles. Industrial methylated spirits are defined as consisting of 95 parts of ethyl alcohol denatured with 5 parts of wood naphtha. A medical practitioner or other person or body within Article 53 may obtain such spirits in quantities not exceeding half a gallon at a time from any authorised wholesale chemist or dispensing chemist merely on a written order signed by a medical practitioner, dentist, or veterinary surgeon. Hospitals and nursing homes, suggests the official notice, should arrange for a doctor to whom they are known to sign orders for them. Apart from this provision, any medical practitioner, or other person or body within Article 53 may, on application to the nearest officer of Customs and Excise, obtain authority to receive industrial methylated spirits. Such officers presumably are not to be found by merely shaking the branches of the nearest tree, and it would have been helpful if the notice had contained hints for their discovery. Armed with the necessary authority the practitioner or other person forwards a requisition in an official form from a book which the officer will supply. On the requisition a methylator may supply not less than five gallons at a time, or an authorised wholesale or dispensing chemist may

sell quantities not less than four gallons at a time. Under whichever of these provisions the spirits are obtained, they must not be used or disposed of for any other purpose than (*a*) making up articles to be dispensed for medical, surgical, dental, or veterinary purposes; or (*b*) use or dispensing (without admixture or diluted with water) for some medical, surgical, dental, veterinary, or scientific purpose.

Not all these provisions seem to be patent upon the face of the Statutes or the new Regulations made thereunder. This brings us to the protest which we desire to place on record. Article 53 refers vaguely to conditions which the Commissioners of Customs and Excise may prescribe. It appears from the accompanying notice that the Commissioners have in fact prescribed at least two important conditions. One is that no greater quantity than one pint of industrial methylated spirits is to be dispensed at one time to or for the use of one person, either alone or as an ingredient in any article. The other condition is that every bottle dispensed to a patient must be labelled "for external use only" or "not to be taken" or otherwise to the same effect. We can see no conceivable reason why these "conditions" could not have been inserted in the Regulations themselves. It is bad enough that Acts of Parliament should be meaningless and unworkable without reference to "Statutory Rules and Orders" made under the Acts. It is far worse when even these Rules and Orders are supplemented with further subordinate legislation. We seem to have heard of the legal maxim *delegatus non potest delegare*. If the maxim has any force, is a department entitled, when a power of legislation is delegated to it, to delegate to itself indefinitely some further power of legislation? Even if such conduct is legally correct, it is slovenly and inconvenient. Acts and Statutory Rules and Orders should be complete in themselves. The medical practitioner who painfully studies and obeys them should be immune from further prospective penalties. But, as the law of industrial methylated spirits is likely to stand next year, a doctor may find himself in trouble for non-compliance with something "prescribed" with less than the proper formality and publicity. Even the restrictions imposed by Regulations under the Dangerous Drugs Acts never went so far as this.

ANNOTATIONS

MEDICINE AND THE STATE.

THE Public Health Congress was opened at the Agricultural Hall on Monday last by the Minister of Health. At this time, when schemes of State and universal medical service are being discussed on all sides, it is natural that the first subject prescribed for discussion should have been "Medicine and the State." Sir Arthur Newsholme, in a paper read at the opening session, laid down as governing principles the following nine postulates: "Every member of the community should have, so far as essentials are concerned, equal provision for the treatment of illness. Complete medical service must be available gratuitously for all who cannot pay. The patient's welfare forms the primary and predominant consideration in all planning for a 'general medical service.' A consultant service and all necessary specialist and ancillary forms of diagnosis and treatment should be available for the individual patient, normally through the agency of the family doctor. Treatment should be educative. The causes and conditions leading to illness should be sought out and, to the full extent practicable, preventive advice should be given and preventive action taken. Neither medical practitioner nor medical officer of health should allow his attention to be monopolised by treatment, thus diverting study and action from preventive measures. The individual doctor can only fulfil the immense possibilities of good implied in his relationship to his patient when he is imbued with a living appreciation of the profoundly ethical importance of his work and his teaching. For medical treatment the family, not the patient, should be the unit. It is in the interest of the family, ceteris paribus, that one doctor should be able to examine and advise every member of the family. It is dishonest to assume and continue responsibility for the treatment of a patient unless one has sought to obtain accurate knowledge, determined by detailed examination of his physiological systems, of the patient's fundamental conditions of health."

In commenting on these points Sir Arthur Newsholme acknowledged the debt owed by the public health service to lay experts and to the devoted work in the past of private charity, in general practice, in poor-law provision, and in hospital work. Mentioning the "abuse" of the hospital by the panel patient, he took occasion to upbraid the abuse of the patient by the hospital—the waste of time and perfunctory work involved in the present system of seeing patients without appointment. The public health authorities, he said, would be happy to hand to the family doctor their work for infants, children, and the tuberculous as soon as the country developed a general practitioner system which would ensure the regular and reliable overhaul of every child and patient. The excessive expenditure on social services could not be met by stopping any medical service; it could be met by coördination and curb on overlapping and extravagance. Often ad hoc buildings and staffs were provided for each service, where a single health centre would be more efficient as well as more economical. The day of single-handed medical practice is past, Sir Arthur declared, but expert assistance must only be available in collaboration with the ordinary medical attendant, who must learn to be a medical officer of health in the range of his own practice, and must not lose his essential position as family adviser. The increase in specialised knowledge which makes it so hard for one man to be an adequate medical adviser could be largely met by grouping practitioners in an area, so that the opinion of each or all was available for any patient. In conclusion, Sir Arthur touched on the vexed problems of over-prescribing and certification, suggesting as remedies that the doctor should resolve never to give a prescription that he would not give to his own family, or that was only a placebo to cover inadequate understanding of the patient's condition; that the patient should pay a part of the cost of drugs; and that the sickness insurance societies should be regionalised and placed

in some respect under county and county borough administration so that excessive sickness could be analysed and investigated.

OCULAR NEUROSES AND SO-CALLED EYE-STRAIN.

How are we to treat a patient who complains of persistent pain and discomfort in the eyes when the most painstaking examination can find no error of refraction, except such as has already been corrected by appropriate glasses, no defect of muscle balance that could possibly cause the symptoms complained of, no undue demands on the accommodation, and no abnormality of the conjunctiva, cornea, fundus, lens, or other structures of the eye, or defect in their functional activity? In these cases there is a temptation to tell the patient that he is suffering from "eye-strain" and to prescribe rest from near work, when there is no certainty that the diagnosis is the correct one or the treatment likely to be effective. Or it may be that discovering an error of a quarter of a diopter, or even of one-eighth, in the astigmatic correction that the patient is wearing, or an error of 5° in the axis of a weak oblique cylinder, we are inclined to attribute everything to that. It may be that there are patients to whom such diagnoses are applicable, but they are certainly very rare. Dr. George S. Derby, of Boston, speaking at the eighty-first annual session of the American Medical Association last June,[1] expressed the opinion that in his country the ophthalmologists produced more neuroses than they cured. "Eye-strain," he says, "is a terrible and serious bugbear to the public; would that the word had never been coined." And again, "It is far more dangerous to tell a patient to rest a healthy pair of eyes than to use them. Many a sensitive patient has been made hypersensitive by the prescription of rest and dark glasses." Without questioning the importance of correct refraction he implies that the injury inflicted by incorrect glasses is far less than that due to the unnecessary prescription of glasses at all for patients who are inclined to be neurotic. As an example, he cites the case of a healthy man of 48 who, complaining of some discomfort of the eyes with normal vision but a hypermetropia of plus 1·0 D., had had spectacles of plus 1·0 prescribed for distance. He had further been advised to give up smoking, card-playing, the movies, driving a car, and reading, and to lie down every afternoon to rest his eyes. All this advice he had followed without the slightest benefit, and he still suffered from aching eyes. On returning to a normal life and giving up his distance glasses, so that his attention was taken away from his supposed eye troubles, he was cured. Dr. Derby's treatment of these cases is to discuss with them their habits of life and suggest improvements. Rarely, he says, is it necessary to call in a trained psychologist. In 95 per cent. of these cases what is needed, he finds, is a willingness to spend some time in studying the case, and sound common sense. In the discussion that followed Dr. Derby's paper there was general agreement with his point of view, though some speakers were inclined to criticise him for laying too little stress on the necessity for an absolutely accurate refraction. This sort of criticism would also probably be made by many in this country who believe, with Mr. Ernest Clarke, that the difference of a quarter, or even an eighth of a diopter, in the strength of a cylinder may make all the difference between comfort and discomfort for the patient. It probably depends upon the patient, and no rule can be laid down which shall be applicable to everyone. In the case of purely spherical corrections of a minimal degree, however, there can be no question that it is a mistake to insist on the wearing of glasses for distance in the hope that it will cure symptoms, unless the prescriber relies on the power of suggestion rather than on that of common sense.

FUNCTIONAL ALBUMINURIA IN CHILDREN.

THE occurrence of albuminuria in children and adolescents in a functional, cyclical, or orthostatic form has attracted attention for many years. Extensive investigation has always been difficult, because there are obstacles in the way of collecting numerous specimens of urine from groups of healthy young people, and apart from H. H. Bashford's studies at the General Post Office,[1] most of the information published in this country has been derived from insurance work and examination of recruits for the Army. The results of a large inquiry are now recorded from Kharkov in the Ukraine by F. Levitus and W. Rabinowitsch,[2] who have observed the incidence of functional albuminuria in a group of 1421 healthy school-children ranging from 8 to 14 years of age. From a single analysis 197 children were found to have abnormal urine, a percentage of 13·8. Up to the age-limit of 14 the occurrence of albuminuria increased with age, and a sex difference, noted by other authors, was shown by the fact that girls in the younger age-groups, between 8 and 12, had a higher percentage of albuminuria than boys. Some writers have maintained that the presence of acetone bodies in the urine in addition to albumin is a feature of these functional cases, but Levitus and Rabinowitsch found no such association in two-thirds of the cases. The amount of albumin varied from a trace to 3·3 parts per 1000. The presence of renal epithelium besides albumin was noted in 69 per cent. of cases, and casts as well in 12·7 per cent. Thus the presence of these bodies did not by any means negative the diagnosis of functional albuminuria. It was realised that a single specimen of urine is useless for exact diagnosis of functional albuminuria, so two groups of 100 children were selected in one of which a single examination had shown normal, and the other abnormal, urine. In both groups four specimens of urine were collected during the day. By making the children micturate once during the night, two to three hours after they had gone to bed, it was arranged that the morning specimen should contain none of the previous day's urine. Three other specimens were obtained, at midday, afternoon (3 to 4 P.M.), and evening (8 to 9 P.M.). Although the morning specimens contained albumin much less often than those obtained later in the day, they were by no means always free from it, and there seemed to be no definite optimum time of day for obtaining either positive or negative specimens. Thirteen cases of albuminuria were found among the 100 children who had shown normal urine on a single examination, so that the true percentage incidence in school-children was raised from 13·8 to 26·8. It has often been maintained that children with functional albuminuria complain of various vague symptoms such as poor appetite, headache, and dizziness, but comparing two groups of albumin-free and albuminuric patients, Levitus and Rabinowitsch could find neither quantitative nor qualitative differences in such subjective symptoms. No difference could be found, either, in the previous occurrence of the

[1] THE LANCET, 1926, ii., 1305.
[2] Jahrb. f. Kinderh., Oct. 1930, p. 188.

specific fevers in the two groups, nor was there any obvious difference in the habitus of the children who had albuminuria as compared with the other children. Blood counts, blood-pressure readings, and tuberculin tests all gave the same result—namely, that albuminuria as a "functional" condition does not appear in any special type of child. There is therefore, they hold, no definite clinical picture apart from the urinary findings. The occurrence of alternating positive and negative phases is looked upon by these investigators as the essential feature for diagnosis, and in five cases in their series where albuminuria was constant the diagnosis of chronic nephritis was considered to be the correct one.

THE HAUSA AND THEIR DIET.

THE northern provinces of Nigeria are inhabited largely by a negroid mixture of races spoken of as the Hausa, and by a semitic race known as the Fulani, which has given up its original nomadic life and settled in towns. Dr. W. E. McCulloch[1] has conducted an inquiry into the dietetic habits of these natives and has attempted to correlate certain specific food deficiencies which his investigations have revealed with the very unsatisfactory state of health existing in this part of the world. The inhabitants are by no means savages, but general ill-health is widespread among them, and their infant mortality-rate is appalling. Their physique is not strikingly different from that of European races, but their weight is less than that of individual Europeans of the same height, and they reach their maximum height at an earlier age than white races of mankind. Their resistance to infections is notoriously low, as it appears to be throughout the negroid races of Africa. Epidemics of relapsing fever and small-pox sweep through the country with devastating results, and bronchitis, pneumonia, and tuberculosis steadily claim large numbers of victims. Gastro-intestinal disturbances are common, and may furnish half the cases that attend the native hospitals. The teeth of the women are usually well preserved, possibly owing to their habit of chewing the flowers of the tobacco plant which stain the teeth and appear at the same time to protect them from caries. The teeth of the children and of the men are rarely good, and cannot be compared with the remarkably good teeth of the West Indian negro who habitually chews sugar-cane. The birth-rate is low, largely on account of the reduced fertility of the male, who indulges in polygamy; abortions are very frequent, although syphilis does not appear to be particularly widespread. In one of the chief towns the infant mortality-rate for 1927 was 412 per 1000. Specific food deficiency diseases are not uncommonly met with. Beri-beri and scurvy occur during times of scarcity, goitre is fairly prevalent both among the inhabitants and among their cattle, and xerophthalmia is met with in young children. Rickets appears to be a rare disease; chronic anæmias are common.

The staple foods of the natives are millet seed, Guinea corn, adulterated sour milk, and soup composed of green leaves. Ground nut oil and meat are used sparingly by the masses and in relatively large quantities by the more wealthy families. Condiments, spices, and sweets are widely consumed. The native "salt" contains little or no chlorine. The glaring fault of the dietaries is that they are apt to consist almost entirely of cereal products. Milk is purchased in fairly large quantities, but in view of the fact that it is habitually adulterated with more than half its bulk of water before it is sold, the true consumption is not large, which means that the population suffers from a deficiency of calcium and of protein of good biological value. Fat-soluble vitamins must be markedly deficient, and though the lack of vitamin D in the food is to a great extent made good by abundant sunshine, the shortage of vitamin A is probably related to the susceptibility of the population to infections. Vitamins B and C are present in insufficient quantities, so that with any restriction of diet definite symptoms of the corresponding deficiencies may become manifest with great rapidity.

The recommendations made by the author for improving the nutritional status of these peoples are based on strictly practical and economic lines. In the first instance, every encouragement should be given to increase the quantity and improve the quality of the milk consumed by the masses. This could be brought about by exempting milk-bearing cattle from the cattle tax on condition that they were kept for supplying milk to urban populations, and by making the adulteration of milk an offence punishable only by imprisonment and not by fines. The deficiency of mineral salts and vitamins could be partly corrected by planting in the neighbourhood of the towns large reserves of trees with edible leaves, of which a considerable variety are known. The sweet potato is a valuable crop, not merely for the sake of its tubers but on account of the richness in calcium of its green leaves, and its cultivation should be strongly encouraged. These comparatively simple suggestions should help very materially to correct the very imperfect diets in vogue at present, and the obvious benefits to be expected from their wide adoption would make it easier to introduce in the future still further dietary improvements.

[1] An Inquiry into the Dietaries of the Hausas and Town Fulani of Northern Nigeria, with some Observations of the Effects on the National Health, with Recommendations arising therefrom. By W. E. McCulloch, M.D. West African Medical Journal, 1929–30, vol. iii.

ANTITOXIN TREATMENT OF DIPHTHERITIC PARALYSIS.

THE employment of antitoxin in diphtheritic paralysis, which has been advocated by several clinicians on the Continent, notably by Comby in France and Heubner and Jochmann in Germany, has received little support in this country, in view of the natural tendency of this condition to spontaneous recovery and the failure of the treatment in experimental diphtheritic paralysis. Commenting on a case recorded by the late Dr. G. S. Middleton in these columns many years ago, Dr. J. D. Rolleston[1] suggested that the success attributed to this treatment was due less to a specific than a psychotherapeutic action. Last month, however, Prof. U. Friedemann and Dr. A. Elkeles,[2] who appear to be rather in favour of the method as the result of their clinical experience, record some experiments on rabbits which they think give some evidence supporting the serum treatment of diphtheritic paralysis. They found in the first place that both in the normal rabbit and in the human subject suffering from diphtheria, antitoxin could not penetrate to the cerebral circulation, so that it might be supposed that diphtheritic paralysis could not be affected by serum treatment. This supposition, however, was met by the fact that intracerebral diphtheritic intoxication in the rabbit could be cured by large doses of antitoxin injected intravenously,

[1] THE LANCET, 1908, ii., 261.
[2] Deut. med. Woch., Oct. 10th, p. 1725.

the apparent discrepancy being explained by the theory that cerebral diphtheritic intoxication renders the cerebral circulation accessible to antitoxin. The application of these experiments to diphtheritic paralysis in man is that in this condition diphtheria toxin is firmly attached to the central nervous system, and therefore the possibility of the cerebral circulation being accessible to antitoxin must be considered. The experiments, however, indicate that only very large doses of antitoxin offered any prospect of success. Moreover, the writers admit that their experiments deal only with prophylaxis, whereas in clinical diphtheritic paralysis the question is one of treatment. It may be mentioned in this connexion that Rosenau and Anderson,[3] to whose experimental work on guinea-pigs the German writers do not allude, found that a very small quantity of antitoxin, given 24 hours before or at the time of infection with diphtheria toxin, prevented the development of paralysis, and that antitoxin given 24 hours after infection modified the paralysis. On the other hand, they found that antitoxin administered during the various stages of the paralysis had no power to save life or ameliorate the symptoms; neither had antitoxin any influence in preventing paralysis if injected shortly before the paralysis began.

AN AMERICAN PSYCHOPATHIC HOSPITAL.

VISITORS returned from the United States have a lot to say about the enlightened endowments and systematic psychological and psychiatric education which they find in that country, while those who remain at home are irritated into believing that these advantages have been greatly exaggerated. Since it is always hard to draw the line in the right place between disparagement of one's own country and other people's it is interesting to compare the report of an institution such as the Boston Psychopathic Hospital with our British mental hospital reports.

The medical director of the Boston Hospital points out that its three main functions are so closely related that any effect on the one must react on the others. These functions are: caring for the mentally and nervously disordered, carrying on continuous research into the causation and treatment of this special form of illness, and providing a training centre for a great variety of workers in this special field—from medical graduates to laboratory assistants. "The fundamental test of the hospital," he says, "is the care and treatment of the individual patient, but satisfactory treatment of the individual sick person is only possible when there is, in addition to the goodwill, sympathy, and conscience of the individual physician, a keen interest in the special medical problems presented by the individual case; not only an interest in recognising what is familiar in the disorder, but curiosity as to the significance of what is unfamiliar and eagerness in the systematic investigation of what is still obscure." He goes on to show that this attitude must necessarily imply vital coöperation with the pathologist, the nurse, the occupational therapist, the psychologist, and the social worker as well as with the patient himself. He summarises a number of cases to show the kind of work that is done and the way in which the artificial barriers which separate so-called mental and other ailments are being steadily broken down. The cases quoted raise problems of the widest possible nature: problems of internal medicine, of the varied endowment of human nature and its varied vulnerability, of the moulding influences in individual life, of the occupational field and conditions of work, of different standards of success and failure, of the organisation of the community, and of the material and cultural satisfaction available for all sorts and conditions of men.

Special reports come from the out-patient department, where 1135 patients were seen during the year; from the chief medical officer, with special reference to X rays and therapeutics, including dental care; from the biochemical laboratory, which emphasises again the impossibility of divorcing psychiatry and internal medicine; from the psychological laboratory, which has a large research output; from the neuropathological laboratory; from the department of therapeutic research; from the syphilis service, from the social service department; from the school of nursing; and from the department of occupational therapy. All these, with ample informative tables, are included in a pamphlet of 50 pages no larger than most of our own mental hospital reports. The result makes us feel that even if psychotherapists in this country have nothing to learn from abroad in their methods or application, they might yet contrive to report their endeavours and successes with more of that infectious enthusiasm which makes for progress.

TUBERCLE IN CHILDREN: A LANCASHIRE STUDY.

MOST authorities are agreed that the diagnosis of pulmonary tuberculosis among children under the age of 15 years is beset with difficulty, a fact which may account for the widely differing statistics of its prevalence. Dr. G. Lissant Cox, in his report for the year 1929 on the prevention and treatment of tuberculosis in the administrative county of Lancaster, points out that the proportion of children (per 1000 of the child population) accepted by the county tuberculosis officers as suffering from pulmonary tuberculosis is very low as compared with that in other counties. In order to test whether many cases of the disease were being missed among the children referred as suspicious cases by practitioners and school medical officers, an investigation was started to ascertain whether any considerable number of these rejected cases were returning later in life with definite disease. This investigation was carried out by listing the consecutive case-sheets of 1545 young adults between the ages of 15 and 25 diagnosed by the tuberculosis officers as suffering from tuberculosis (all forms) during the past three years. It was found that of 1084 young adults coming on the dispensary registers as new pulmonary cases, only 0·64 per cent. had been previously rejected in childhood by the tuberculosis officers. Moreover, of 17,000 children, excluding contacts, referred to the tuberculosis officers between 1928 and 1914, when the Lancashire Dispensary scheme began, some 59 per cent. were diagnosed as non-tuberculous. That this diagnosis was fully justified is evident by the fact that these children did not return in the young adult age to the dispensary as definite cases of pulmonary tuberculosis. These conclusions bear out the findings of Dr. W. Burton Wood, who showed that the children of the dispensaries and sanatoriums are not the children who develop consumption in adolescence, and that a history of "pre-tuberculous" childhood is practically unknown among adolescent consumptives. The close connexion between the number of children taken on the dispensary registers by the tuberculosis officers in a given area and the amount of sanatorium accommodation provided for the treatment of the children has not escaped the notice of Dr. Cox, who draws attention to the fact

[3] U.S. Public Health Service, Bull. No. 38, 1907.

that the very conservative diagnosis in his area of pulmonary tuberculosis in children has meant a small demand on sanatorium beds, with a consequent saving of public money.

RUPTURE OF THE HEART.

A SERIES of 46 cases of spontaneous cardiac rupture has been studied by E. H. Beresford and C. J. C. Earl,[1] who show that it is chiefly a senile catastrophe. In 9 of the 14 cases which were more fully investigated the patient died suddenly, one being found dead in bed. Only one showed any of the classical symptoms of cardiac infarction, yet in all the 14 cases examined histologically the rupture had occurred through the site of a recent infarction. In discussing the actual cause of the rupture, Beresford and Earl stress the frequency with which this lesion is found in hearts showing gross fatty infiltration of the heart wall. From observations of incompletely ruptured hearts they conclude that the muscular contraction of the rest of the heart, the fatty infiltration, and capillary hæmorrhage into the myocardium (as the result of the infarction) are the main adjuvants to the infarction in the mechanism of spontaneous cardiac rupture.

MOTHER AND FŒTUS.

THE substances which are requisite and necessary for growth and development pass readily through the placenta from mother to fœtus. So, in human beings, do more complicated and casual substances, such as antibodies. Much less is known about the possibilities of transference from fœtus to mother, and it is obviously a matter on which exact observation is difficult and experiment hazardous. Suggestions have been made by Dienst and others that the toxæmias of pregnancy, in particular eclampsia, are due to incompatibility between mother and fœtus and the absorption by the mother of something which produces an undesirable reaction. There is but little direct evidence in favour of this view and it is contradictory. Special interest, therefore, attaches to evidence lately brought forward by Dr. Kathleen Edgecombe [2] that antigens may pass from fœtus to mother and rouse an antibody response in the latter. Working in Liverpool with the late Prof. E. E. Glynn she followed the agglutination titres for red cells of a number of pregnant women and finally tested the blood group of the baby, which, as is well known, is often not fully established at birth. With a fœtus with no defined blood group at birth, the titre of the mother's serum showed no change during pregnancy; if the fœtus was of the same group there was some increase in agglutinins, while with a fœtus of a different group there was a large rise. In each case which was tested any increase found during pregnancy passed off and disappeared after childbirth. The natural interpretation of these results is that protein substances capable of acting as antigens may traverse the placenta from fœtus to mother. There is nothing inherently improbable in this, but Dr. Edgecombe is, we believe, the first to bring forward anything like definite evidence that such a transference actually occurs under normal conditions. There are other points in her work which are not so easy to understand. Why, for example, should the titre of the mother's serum rise at all with a fœtus of the same group? More curious still is the fact that the mother's cells become more agglutinable if the agglutinating titre of her serum increases. There is, evidently, room for a good deal of further work.

[1] Beresford, E. H., and Earl, C. J. C.: Quart. Jour. Med., October, 1930, p. 55.

INFANT FEEDING BY APPETITE.

H. P. Wright and A. K. Geddes[1] point out that the number of different methods of infant feeding which have been used successfully shows that the normal infant will thrive on diets of widely different composition. In Berlin, for instance, the children of protein milk and butterflour enthusiasts flourish side by side. One of the difficulties of artificial feeding is the frequent readjustment of the amount of mixture required, and to overcome this Wright and Geddes use the infant's appetite as regulator. Their exact technique is as follows. All babies are given five four-hourly feeds in the 24 hours and are fed for 20 minutes by the clock. Each baby under three months of age is held while being fed. An ordinary anticolic nipple is used with a fairly large hole so that the child can get as much as it wants in the 24 hours. The formula given is lactic acid whole milk 20 oz., plus 50 per cent. corn syrup 2 oz. When a baby takes 32 oz. of this mixture in the day cereals are offered twice daily, vegetable broth once, and the number of feeds is reduced to four, and when the child is taking two plates of cereal the feeds are reduced to three. Boiled water is offered to all infants between feeds, and cod-liver oil and orange juice are also given daily. It is interesting to note that on this routine an extraordinary variation in intake was found. Cereal feeding was often begun at four months and by six the feeds had been reduced to four in the day. Of 20 children fed in this manner all did well except two, who both suffered from organic disease.

COTTON DUST AND ASTHMA.

A REPORT,[2] issued by the Industrial Health Research Board, on sickness among operatives in Lancashire cotton mills is, as its author states, somewhat elaborate; the intricate analysis of large numbers of statistical tables makes it rather difficult to follow. To temper the wind of mathematics the reader is, however, provided with a useful summary according to the admirable custom now adopted by the Board. Interest lies in the story behind the inquiry as well as in the results, which have been extracted with skill and not without difficulty. As long ago as 1908 a special disease—cotton strippers' asthma—was described by Prof. E. L. Collis, and was attributed by him to dust extracted from raw cotton while it is being prepared for spinning processes. Modern methods (vacuum exhaust appliances) have since been introduced to carry away the dust; but the operatives, while appreciating the great consequent improvement, hold that troublesome dust still remains. This view is not accepted by the employers. Hence the present inquiry to ascertain by reference to sickness records how matters stand. The records used are for the five years 1923 to 1927; and those familiar with the difficulties associated with collecting and then analysing such records must admire the masterly way in which Dr. A. Bradford Hill has tackled the problem. He found that from ages 30 to 59 the operatives concerned suffered over three times as much from sickness due to respiratory causes as did their immediate fellows not employed in the same room. This sickness incidence is due to more men making claims and to more men making

[1] Canad. Med. Assoc. Jour., October, 1930, p. 537.

[2] Sickness amongst Operatives in Lancashire Cotton Spinning Mills. By A. B. Hill. Industrial Health Research Board, Rep. No. 59. 1930. London: H.M. Stationery Office. Pp. 81. 1s. 6d.

repeated claims, rather than to abnormally long periods of respiratory illnesses. Other forms of sickness were not in excess. Men of the ages mentioned must have been employed as youths under the conditions prevailing before exhaust appliances were installed, and so may then have received damage. On the other hand, up to age 30 no excess respiratory sickness was found. This would suggest that modern conditions of work are satisfactory, were it not that some years of exposure to the dust is nearly certainly necessary before the effect of environment can become manifest in sickness-absenteeism. Undoubtedly the extreme conditions of the past no longer exist, and no longer are advanced cases of asthma being produced, but years must yet elapse before the question can finally be answered as to whether exposure to dust and fibre is to-day below the threshold of harm. This report establishes that, by adequate statistical treatment, sickness records can be used to disclose the existence of some occupational hazard, which is in itself no small advance in method; but it also makes apparent how much time must often have to pass before the benefit accruing from some measure of betterment can be demonstrated.

THE PROBLEM OF TRACHOMA.

FOR more than a century the causation of trachoma —or Egyptian ophthalmia, as it was called after it was disseminated among the British garrison in Egypt during the Napoleonic wars—has been one of the standing puzzles in ocular pathology. As is well known, it commences insidiously and runs an extremely chronic course; untreated cases eventually get involvement of the cornea (pannus) and such scarring and contraction of the tissues of the upper eyelids, involving inturned eyelashes, as is irremediable except by operation, and not always by that. The disease is rife throughout the east of Europe, Egypt, and the whole of Asia, and among some of the Indian tribes of North America. It appears to be favoured by conditions of dirt and bad hygiene, and it is undoubtedly contagious. The problem of its pathology, after having eluded the labours of more than one generation of investigators, appeared to have been solved a few years ago at the Rockefeller Institute in New York by Noguchi, who discovered a Gram-negative aerobic bacillus with which he succeeded in infecting chimpanzees with what was acknowledged, even by his critics, to be, at any rate in some cases, true trachoma. More recent investigations have, however, failed to confirm his findings, and experiments are still being carried out at the Rockefeller Institute. The appalling fact is that, taking the world over, there are more people blinded as the result of trachoma than from any other single cause.

In the struggle to cope with the evil the experience of two countries is especially notable: Egypt, where, owing to the liberality of the late Sir Ernest Cassel and the initiative of English ophthalmologists, the ravages of trachoma are being to some extent checked by a system of travelling tent-hospitals; and England, where the problem has never been present except on a comparatively small scale, but in London at any rate, was far more serious 30 years ago than it is now. This improvement is to be attributed to the isolation of infected cases until they are cured. This policy is described by Dr. Francis Lavery in his Montgomery lecture on trachoma in Ireland, an abstract of which appears on p. 1163 of this issue. The extent of the evil in that country seems to be much graver than had been realised, for though among the general population trachoma is less prevalent now than formerly, yet in several institutions under the direct control of a public authority no attempt to prevent the spread of the infection among children has succeeded. This is shocking, and we trust that Dr. Lavery's revelations will prove a spur to the authorities to take action in the direction indicated by him. In civilised countries trachomatous pannus and entropion from inverted lids ought never to be seen, for trachoma is a disease which, if diagnosed in its early stages, and treated efficiently for a sufficient length of time, can be cured without material injury to the sight. In countries where the disease is rife the routine examination of all school-children by oculists skilled in detecting its early signs is the first condition for its eradication.

FOOD FUMIGATION.

PRUSSIC acid is being used not only for ridding ships of rats but for the destruction of insects of various kinds in imported dried fruit and other foods. The absence of any destructive effect on structures and fittings gives it an advantage over most other poisonous gases, and it possesses the further advantage of being easily removed by ventilation. If we knew exactly the extent to which foods of various kinds may absorb hydrogen cyanide, we should then have the answer to the question whether, and in what circumstances, the gas may safely be used for the destruction of vermin and insect pests. A monograph by Dr. G. W. Monier-Williams just issued[1] by the Ministry of Health, collates and discusses the available data. It appears from this very interesting report that of recent years the generation of hydrogen cyanide from potassium or sodium cyanide and sulphuric acid has been abandoned and either the liquefied acid (its boiling point is 25° C.) is used from cylinders or, mixed with a lachrymatory, is absorbed in kieselguhr and stored in sealed tins. A crude calcium cyanide is also used. Foods retain varying amounts of hydrogen cyanide after treatment and part with what is retained at varying rates; retention depends on such factors as moisture content, the nature of the surface, closeness of packing; probably also on the formation of not very stable combinations of some constituents of the food with hydrogen cyanide. Milk, fresh or dried, and dried fruits appear to retain relatively large amounts of the gas; as to cheese some doubt exists. Cooking is likely to decrease the amount retained. Dr. Monier-Williams suggests the need for special care in cases where high concentrations of gas or long exposures are adopted, and he considers 20 parts of hydrogen cyanide per million a reasonable maximum for fumigated food when exposed for sale. He also calls attention to the toxic action of hydrogen cyanide on the respiratory enzymes of plants and its results in the treatment of stored fruit. From the point of view of vitamin retention so closely associated with freshness, he considers caution desirable. Chapter and verse are given for all his conclusions.

WE regret to learn the death of Dr. Ewan Richards Frazer, which occurred on Nov. 15th. His pathological work and generous benefactions to science are well known to the medical profession.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCXII.

AFTER-TREATMENT OF SOME COMMON OPERATIONS.*

PART I.

SIMPLE LAPAROTOMIES.

AFTER any operation the aim is to achieve the speediest possible recovery by the simplest and most economical means with the minimum of suffering, and especially to avoid any disability, temporary or permanent, resulting from the operation itself.

One of the most frequent operations is a simple laparotomy without drainage, and I will first mention a few points in the after-treatment of such cases generally.

At the end of a general anæsthetic for laparotomy it is important not to remove, before the patient recovers consciousness, whatever means is in use to keep up a satisfactory air passage through the mouth, and the free escape of saliva and mucus must be provided for by propping the patient on his side with pillows; otherwise he will be partially asphyxiated, he will swallow mucus, and he will gulp in air, all of which conduce to vomiting; and if the patient does vomit, his discomfort is greatly diminished if he is not allowed to lie on his back during this period of semi-consciousness. At this stage it is advisable to give by rectum, in the average case, one drachm of potassium bromide and grs. 40 of aspirin in 5 oz. of water.

After a lengthy or exhausting operation this is followed by a slow drip (at the rate of about a half to three-quarters of a pint an hour) of 3 per cent. glucose in water, and this should be continued for several hours in cases of shock, collapse, or toxæmia, particularly if peritonitis is present. The continuous drip is much better tolerated than intermittent rectal injections and a much larger quantity can be given in less time by the former method. I never order saline solution by rectum, for water is more easily absorbed and less irritating, and the salt possesses no virtue; glucose combats shock, replaces carbohydrate deficiency, and prevents vomiting. Five per cent. glucose may be given with the same object intravenously in quantities from 100 to 1000 c.cm.

Pain.

The stage of restlessness during recovery from general anæsthesia, especially by ether, is inevitable and generally beneficial, for it speeds up the circulation of the lower limbs and diminishes the chance of thrombosis. It is noticeable that though the patient at this stage is restless and excited he is not usually conscious of much actual pain—a fact not always appreciated by the nurse in charge; a little patience, instead of immediate resort to morphia, makes for easier convalescence later on. The use of morphia to combat pain in these early hours can often be avoided if it is realised that the patient can usually be made comfortable by some simple device; almost invariably slight post-operative distension occurs within a few hours, and loosening the binder may be all that is necessary to relieve the patient's discomfort. At the end of an operation the abdominal binder is often applied too firmly, even tightly, and this is quite unnecessary. The lowest fold only should be firmly pinned round the pelvis, the other folds should be fastened loosely enough to allow a hand to be easily inserted under them, for within a short time the abdomen will swell and a tight binder then causes pain and probably conduces to vomiting. Another simple means of relieving abdominal wall tension is to place a high pillow under the knees. After 12 to 24 hours pain from distension often becomes severe; the distension may be masked by contraction of the abdominal muscles, but is detected by percussion of the left lower thorax, for it pushes the diaphragm up. For such pain any relief that morphia gives is very transient; morphia increases distension and so adds to the embarrassment of heart and respiration. A hot fomentation applied all over the abdominal wall relaxes muscular spasm and often gives great relief. For this pain also pituitary extract is most valuable; the dose is 1 c.cm. at all ages except under three years, when ½ c.cm. may be given. Where morphia is given after an abdominal operation one should be cautious as to the dose; gr. ¼ may be correct for a strong, healthy man, but more than gr. ⅛ or gr. ⅙ should not be given to a patient weakened by a severe operation. Heroin I distrust—it sometimes seems to have a specially toxic effect on the heart and there is a tendency to give it in too large doses. The correct dose is about one-third that of morphia in similar circumstances—i.e., gr. 1/24 or gr. 1/18; one must bear in mind that the official maximum dose of heroin is gr. ⅛.

Bowels.

As to the routine treatment of the bowels after a simple laparotomy my practice is to order a simple enema on the second morning, and this is repeated on the fourth and sixth mornings. Aperients during the first week may be dangerous—particularly cascara, infusion of senna, and castor oil; these drugs produce a copious secretion of succus entericus and a powerful contraction, even spasm, of the descending colon. The effect of these actions is sometimes to precipitate rapid and very dangerous distension of the small intestine and right side of the colon, proceeding sometimes to complete and fatal paralysis, especially if plastic peritonitis is present. Even after the first week enemata are often all that is necessary to evacuate the bowel, but some patients object to them; at this stage the most suitable aperients are confectio sennæ, drachms 1 to 2, or mag. sulph., drachms 1 to 2, or the following mixture:—

Extract cascar. liq.	℥ i.
Sod. sulph.	ʒ i.
Liq. ammoniæ	♏ xl.
Aq. chlorof. ad.	ʒ viii.

Dose ʒ ii. – ʒ iv. night and morning.

Sundry Points.

Bed Rests.—After laparotomies it is, of course, routine practice to sit the patients up, but it is not always easy to keep them so. It is not uncommon to see a patient lying on his back with only his head and shoulders propped up with pillows, a most uncomfortable position for anyone troubled with flatulence. He should be raised enough to make the whole trunk almost vertical, and can be kept from slipping if the ends of a firm knee-pillow are tied securely by cords to the bed rest itself.

* The substance of this article was read at the St. Mary's Hospital post-graduate course in October, 1930. Parts II. and III. will appear in future issues of THE LANCET.

In a vertical laparotomy incision the *stitches* must not be removed too early; my practice is to keep the stitches in for 14 days. They may cause some redness at the end of a week, but this fades during the second week as a rule. If infection of the abdominal wall takes place it is an indication to retain stitches in, rather than remove them early, for if they are removed convalescence may be much delayed by the resultant gaping wound, and it is unnecessary. For such infected cases—and they are rare if one carefully packs off and disinfects the abdominal wall while operating—the stitches can be kept in for over a fortnight if boric fomentations are applied.

As to *diet*, except after gastric and duodenal operations, the patient may be encouraged to eat normal food as soon as he will take it, and to drink as much as possible, aiming at five pints a day. To chew and swallow a biscuit or piece of toast will often stop post-anæsthetic vomiting; it empties the salivary glands and moistens and cleans the mouth.

Distension.—A common complication of abdominal operations, especially those on the gall-bladder and in cases of peritonitis, is severe distension and temporary paralysis of the intestines. To begin with, 1 c.cm. of pituitrin is given and half an hour later is followed by a turpentine enema. Meanwhile, hot boric fomentations are applied over the whole abdomen next to the skin; they can do no harm to the wound, however recent. As much fluid as possible is given, preferably by frequent small drinks, but if the patient is vomiting subcutaneous saline should be given continuously. If these methods fail to cause the passage of flatus from the bowel an enema containing two drachms of liquid ox bile in 5 to 8 oz. of water will usually be effective. If the condition continues and vomiting commences one must not wait long before considering the insertion of a small tube into a coil of small intestine; this can be done under local anæsthetic in such a way that the enterostomy closes itself within two or three weeks.

In persistent *post-operative vomiting* the passage of a small stomach tube is of great value and should be used with less hesitation than is customary; the stomach should merely be emptied, for washing it out with such solutions as bicarbonate of soda is uncomfortable and exhausting and of little, if any, value.

Thrombosis of the femoral vein is a troublesome complication of abdominal surgery. Probably the sitting position, with the vein partially obstructed by flexion and sometimes constricted by the lower edge of a binder, is a contributory cause of the clotting, and so also is limitation of the fluid intake. Abdominal cases should be encouraged to move their legs freely, especially for the first few days, and massage of legs and thighs should be carried out. General massage should be commenced during the second week and will minimise the giddiness and weakness that is felt when the patient leaves his bed.

Most laparotomies, of course, necessitate a three weeks' stay in bed, but exception may be made in the case of bronchitic old people, who should be lifted from bed to a chair on the fourth day. At this stage the abdominal wall is safely held by its sutures, and a short time out of bed makes the patient breathe deeply and diminishes the chance of basal pneumonia.

After operations on the intestines there is no need to limit the *diet*, for the consistency of their contents can be little altered. During the first week after an operation on the left side of the colon enemata are contra-indicated; Epsom salts provide the best means of liquefying the fæces here, and may be ordered as soon as the second day.

C. W. GORDON BRYAN, *M.C.*; F.R.C.S.,
Senior Surgeon to Out-patients, St. Mary's Hospital; Surgeon, Paddington Green Children's Hospital.

SPECIAL ARTICLES

CRIPPLES IN INDUSTRY.

A JOINT Conference arranged by the Invalid Children's Aid Association and the Central Council for the Care of Cripples was held at the Drapers Hall on Nov. 13th and 14th, with the general title of Problems relating to those handicapped by Physical and Psychological Defects. The subject of discussion at the third session was the Physically Disabled—Industrial Outlook, and the chair was taken by Mr. J. J. LAWSON, Parliamentary Secretary to the Ministry of Labour, in the absence of Lord Amulree. Mr. Lawson referred to the King's Roll, established in 1919, under which at present more than 26,000 employers had absorbed some 370,000 disabled ex-Service men into industry. He wished a similar arrangement could be arrived at for absorbing those injured on the industrial battlefield, and he believed that it could be done without penalising the industries concerned. The Ministry of Labour was prepared to support by any means in its power, financial or otherwise, those societies working for the help of cripples.

Dame AGNES HUNT spoke of the training scheme which had been in existence at the orthopædic hospital at Oswestry for three years. In considering the question of employment, cripples must be divided into two categories. The first—those whose disablement did not preclude them from employment in the open labour market, after efficient training—could be largely placed in posts through county orthopædic associations, though there were still districts where no such associations were at work. The second group consisted of people so severely crippled that their chance of employment in the outside world was negligible. The real solution for these cripples was a wide extension of the village settlement system. It was essential for them to be near their work and under medical supervision. For a training college or settlement to compete in the open market an efficient business manager was a necessity; if the capital expenses for hostels, shops, machinery, and living quarters were supplied by Government or the charitable public, a village settlement could reasonably hope to pay its way. Industrial cripples presented an even more difficult problem. The majority of these injured men had wives and families, and fear of being passed for light work—a form of employment which everybody knew was not available—had produced more traumatic neurasthenia than anything else. Common sense dictated that the industrial cripple should be treated under the same ægis as the cripple from disease; if he could be treated in an orthopædic hospital and passed on to a training college or village settlement, he would again become a wage-earning citizen, and would cease to feel that the world had no use for him. Orthopædic hospitals and training schools should employ their own crippled workers as

far as possible, and should keep a record of the subsequent employment of cripples who passed through their hands, as a guide to the best kind of training to be given.

Dr. JOHN F. WARD (Manchester Children's Hospital), speaking on the industrial outlook for the rheumatic child, said that this was really the problem of the child with heart disease, including the child suffering from the effects of chorea. In cases where, though damage had been done to the valves, the muscular walls of the heart were compensating well, the patient was actually improved by suitable occupation, slight exertion being helpful in keeping the heart muscles in good condition. Unfortunately, however, in many cases compensation broke down sooner or later, as insurance companies well knew. Sedentary occupations, such as clerical work, watch-making and repairing, rug-making, and shoe-making were the most suitable, and nothing which involved going up stairs or inclines should be considered. Outdoor employment was not inherently unsuitable, but the majority of outdoor occupations were too strenuous, and there was only a limited demand for such work as poultry farming and bee-keeping, which might be considered appropriate. The industrial outlook for the rheumatic child was not very bright, but it was not hopeless, and there were many cases in which a certain amount of useful work could be undertaken.

Dr. P. C. VARRIER-JONES said that the system of after-care for cripples in this country was one of chaos. There were a number of small schemes here and there trying to force men into industries which would not absorb them. A tuberculous man might be just as truly a cripple as one who had lost a leg or an arm; he was damaged permanently, and industry would not have him. Dr. Varrier-Jones made the practical suggestion that industry should be divided into two grades. First-grade industry would employ normal healthy people, and second-grade industry those who by reason of disablement could only work under special conditions. It was cheaper, as well as more humane, to let people earn part of their living than to keep them doing nothing. Second-grade industry must be efficiently managed, and there must be no waste or overlapping. The consumptive cripple could, in many cases, earn his own wages, but he could not pay a dividend on capital. A great economy had been effected by establishing a single business control for the Papworth and Enham village centres for disabled men. Formerly they were competitors, but now duplication had ceased, with the result that whereas in 1926 Enham's sales had been £12,000 and Papworth's £40,000, in 1929 they were £30,574 and £65,000 respectively. An enlightened system of coöperation was the only line on which a hopeful industrial outlook for the physically disabled could be anticipated.

Mr. J. T. BROWNLIE (ex-President, Amalgamated Engineering Union) said that, from his own experience, he thought the workers would gladly open their ranks to cripples, but the problem was really a question of wages. The trend of industry was towards elimination of waste, conservation of energy, and intensified competition, and it was not reasonable to expect an employer to pay the same rate of wages to a slow and semi-skilled worker as to one who was thoroughly efficient.

Miss DOROTHY WARD (After-care Association for Blind, Deaf, and Crippled Children, London) said that in 1930 1386 cases had been dealt with by the Association, of whom 1202 were cripples or heart cases. The Association had placed 495, 393 had placed themselves, 26 were on trial in various jobs, and 232 were still negotiating. She paid a tribute to the excellent training given to the children in school by London County Council teachers, and especially to those who managed not to allow technical training to interfere with reasonable proficiency in ordinary school subjects.

Miss EVANS (Hostels for Crippled and Invalid Women Workers, Denmark Hill) spoke of work being done among girls and women too badly disabled to obtain employment in the ordinary labour market. The cripples lived in three hostels, all within easy reach of King's College Hospital, besides being under regular supervision from their own medical officer. The workers were divided into wage-earners and non-wage-earners, the former being skilled needlewomen and receiving wages on the piece-work system. Though not self-supporting, they contributed substantially towards the cost of board, lodging, and medical attention. One hostel was reserved for more seriously disabled women; these could never contribute to their maintenance to any considerable extent, but by careful training some were able to produce good needlework which was sold for the benefit of the hostel.

Miss BATT (Council for Cripples, Manchester) said her Council had found it more profitable to train a few cripples in each of a number of trades than to concentrate on one or two types of training. Out of 600 cases investigated by the Council 230 were now working in a great variety of occupations, and this at a time when unemployment was particularly acute in Manchester.

Mr. F. POPPLEWELL (Office of Trade Boards, London) said that Trade Boards had fixed minimum wage rates in 40 trades in Great Britain, these rates being payable under penalty in all cases in which they applied. There was no particular difficulty in connexion with handicapped workers on piece work, but the situation was much more complicated when time workers were under consideration. The Trade Boards had power, however, to grant exemption on certain grounds to time workers incapable of earning the minimum rate by reason of physical disability, and this power was used quite extensively in response to applications, usually with some prescribed conditions.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

THE IMPERFECT CONQUEST OF MALARIA.

THE October number of the *Indian Medical Gazette* compares the results of antimalarial work in various parts of the world, and the comparison is not favourable to India. Not long ago I referred in these columns to malaria in Bombay. The conditions in Calcutta are, on the surface, very similar, and it is remarkable that the disease should be much less prevalent there. The general sanitation of Bombay is certainly no worse than that of Calcutta; *Anopheles stephensi*, which is the principal carrier in Bombay, is ubiquitous in Calcutta, and, in addition, *A. ludlowi*, the great malaria carrier of the Andamans, is breeding profusely in the Sunderbunds, not far from the city. Similar tropical conditions are also present in both cities, and yet malaria is said to be almost absent from the centre of Calcutta, and only lightly endemic in the environs, while it is rampant in the best parts of Bombay, as well as in the crowded bazaars. Apart from the household wells, which are

a conspicuous feature of Bombay, and furnish numerous breeding-grounds, it is difficult to assign a cause for this contrast, especially when it is remembered that breeding of *stephensi* goes on in cisterns, tubs, and water barrels, as well as in wells. A fact which should serve as a stimulus to Indian sanitarians is that malaria has been dealt with successfully on a large scale in other countries which present similar problems. Before the war Palestine was described as one vast malarial incubator, and the British and Indian troops suffered accordingly when they entered the country. Energetic measures were adopted during the period of hostilities, and after the war the campaign was taken up systematically under the auspices of the League of Nations, with the result that malaria now exists in Palestine merely as a minor disease. Reports from Algeria show that in the great plain of the Metidja, formerly a hot-bed of malaria, and in consequence the terror of the early French conquerors and colonists, as it had been before of the early Turks and Romans, similar results have been achieved. Thanks to the labours of the Sergent brothers, underground channels have been constructed, and other necessary measures taken, so that what was formerly an uninhabitable marsh, studded with lakes, is now a fertile area covered with orange groves and fields of wheat. Malaria still exists no doubt—quinine prophylaxis is extensively employed—but only in manageable proportions.

YELLOW FEVER.

The sanitary authorities of eastern countries are evidently still concerned about the possibility of the introduction of yellow fever. It will be remembered that the suggestion was even made some time ago, by a competent authority, that traffic by air between India and countries where the disease is endemic should be prohibited. Attention has now been drawn to the possibility of danger arising from the introduction of yellow fever virus for purposes of experimental study, and it is notified that the Indian Government had prohibited such importation into India, and the Dutch Government has taken the same step for the Dutch East Indies.

DEVADASIS.

While many of the Indian States are conservative in comparison with British India, not only in political but social reforms, some of their rulers, particularly those who have been educated on Western lines, have shown great initiative and a lofty spirit of idealism. The late Begum of Bhopal exercised, in many ways, a beneficent influence in her State. The Maharajah of Gondal (an Edinburgh medical graduate) is noted for his interest in education and public works. Now the Maharanee Regent of Travancore has taken action in a matter which has so far defeated all the efforts of reformers in British India. During a recent tour in her State, the Maharanee happened to visit a temple for worship. On finding that dancing girls were kept there, she issued an order abolishing the practice, and suggesting that in future men should be employed to perform the ceremonial duties.

A CONGRESS HOSPITAL.

Most of the hospitals and colleges started under the auspices of the Indian National Congress have proved to be failures, and students who have relied on them for their education have lived to regret this form of patriotism. On the other hand, the Congress Free Hospital, which came into existence in Bombay in June of the present year, as a kind of by-product of the *satyagraha* campaign, appears to have achieved some measure of success. The main object of its foundation was to give prompt medical relief to those persons who receive injuries in the conflicts between the police and the public in connexion with congress activities. It was originally established in the house of a benevolent *shroff* (jeweller), but has now been extended to 100 beds. Eminent medical men, actuated partly, it is to be feared, by resentment at the withdrawal of recognition of Indian degrees, give their services free, and supplies are furnished by voluntary contribution. The non-medical staff are also volunteers, and patriotic ladies assist in nursing. The ambulance arrangements are extensive. They include five cars, one of which, presented by a minor chief, has been converted from *shikar* purposes. Ayurvedic as well as Western treatment is employed, and large numbers of cases, both in- and out-patients, have been treated.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

ENDOWMENT OF MEDICAL SCHOOLS.

Johns Hopkins Medical School receives two important gifts from recent appropriations of the General Education Board. A half-million dollars goes to the completion of the William Osler medical clinic and of the William Stewart Halstead surgical clinic. The department of medical history, which has already received a million dollar endowment from the Board, is now given in addition $12,500 for each of five years and a capital sum of $250,000, making possible the provision of a larger faculty for the department which, it will be remembered, is under the direction of Dr. William H. Welch. It is announced that Dr. Fielding H. Garrison, who was recently appointed librarian of the W. H. Welch medical library, has also been appointed resident lecturer in the history of medicine. The University of Chicago receives at the same time a million dollars towards the fund—double that amount—needed for the construction, equipment, endowment, and maintenance of two buildings to house respectively the department of hygiene and bacteriology and the department of anatomy.

COST OF INDUSTRIAL MEDICAL SERVICE.

Continuing its inquiry, the Committee on the Costs of Medical Care has examined the industrial medical service of the Endicott Johnson Company, with factories in New York State, employing some 15,000 people. In 1928, the year of the survey, the company had assets of over $26,000,000 and its net sales amounted to nearly 70 million dollars. The medical service originated to meet the requirements of the State Workmen's Compensation laws. In 1916 one full-time physician and one nurse were employed. The service expanded by the desire of the workers. In 1918 the difficulty of distinguishing between those who could and those who could not pay resulted in the decision to extend the service to all employees and to their immediate dependants. In 1928 there were 28 physicians, 4 dentists, 5 dental hygienists, 2 physical therapists, 67 trained nurses, 4 bacteriologists, 4 pharmacists, 17 technicians, and 16 clerks and assistants upon the company's pay roll. The cost of the medical service in that year amounted to nearly 900 million dollars, or $21.81 per person eligible to its service. Only 6 per cent. of those eligible failed to make any use of the service during the year. Half of these used no medical facilities whatever.

SHOULD CANCER BE REPORTABLE?

The proposal of the State of Illinois to add cancer to the list of reportable diseases does not commend itself to the President of the Illinois State Medical Society, who argues[1] that personal cancer is in no sense a public menace. His second objection is based on a presumption that the health department would not guard the list of notified cases from inspection and copying. Should this occur it would be possible for the numerous purveyors of quack cancer "cures" to secure for themselves a long "sucker" list, to use the expressive language of this country.

NOISE ABATEMENT COMMISSION.

After 12 months of research and investigation by otologists, neurologists, engineers, acoustic specialists, lawyers, and others, the report of the New York Noise Abatement Commission has been published. The following observations are selected by *Health News* as the most significant resulting from the Commission's work:—

Hearing is apt to be impaired in those exposed to constant loud noises.

Noise interferes seriously with the efficiency of the worker It lessens attention and makes concentration upon any task difficult.

In the attempt to overcome the effect of noise, great strain is put on the nervous system, leading to neurasthenic and psychasthenic states, and necessitating frequent recuperation in the country to maintain mental efficiency and alertness.

Noise interferes seriously with sleep, even though in some cases it appears that the system is able to adjust itself so that wakefulness does not result.

It is well established that, in addition to other evil effects, the normal development of infants and young children is seriously interfered with by loud noises.

The newspapers coöperated with the Commission by inviting complaints from the public regarding specific noises. The noises most frequently complained of included outdoor loud speakers, steamship whistles, pile-drivers, subway and elevated trains, riveting machines, and automobile horns. The Commission is able to suggest methods by which many of the objectionable noises can be diminished or eliminated, but the extent to which these methods can be applied will depend largely on public interest in the question.

SEX-INCIDENCE OF UNDULANT FEVER.

The element of occupational hazard in the epidemiology of undulant fever is well shown in a recent study of undulant fever in the State of Iowa. Of a total of 375 cases in the State 77 per cent. were in males. Among 186 adults living on farms 87 per cent. of the cases were males. But among 125 patients who had no direct relation with livestock or carcasses 51 per cent. were males. The commonly found disproportion of males in all studies of sex-incidence of this disease is evidently due, not to any greater susceptibility of males to the infection, but to the more frequent exposure of men than of women to the hazards of butchery and the care of stock.

DIPHTHERIA IN NEW YORK.

Immunisations against diphtheria in New York City were increased from 47,500 in 1928 to over 211,000 in 1929. In the first eight months of 1930 there were 216 deaths and 4107 cases less than in the corresponding months of 1928, and 305 deaths and 4458 cases less than the average for the corresponding months during the previous six years.

(FROM OUR OWN CORRESPONDENT.)

CLASSIFICATION AND CONTROL OF NOISES.

THE Touring Club of France has published a vade-mecum for the benefit of the citizen who may wish to know the extent to which he may go within the limits of the law in protecting himself against the noise nuisance. It is quite remarkable how much the legal scales are tipped in favour of silence-lovers; they have only to know their rights, and to be willing to exercise them, in order to surround themselves with a zone of comparative silence. The secretary-general of the Touring Club, Mr. André Defert, a barrister, has recently pointed out to a representative of *Excelsior* how the special noise commission of this club was composed of members with expert knowledge of each kind of noise nuisance. The director-general of the State railways assumed responsibility for the noises of this service; a high official of the port of Rouen was the specialist in noises of the sea and rivers. The mayor of Deauville took charge of the noises from which residents of popular resorts suffer most, a high police authority had to deal with traffic noises, and another official had specialised in those noises of which persons living in the neighbourhood of aerodromes complain. Even the noise of church bells and the like had its special expert—a canon. Many people have a subconscious predilection for noise of this kind, and there is said to be something lugubrious about the modern American village from which the sound of church bells has been banished. But as a concession to the late morning sleeper the Angelus will henceforth toll in France at 7 instead of 5 A.M. As for the whistlings of railway engines, they are no longer to be heard on entering every station, at every turn in the line and level crossing, but only in certain cases. Similarly, the pilots who have hitherto found expression for their gaiety of heart in an almost uninterrupted chain of hoots as they pass between river banks lined with would-be sleepers are to be severely rationed. The silencers already imposed on motor-cycles will soon be compulsory for aeroplanes. With regard to the so-called musical instruments, the law as well as popular sentiment is unequivocally on the side of the audience. A mayor has, for example, a right to muzzle at night the calf, donkey, mule, or dog which makes itself objectionable by untimely noises. Even the cock which crows at night is subject to a mayoral interdiction. In the same category may be placed the talking film, the sponsors of which may be forced to take certain precautionary measures when their premises adjoin a dwelling-house. The most important lesson which this vade-mecum drives home is that there already exist effective powers for the control of the noise nuisance; and the public is advised to adopt a bellicose rather than a suppliant attitude towards the authorities. A practical outcome may be the establishment in Paris of a flying brigade of police to be known as the *Brigade du Silence*.

PASSING OF THE *Maisons de Tolérance*.

Another nail in the coffin of the official brothel was hammered home at Grenoble during the Seventeenth National Congress of the Radical and Radical-Socialist party, which adopted unanimously the following resolution proposed by Dr. Hermite and supported by a late Cabinet Minister, Mr. Justin Godart:—

The Congress, being inspired by the resolution adopted by the League of Nations' Committee for the Protection of

Women and Children, considering that its investigations made in the countries adherent to the Pact have enabled it to prove incontestably that 29 great nations which have abolished the traffic in brothels have declared that this abolition has in no way provoked any increase in the incidence of the venereal diseases, has done nothing to injure the public welfare, and has considerably reduced the dangers of the international traffic in women, addresses its congratulations to the municipalities which have closed the brothels, and notably the municipality of Grenoble, and takes note of the achievements, satisfactory from all points of view, thus effected.

The resolution ended with expressing a wish that a general order would be given with a view to the irrevocable suppression in France of the "scandalous trade" in *maisons de tolérance*. However much obscured in the drafting, the meaning of the resolution is perfectly clear: it is death—sooner or later—to the brothel.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

THE HOSPITAL SWEEPSTAKES.

THE first sweepstake promoted on behalf of certain of the Dublin hospitals has proved successful to a degree beyond the hopes of the promoters. When tickets were first issued it was announced that a sum of £25,000 as minimum prize money had been deposited at the Bank of Ireland. As a matter of fact some £400,000 will be distributed in prizes, being 50 per cent. of the gross takings. The hospitals concerned will benefit to the extent of about £130,000, the remainder of the takings going in expenses and promoters' commissions. The hospitals which share in the present sweepstake are: Sir Patrick Dun's, Jervis-street, National Maternity, Children's (Harcourt-street), St. Ultan's, and the Dental. The drawing of tickets took place last Monday in the Mansion House, Dublin, under the supervision of General E. O'Duffy, Commissioner of the Civic Guard. The sweep is on the Manchester November Handicap, which is being run on Nov. 22nd. Meanwhile, arrangements have been made for another sweepstake, to be held on the Grand National Steeplechase next March. It is on a wider scale than the present venture, for 23 hospitals have agreed to participate. They are: Dublin, Jervis-street, Sir Patrick Dun's, Meath, Richmond, Coombe, National Maternity, Children's (Harcourt-street), Linden Convalescent Home, Children's (Temple-street), St. Ultan's, St. Patrick's (Mountjoy-square), Dental; in Cork, North Infirmary, South Infirmary, Erinville, North Fever, Dental; in Limerick, Barrington's, County Infirmary, Bedford Row Maternity; in Waterford, County Infirmary; in Louth, County Infirmary; in Donegal, Shiel. Of the sums to be distributed the Dublin hospitals will receive 64 per cent. and the Cork hospitals 18 per cent.

DEATH OF DR. O. F. McCARTHY.

The death occurred last week, after a short illness, of Dr. Owen McCarthy, resident medical superintendent of the Cork Mental Hospital. Dr. McCarthy had spent the greater part of his professional life in that institution, first as assistant medical officer, and later as medical superintendent. During the war he served in the Royal Army Medical Corps, holding a captain's commission. He was held in high regard by his professional brethren in the South of Ireland, and his tenure of office in the Cork Mental Hospital was marked by many reforms and improvements.

MEDICAL BENEFITS IN NORTHERN IRELAND.

Dr. James Boyd has been appointed medical officer to the Ministry of Labour, N.I., to superintend the working of this scheme. Dr. Boyd is honorary physician to the Royal Gwent Hospital, Newport, Mon.

The Minister of Labour for Northern Ireland has completed the appointments in connexion with the Medical Benefit Council, which is to be set up under the National Insurance Act. The Council is representative of varied interests, and Prof. R. J. Johnstone, M.P., has agreed to act as chairman. The medical men on the Council in addition to the chairman are, Emeritus Prof. T. Sinclair, Dr. David Gray, Dr. W. Lyle, Dr. J. N. McLaughlin, Dr. S. E. A. Acheson, and Dr. J. C. Loughridge.

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

RAMISECTION IN SPASTIC PARALYSIS.

THE report[1] by Dr. C. P. Symonds and his colleagues on the results of ramisection in six cases of spasticity in children operated on by Dr. N. D. Royle at Queen Mary's Hospital, Carshalton, in 1927, appears to be the final word. There are many in Australia who hold the view expressed in this report, but there are a number—including several surgeons of ability, whose judgment is beyond question—who practise the operation, and claim good results, which they attribute to it. Dr. R. B. Wade, senior surgeon of the Royal Alexandra Hospital for Children, Sydney, who has had an unusual opportunity of studying the effects of the operation, writing on the results of ramisection performed by him on 35 patients suffering from spastic paralysis says:—

"Ramisection has in my hands, I consider, given better results in this class of condition than I have had in the past with tenotomies alone, transplantation of tendons, resections of nerves (Stoeffel's operation), and my experience up to the present convinces me that the operation of ramisection plus tenotomy and re-education should be the operation of choice in cases of spastic paralysis."

The *Medical Journal of Australia*, in its issue of Oct. 11th, 1930, p. 505, devotes an editorial to the subject. It quotes the conclusions of Dr. Wade and Dr. H. R. G. Poate from the *Journal of the College of Surgeons of Australasia* of March, 1930, and also those of Dr. H. le Roy von Lackum of the New York Orthopædic Dispensary and Hospital in the *Journal of the American Medical Association* of Jan. 12th, 1929. It is stated that the operation, beyond doubt, has a certain value, and the editorial questions whether those who made the English report were justified in drawing negative conclusions of such a sweeping nature from a small series. This journal suggests that further assessment of the value of the operation is necessary, and that it would be best to place the matter in the hands of a special committee for investigation in centres where the operation is used. Such a committee should inquire into the condition of patients, both before and after operation, over a period of two or three years. It is felt that it is for the College of Surgeons of Australasia to take further steps.

Apart from the question of the value of the operation in spasticity, considerable attention has lately been directed to the sequel of left lumbar ramisection in Hirschsprung's disease. In this condition the results

[1] THE LANCET, July 19th, p. 127.

of operation are very much easier to assess, and the decision is not complicated by so many other factors as with spasticity. There can be no doubt that symptomatic cures follow the operation in many cases, although surprisingly little improvement is apparent on radiographic examination.

A SOCIETY OF PHYSICAL MEDICINE.

PROPOSED ASSOCIATION WITH THE ROYAL SOCIETY OF MEDICINE.

FOR many years it has been felt that practitioners of physical medicine might usefully unite in a body which could effectively represent their interests and forward their aims. (See THE LANCET, Nov. 1st, p. 980.) On Nov. 14th a society was formed, but its proposed policy did not satisfy a considerable group of those affected, and on Nov. 17th Prof. W. E. Dixon took the chair at a meeting representative both of the newly formed society and of those who dissented from its aims. He outlined the history of the movement and the formation of a body of "biophysical assistants" under the auspices of the Society of Apothecaries of London. It had then, he said, been thought necessary to form a society important enough to control these assistants and, if necessary, to hold an examination. This plan met with much criticism from general physicians, and Lord Dawson had suggested instead the formation of a new section or sections of the Royal Society of Medicine. Against that suggestion stood the objection that the Royal Society of Medicine did not deal with political matters, or with the merits of apparatus or of commercial concerns; it could not form a committee to state the views of any of its sections, nor could it institute an examination.

Lord Dawson, the next speaker, strongly urged the advantages of coöperation with a large and influential body like the Royal Society of Medicine. First and foremost, practitioners of physical medicine needed an organisation for coöperation and the exchange of ideas. The recognition and examination of technical assistants was a matter for the educational bodies, and for recommendations from a society like the Royal Society of Medicine. He assured the meeting that in practice there would be no difficulty about political activity of this kind on the part of the Royal Society of Medicine, and said that if in the future any such difficulty arose, then would be the time to consider the formation of an independent body. The constitution of the Royal Society of Medicine was designed to give the maximum of freedom and independent action to individual sections with all the advantages of coördination and prestige.

Dr. Fortescue Fox, Dr. W. J. O'Donovan, Dr. Albert Eidinow, Sir Leonard Hill, Dr. King Brown, Sir R. Stanton Woods, Dr. Kerr Russell, Dr. Hector Munro, Dr. M. B. Ray, and Dr. C. B. Heald then contributed to a discussion. The necessity for a representative body of physiotherapists in this country was urged from the point of view of international relations and of public health work. The possibility of forming a society and then approaching the Royal Society of Medicine for recognition was adumbrated, and it was agreed that it would be a mistake to form two societies. It was argued that the Council of the Royal Society of Medicine had refused to take any steps in a matter of medical education which had been strongly urged by one of its sections, but it was pointed out, on the other hand, that the Council had allowed the Section of Laryngology to arrange with the Colleges for a diploma in laryngology, and the Section of Obstetrics to appoint witnesses to appear before the Committee on Maternal Mortality. Lord Dawson assured the meeting that a committee of its members would receive sympathetic consideration from the Council.

Sir William Hale-White described the work and constitution of the Association of Physicians, and suggested that, if a society were formed, it should be on those lines.

Lord Dawson suggested the following resolution :—

"That a committee representative of the various aspects of knowledge and of opinions be constituted in order to explore a plan of forming an adequate representation of physiotherapy within the confines of the Royal Society of Medicine."

Several members suggested that the terms of reference were not wide enough, and Lord Dawson therefore proposed as an addition to his motion the words :—

"and, in the event of failure, to explore other avenues."

This proposal was seconded by Dr. Hector Munro and carried unanimously. The meeting instructed Sir Leonard Hill and Prof. Dixon to approach interested parties with a view to forming a committee.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. R. A. Clark-Hall is placed on the retd. list.

Surg. Lt. E. C. Johnson is appointed to *Revenge*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. W. P. Elford to be Surg. Lt. Comdr.

Surg. Sub-Lt. C. Seeley to be Surg. Lt.

Proby. Surg. Lts. T. J. Lloyd, R. D. Bradshaw, A. S. Pearson, and E. R. G. Passe to be Surg. Lts.

Surg. Lt. H. A. M. Whitby is appointed to *Ramillies*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. St. M. Carter, half-pay, late R.A.M.C., retires on retd. pay on account of ill-health.

Capts. L. Handy and M. J. Whelton to be Majs.

TERRITORIAL ARMY.

Supernumerary for service with O.T.C. : 2nd Lt. H. A. Raeburn, from Gen. List, T.A., to be Lt., supern. for serv. with Med. Unit, Edin. Univ. Contgt., Sen. Div., O.T.C.

R. F. Phillips (late Cadet, Christ's Hosp Contgt., Jun. Div., O.T.C.), to be Lt. supern. for serv. with Med. Unit, Univ. of Lond. Contgt., Sen. Div., O.T.C.

ROYAL AIR FORCE.

Flying Officer N. M. Jerram is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. W. Illius retires.

DEATHS IN THE SERVICES.

Lt.-Col. Alexander Haldane Stokes, late A.M.S., who died at Bedford on Nov. 13th at the age of 88, graduated in medicine and surgery in the University of Dublin in 1868, and took the doctorate in medicine in the following year, when he received his first commission in the medical department of the Army. In 1881 he saw service in South Africa, was in charge of the base hospital during the Transvaal campaign, and was mentioned in despatches. He also served with the Sudan Expedition of 1885, and was awarded the Suakin medal with clasp and the bronze star. He retired in 1890.

DONATIONS AND BEQUESTS.—The late Lord Brotherton left, among other bequests, £100,000 for the general benefit of the University of Leeds and £20,000 for charitable purposes to the cities of Wakefield, Leeds, and Birmingham respectively.—By the will of the late Dr. Walter Edmunds, of Putney, the Worthing Hospital receives £2000 to provide for four cots.

CORRESPONDENCE

PRACTITIONERS AND THE MENTAL TREATMENT ACT.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 8th you were good enough to publish the substance of a notice issued by the Board of Control in the following terms:—

"Medical practitioners who desire to be approved by the Board of Control for the purpose of making recommendations in respect of voluntary patients under 16 years of age, Section 1 (3), and temporary patients, Section 5 (3) of the Mental Treatment Act can obtain the necessary form of application by writing to the Board of Control, Caxton House West, Tothill-street, London, S.W., and marking the envelope 'M.T.D.' in the top left-hand corner. As the Act comes into operation on January 1 next, intending applicants should write for this form immediately. The Board cannot entertain applications for approval from medical practitioners of less than five years' standing on the Medical Register."

A similar notice was issued in other journals and newspapers but up to the present a very small number of applications have been received from medical practitioners for approval under the Act. It will, of course, be appreciated that the operation of Sections 1 (3) and 5 (3) of the Mental Treatment Act as from Jan. 1st next will be seriously handicapped unless there is a sufficient number of medical practitioners approved by the Board for the purpose of signing recommendations under those sections. In particular, a temporary patient cannot be received for treatment under Section 5 unless the recommendation has been signed by a medical man who has been approved by the Board of Control for the purpose; and if in any area there are no practitioners so approved, the medical profession may find themselves in difficulty in securing that their patients shall have the advantage of treatment under those provisions.

It is therefore a matter of urgent importance that an adequate number of medical men throughout the country should be approved, if possible, before Jan. 1st next. Medical practitioners seeking approval should write to the Board of Control, Caxton House West, Westminster, S.W.1, for an application form and should mark the envelope "M.T.D." Applications can only be considered from practitioners of at least five years' standing on the Medical Register.

I am, Sir, yours faithfully,

L. G. BROCK,
Nov. 13th, 1930. Chairman, Board of Control.

THE ALKALOIDS OF ERGOT.

To the Editor of THE LANCET.

SIR,—In reply to the communication by S. Smith and G. M. Timmis, which appeared in your issue of Nov. 1st, I would say that in my first letter—THE LANCET of Oct. 18th—I already mentioned sources of ergot of rye containing ergotamine—e.g., Hungary, Czecho-Slovakia, Portugal.

In the first place S. Smith and G. M. Timmis suggested that ergotamine did not exist in ergot of rye. They now suggest that ergotamine may be obtained from ergot of rye, but of not a "normal" infection by *Claviceps purpurea*. I do not follow these authors here. For a man who wishes to prepare ergotamine, the ergot containing this alkaloid is the normal one, since ergotamine possesses all the valuable therapeutic properties of fresh ergot of rye. I can only repeat that the value of ergot of rye depends on various factors as age, source, conservation, &c., and different samples are found to yield respectively ergotamine and no ergotoxine, ergotoxine and no ergotamine, and ergotamine and ergotoxine side by side.

The suggestion of S. Smith and G. M. Timmis that ergotoxine may be converted to ergotamine during the process of manufacture has been made long before without any foundation, and now S. Smith and G. M. Timmis appear to cast doubt on the conclusions of their own work, where they confirmed my previous demonstrations that the two groups of alkaloids are chemically different and that a conversion also by other authors never has been observed.

I wish to repeat here my view that ergotoxine and ergotamine exist preliminarily in ergot of rye, but in varying quantity and varying proportion. We know similar examples of drugs with varying contents of alkaloids—e.g., cortex chinæ and others. As ergotamine loses its capacity to crystallise sooner than its pharmacological activity, insufficiently conserved or stored ergot of rye may occasionally give the impression that ergotamine is wanting, even if amorphous alkaloids are present.

I cannot agree with S. Smith and G. M. Timmis concerning their conclusion drawn from the pharmacological identity of ergotoxine and ergotamine regarding the clinical virtues of the two alkaloids. The clinical comparison cannot be executed but by clinical investigation. Practice has proved in numerous cases the occasionally big differences between pharmacological and clinical experience, especially in actions on the nervous system. Assuming clinical identity of ergotoxine and ergotamine, differences of more technical importance—capacity to crystallise, solubility, stability, &c.—possess great significance.

I am, Sir, yours faithfully,

Basle, Nov. 6th, 1930. Prof. ARTHUR STOLL.

To the Editor of THE LANCET.

SIR,—Having read Prof. Stoll's letter published above may we, in concluding this correspondence as far as we are concerned, briefly summarise our views?

First, there is not the slightest doubt that the four ergot alkaloids are chemically distinct substances. This was one of the chief points in our original paper, and we have written nothing which could suggest that we cast doubt on this conclusion.

Secondly, there is good evidence, chemical, pharmacological, and physical, that the four alkaloids are closely related. The possibility that ergotoxine may be convertible to ergotamine cannot be excluded.

Finally, we have recorded that during our extensive examination of official ergot from all available sources, including specimens from the countries mentioned by Prof. Stoll, we have invariably isolated ergotoxine and ergotinine. In no case have we isolated ergotamine or ergotaminine, although the methods which we employed readily permitted the extraction of ergotamine from the unofficial fescue ergot. We offered a tentative suggestion that rye might occasionally, or possibly regularly in some districts, be infected by a distinct species of *Claviceps* giving rise to ergotamine. We have not found such

an ergot, and the suggestion was only put forward as a possible explanation of the controversy between Prof. Stoll and ourselves.

We are, Sir, yours faithfully,

SYDNEY SMITH.
G. M. TIMMIS.

Wellcome Chemical Works, Dartford, Kent,
Nov. 14th, 1930.

To the Editor of THE LANCET.

SIR,—The correspondence in your issues of Oct. 18th and Nov. 1st between Prof. A. Stoll of the Sandoz Works, Basle, and Drs. Smith and Timmis of the Wellcome Chemical Works, may appear to be chiefly of interest to chemists and pharmacists. So far as it concerns the obscure chemical relationship between the alkaloids ergotoxine and ergotamine, and the botanical identity of the ergots yielding them, that may well be the case. Ergotoxine was isolated and characterised by Barger and Carr in 1906, and simultaneously described as hydroergotinine by Kraft, while the description of ergotamine by Stoll and Spiro followed some 15 years later (1921). I was able to show with Spiro that the action of the two is absolutely identical, and there remained even some doubt as to whether they might not be the same substance. The fact that they are chemically different seems to have been settled by the recent paper by Smith and Timmis; these authors, however, raised a new point, in stating that they always obtained ergotoxine from the official ergot of rye, and always ergotamine from the ergot of a wild grass (Festuca). This gave the impression, reflected in an annotation in THE LANCET of Sept. 20th (p. 652), that ergotamine was the product of unofficial ergots. Prof. Stoll denies this, and Drs. Smith and Timmis seem puzzled by the discrepancy between his statement and their own experience, and ask for further information. These questions can safely be left to the chemists and pharmacists for investigation and settlement.

There is, however, another problem arising from Prof. Stoll's letter, which has a directly medical importance. I am inclined to believe, indeed, that its importance is much wider than that of any question concerning ergot. Prof. Stoll is concerned to defend "the importance of ergotamine as the active principle of official ergot of rye." From THE LANCET'S suggestion, that ergotamine is the product of an unofficial ergot, he is, on the facts presented by him, perfectly entitled to defend its claim to be *an* active principle of the official drug. His use of the definite article, however, is apparently intentional; for, in the same connexion, he states that "hundreds of experimental and clinical workers have shown that ergotamine possesses all the specific properties of official ergot. As yet no such clinical literature exists on ergotoxine. While in 1923 the British Pharmaceutical Codex still denied recognition to ergotoxine as a clinically efficient active principle of ergot, ergotamine already possessed extensive clinical literature," &c. The implication appears to be that ergotoxine, though pharmacologically identical, has failed as a practical therapeutic agent where ergotamine has succeeded, and that the latter, accordingly, is *the* active principle.

So far as they are concerned with matters of fact, it is impossible to question the accuracy of the statements quoted above from Prof. Stoll's letter. It is a fact that he can cite abundant and accurately recorded clinical observations to show that ergotamine does what is required of ergot in practice; it is a fact that no such records can be found for ergotoxine; and it is natural for him to quote the statement in the Codex as an authoritative summary of experience. Prof. Stoll cannot reasonably be blamed for using these facts for his own purpose. The actual statement in the Codex is as follows: "Ergotoxine has been used clinically for its action on the uterus, but it is disappointing and gynæcologists are now generally agreed that it is not the active constituent they want." A foreign reader, such as Prof. Stoll, would naturally imagine that a number of representative gynæcologists had met to discuss the results of trials scientifically conducted in their clinics, and had agreed upon this important conclusion. It would be difficult for him to suppose that, though ergotoxine had been known for about 15 years before he found ergotamine, it had, in fact, never received a proper clinical trial in the country of its origin; or that such a statement as that in the Codex could be based on a casual impression. These, however, are the curious and rather humiliating facts. Ergotoxine, described in England in 1906, has not to this day received a proper clinical trial; ergotamine, described in Switzerland in 1921, and identical in action with ergotoxine, according to laboratory tests, was promptly and adequately studied in the Swiss and German clinics. As a result, the long outstanding question, whether the specific alkaloids were responsible for the clinically desirable actions of ergot, was answered decisively and in a positive sense. That question could have been answered at any date after 1906, and until 1921 the knowledge and the material needed for its study were most easily available in England. It was not merely that nothing effective was done; what was said was worse than nothing, in that it was misleading to anybody who took it seriously. Those who, being scientifically interested, pressed for clinical trials which could give a definite answer, became all too familiar with the assurance that "clinical experience" had found the Liquid Extract (B.P.) "satisfactory"; so that, as this extract contained practically no alkaloid, the alkaloid was clearly not required clinically, however interesting its intense and unique activity might be to the laboratory worker.

It may be presumed that this was the kind of evidence on which the Codex based its dismissal of ergotoxine; at any rate, I know of no other on which it could have been based. I should, however, in justice to British obstetrics, acknowledge that, when this fundamental question had been practically settled abroad, Mr. Aleck Bourne, in alliance with my former colleague, Dr. Burn, produced by far the most elegant and convincing demonstration of the fact that the clinical action of ergot is due to the specific alkaloids. Since, however, Burn and Bourne used only ergotamine for their clinical experiments, they added yet another to the published records, which have made it plausible for Prof. Stoll to suggest that he discovered, not merely a slightly different alkaloid with the same action as the long-known ergotoxine, but the long-sought active principle of ergot.

I do not regard this case of ergot and its alkaloids as having much importance in itself. The question which really interested me—namely, whether ergot owed its value to its peculiar alkaloids or to some unspecific constituent—has been settled at last. I am now almost completely indifferent as to whether ergotoxine or ergotamine is used in practice; the action of both is that which I originally described for ergotoxine, and I had the pleasant privilege of coöperating in the pharmacological investigation of ergotamine as well. I should merely like to see the pioneer work of my chemical colleagues of 24 years ago

receive its proper share of recognition. If I am correctly informed, the present position is that British gynæcologists, having shown no real interest in ergotoxine or inclination to study and describe its action, are exhibiting a polite readiness to try ergotamine, and even, perhaps, to adopt it in their practice, now that careful descriptions of its action have been published by their continental colleagues. The case happens to be one of which the details are familiar to me, but I find no reason for supposing that it is the only one of its kind. It probably furnishes only a rather striking illustration of a general reluctance, of medical men in this country, to undertake clinical trials of anything new, under the conditions of scientific control needed to make the results worthy of record. Detailed discussion of the possible causes of this attitude is beyond the scope of this letter. Has it any affinity with the artistic timidity which provides a readier hearing, in his own country, for the British musician who disguises his name and his origin? How far is it due to an entirely honourable concern, lest clinical opportunity should be exploited for some private, proprietary interest? If that is the difficulty, it is hardly met by a tame receptiveness for what is done elsewhere, which merely gives a free hand to foreign interests. How far, on the other hand, is the attitude merely a symptom of a condition affecting clinical research of every kind in this country—a condition of which the ætiology and treatment have recently been brought under active discussion? Whatever the cause, the position is a serious one for the progress of therapeutic science in this country.

I am, Sir, yours faithfully,

H. H. DALE.

National Institute for Medical Research, Hampstead, London, N.W., Nov. 17th, 1930.

P.S.—You have kindly allowed me to see the further letters which are to appear in the same issue with this. Your readers will, no doubt, agree with Prof. Stoll that identity of clinical action can only be strictly proved by comparative clinical trials. On the other hand, when exhaustive tests in various laboratories, including those of Prof. Stoll's firm, have established a very strong presumption of complete identity in action between two alkaloids, the fact that clinical records exist for the action of only one of them does not weaken that presumption.

ELECTRO-SURGERY.

To the Editor of THE LANCET.

SIR,—I should also like to protest at the views expressed in your leading article of Nov. 1st. In my opinion, electro-surgery in this country has developed very considerably, and from my own observations abroad there are operators here whose technique and ability are in no way inferior. As one example may I mention the great experience of Mr. Sampson Handley in this direction. There are many others skilful in as many directions. Dr. Cumberbatch has done a world service in the development of diathermy technique. The reference to apparatus is unfortunate. British diathermy machines of to-day are quite satisfactory, and have as standard the multiple tungsten gap your article refers to. In the enucleation of tonsils, I have had the opportunity of testing the hæmostatic properties of diathermy.[1] I use British diathermy machines as I have found none better.

I am, Sir, yours faithfully,

Putney Hill, S.W., Nov. 12th, 1930. WARNER COLLINS.

[1] THE LANCET, 1930, i., 859.

A PLEA FOR MORE CAREFUL TONSILLECTOMY.

To the Editor of THE LANCET.

SIR,—During the last few years I have had to examine the throats of very many school-children in the L.C.C. area. This has shown to me the large number of cases in which the operation of tonsillectomy has been inefficiently performed. It is essential to draw attention to the fact and, as it is better to have figures to support statements, I have noted the results of the operation in 100 consecutive cases I have examined. Here is an analysis of results:—

Of the 100 cases, 47 had their tonsils cleanly and satisfactorily removed, 49 had tonsillar remains, and four had the tonsils removed cleanly but the palate grossly scarred and deformed. (By tonsillar remains I do not mean a small tag of lymphoid tissue adhering to the base of the tongue, but a large part of the tonsil left behind—anything from a quarter of the tonsil to the whole of it.)

I have classified the results in the table given below showing the places where the operations were done.

Place of operation.	Total cases.	Cleanly removed.	With tonsillar remains.	With deformed palate.
Voluntary teaching hosp. ..	14	4	10	0
Voluntary non-teaching hosp.	47	24	22	1
L.C.C. clinics	35	19	13	3
By private operation	3	0	3	0
Place of operation unknown.	1	0	1	0
Total	100	47	49	4

From my observations over a number of years, I am confident that a similar series would show similar results. It is not my purpose to decry the work of my colleagues as I am not at all sure that better work could be done by any individual under the existing circumstances. It is rather my aim to bring the facts vividly before medical men, so that an examination may be made into the methods which produce such very bad results.

It should be noted in the first place that there is no substantial difference in the results obtained in voluntary hospitals and those obtained elsewhere. I hold no brief for any special method of tonsillectomy. Every man tends to evolve his own technique, but it appears to me that there are three essential requirements to obtain a high percentage of successful tonsillectomies, and that the present poor results are due to a neglect of one or more of these requirements.

The first and most essential point is the administration of a continuous anæsthetic which gives the operator plenty of time and ensures relaxation of the parts. In this way it is possible to cope with the difficult as well as with the easy cases.

The second point is that the operator must have a means of illuminating the fauces efficiently. It is not possible to remove tonsils while groping in the dark.

The third point is that there must be an efficient method of hæmostasis, as it is impossible to make sure that the tonsils have been completely removed until all bleeding has been stopped and the fossæ examined at leisure.

With regard to the high percentage of failures in cases operated on in the voluntary teaching hospitals (as shown in my small number of cases) no one doubts the personal efficiency of the surgeons of the departments. If they themselves performed all the operations the failures would be few. It is the necessity for teaching junior men the job that leads to the non-success of the operation. Young men must be trained but the patient should not be made to suffer in the process. A continuous anæsthetic, therefore, is all

the more essential so that the supervising expert can take over from the novice if necessary.

I am aware that the routine adoption of my three essential points would lengthen considerably the average time of operation, but perhaps not to the extent that might be expected. In children I find it possible, with trained assistance, to remove tonsils by dissection under ether anæsthesia, up to six cases in an hour. In any case present-day results are so bad that modifications in technique will have to be introduced, let these modifications lead where they may.

I am, Sir, yours faithfully,

J. D. McLAGGAN.

Wimpole-street, Cavendish-square, W., Nov. 14th, 1930.

THE CHARTERHOUSE RHEUMATISM CLINIC.

To the Editor of THE LANCET.

SIR,—The clinic was first opened in October, 1928. Treatment is entirely free, and consists of weekly injections of stock vaccine.[1] During the first two years rather more than 500 patients attended, suffering from rheumatoid arthritis, osteoarthritis, fibrositis, lumbago, sciatica, and other forms of chronic rheumatic disease. No case, however crippled, who could be brought up the stairs, has been refused. An attempt has been made to follow up all those who have ceased their treatment, and to these—195 in number—letters were sent out. 111 answers were received. As 17 were returned through the dead-letter office, 62 per cent. of the patients replied. Those under treatment—176 in number—who had attended for more than a fortnight, were instructed to reply to a questionaire.

The results were then tabulated under three headings: Great improvement, including "cure," Definite benefit, No benefit. An analysis of the replies received from those discharged as "cured," or no longer attending, yields the following results :—

Class 1.	Class 2.	Class 3.	Total.
Great improvement, including cure.	Definite benefit.	No benefit.	
43 (38·73 %)	43 (38·73 %)	25 (22·5 %)	111

Total of Classes 1 and 2, 77·4 % ; Class 3, 22·5 %.

Class 1.—Of those "cured" or greatly relieved there were 14 cases of osteoarthritis, 15 cases of fibrositis, and 14 cases of other rheumatic conditions. The average number of attendances in weeks of the cases of osteoarthritis in this class was 20·4 (maximum figures being 44 and 38), of the fibrositic group 11·4, and of others 10·4.

Class 2.—There were 13 cases of osteoarthritis in this class, with an average attendance in weeks of 16·7 ; fibrositis 6, with an average weekly attendance of 17 ; and of other cases 12, with an average attendance of 7 weeks.

Class 3.—The average attendance of all types in this unsuccessful group was 11·2 weeks. From many of the replies received in this group and from a study of the records of the case cards, it would appear that the occurrence of reactions, general and focal, which had not always been revealed by the patient while under treatment, had in many cases acted as a deterrent to persistence with the treatment.

A similar analysis of the opinions of patients under treatment yields the following result :—

Class 1.	Class 2.	Class 3.	Total.
91 (52·7 %)	69 (39·77 %)	16 (9·65 %)	176

It was realised in conducting this part of the investigation that the veracity of these opinions might be vitiated by a possible tendency of patients under treatment to exaggerate, out of gratitude or from a sense of obligation, the benefit experienced. With this possible fallacy in mind, these opinions were collected with a careful avoidance of leading questions, combined with a certain amount of cross-examination to elicit specific reasons for the alleged improvement, when such was not spontaneously given. Such reasons, for example, as "can now kneel," or "can now go up and down stairs," or "can now walk without a stick," were frequent and striking.

Combining the figures obtained by the postal and personal questionaires, the following figures emerge :—

Class 1.	Class 2.	Class 3.	Total.
134 (46·68 %)	112 (39 %)	41 (14·2 %)	287.

Total of Classes 1 and 2, 85·7 % in 287 cases.

It might be urged that those who had failed to reply had received no benefit and were reluctant to state this, and that their total should be added to those of Class 3 in the above calculation. It appears, however, that laziness or inertia would probably account for a substantial proportion of the missing opinions, for an examination of the case cards, and our recollection of the condition of the patients when last seen, indicates that a considerable number of them had received appreciable, and in many cases substantial relief.[2] We are satisfied that not all of those who failed to reply can be fairly charged to Class 3 of the account, but even if they were, the figures would stand as follows :—

Classes 1 and 2.	Class 3.	Total.
246 (65 %)	108 (35 %)	354

It would appear, therefore, that some number lying between 65 and 85, and nearer the larger number than the smaller one, represents the percentage of those who have undergone treatment and benefited thereby. A conservative estimate of this number would be 75 per cent., and we suggest that it is no overstatement of our case to advance the claim that three-quarters of those who have been under treatment at the Charterhouse Rheumatism Clinic have improved. We would like here to express our great appreciation of the courtesy of the Charterhouse Mission in Southwark, whose club room has so kindly been placed at our disposal for four afternoons a week.

In conclusion, it is our considered opinion that the method of treatment of the chronic rheumatic diseases by stock vaccine as used at the Charterhouse Rheumatism Clinic is one from which patients may be expected to obtain definite benefit. It is one upon which further detailed clinical research is

[1] The technique and the vaccine used is that described in the Handbook of the Vaccine Treatment of Chronic Rheumatic Diseases, Oxford Medical Publications, 1930.

[2] Several replies, which came in too late to be included, come under Class 1 or 2.

desirable, and since the method is suitable for the general practitioner to use in his own surgery, he should take an important part in any such investigation. We suggest that stock vaccine treatment could thus be applied on a large scale in the routine treatment of rheumatic patients, nor can we see any reason why it should not meet with a success equal to that here recorded.

We are, Sir, yours faithfully,

H. WARREN CROWE,
T. C. MCCOMBIE YOUNG,
FRANCIS BACH.

Nov. 13th, 1930.

PARAPLEGIA IN HODGKIN'S DISEASE.

To the Editor of THE LANCET.

SIR,—In the clinical note on the above subject published in your columns on Oct. 25th we overlooked by inadvertence an interesting clinical case showing similar symptoms which was also published in THE LANCET (1927, ii., 807) by C. F. T. East and R. C. Lightwood. We are pleased to repair this omission.

We are, Sir, yours faithfully,

F. JOHN POYNTON,
KENNETH E. HARRIS.

Harley-street, W., Nov. 18th.

PANEL AND CONTRACT PRACTICE

Maintenance of Efficiency.

IN his recent report on the state of the public health, Sir George Newman points out that, with two exceptions, the work of insurance practitioners is not subject to inspection of any kind. The exceptions, of course, are records and prescriptions. Yet, he adds, it would seem at first sight that the service is one in which some form of supervision is specially needed. It is not constituted by the appointment from a number of candidates of officers selected on account of their peculiar fitness for the work; on the contrary, any registered medical practitioner (other than one whose name has been removed from the medical list by the Minister) may exercise his statutory right to undertake the treatment of insured persons. How, then, is the efficiency of the service maintained? What steps are taken to ensure that insured persons receive proper treatment from their insurance practitioners?

The answers to these questions have been given in previous annual reports of the C.M.O., Ministry of Health, but he recapitulates them briefly:—

"First, reliance is placed on the natural tendency of the doctor to do his best for his patient. This, in my view, is an important consideration. Quite apart from the purely professional feeling of repugnance to inferior work, which is as strong among doctors as among members of other professions, there is between doctor and patient a relation of a very special kind. A patient is a person in distress, and the natural tendency of mankind is to relieve distress. A doctor is a person trained to give such relief, and it would be strange indeed if he required any outside prompting to induce him to do his best to give it. His relation to his patient is one that makes for an attitude of sympathy and mutual consideration. As a rule, patients are considerate to their doctors, and do not make unnecessary demands upon them. As a rule, doctors do their best for their patients. There are, of course, exceptions to both rules, but as I see the position they are few and far between.

"Secondly, the patient is free to choose his doctor, and if he loses confidence in the doctor of his choice he can make a change and choose another doctor. The change can take place at once if both the doctors concerned agree; and even if the first doctor refuses his consent to the change the insured person can effect it by giving 14 days' notice to the insurance committee. In insurance practice, as in other walks of professional life, a reputation for incompetence, carelessness, or neglect will result sooner or later in a reduction of clientèle.

"Thirdly, if an insured person thinks he has not received proper medical care from his doctor he may not only transfer his name to the list of another doctor but he may bring the grounds of his dissatisfaction to the notice of the insurance committee, who must then refer the matter to a subcommittee specially constituted to investigate such complaints. If the result of the investigation is considered by the insured person to be unsatisfactory it is open to him to appeal to the Minister."

Such, says Sir George, are the influences tending to maintain the efficiency of the insurance medical service, and (from the figures given in the report) it will, he thinks, be agreed that they are attended with considerable success.

"SOMETHING WRONG WITH CERTIFICATION."

Later in the same report Sir George Newman sets out the results of a special investigation into 81,375 cases referred during the year 1929 by approved societies to the regional medical staff, with an analysis of the proportion referred who ceased to draw benefit. It is difficult, he says, to resist the conclusion that in many of these cases a final certificate ought to have been issued at an earlier date, and that the societies may be compelled, for the protection of their funds, to refer, at an earlier stage of illness, cases normally producing only a short period of incapacity. In commenting on this passage, the *National Insurance Gazette*, while recording its belief that there is at least as high a percentage of honest men in the medical profession as in any other, holds that the point of view of certifying doctors needs further consideration.

"The average doctor takes the view that his patient engages him and that his sole duty is owed to that patient. That is the doctor's traditional attitude, and it was entirely correct in former times. It is only partly correct under the National Health Insurance system. The first part of the proposition is true, but the second part is not. The patient engages the doctor, but the whole body of insured persons pays the doctor's fees, and therefore a duty is owed to that body. The individual patient does not pay the doctor's bill. The whole body pays, and we put it to the doctors, as honest men, that a duty is owed to that body."

"In whimsical moments," the *Gazette* concludes, "it has struck us that an inscribed sheet of blotting-paper might be fixed in books of certificates, the inscription reading: 'I also owe a duty to the body which pays my bills.'"

Efficient Rural Service.

M.A., M.R.C.S. (Cumberland) writes: "Rural Panel, in his excellent but too short article, has forgotten one item—namely, the motor-car—which brings men out of the towns to those patients who think that a brass plate in a town means a more clever or capable practitioner. It is not difficult for a man with a large town panel to leave his work to an assistant, whilst he (the principal) is not only keen on augmenting his numbers and getting the mileage grant, but also uses these means to acquire private patients as well in the country.

"The country doctor cannot retaliate, for his mileage is already more than he can get through in a day without an assistant; and what real country doctor can afford to run an assistant or even a dispenser? There is now no 'fat to fry the lean.' The fat have migrated to the towns, leaving their ancestral halls tenantless. The lean are rapidly doing the same, some returning poorer than when they went, the town panel doctor following them up.

"The 'obvious advantages of a stable population' are rapidly becoming a thing of the past from the medical point of view."

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of three cities:—

Name of city and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 live births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.
Manchester.. (770,655)	16·9	15·3	1·40	1·47	4·1	2·0	97/37*	54	4·4
Newcastle-upon-Tyne (283,400)	18·1	13·8	1·35	1·37	2·6	2·3	85/40	50	5·8
Leicester .. (245,200)	15·3	13·9	1·30	1·45	3·5	1·8	80/32	45	5·3

Stillbirths per 100 live births: Manchester 5·8, Newcastle 6·4, Leicester (buried in the city cemeteries) 7·3.

* Among the 12,472 births in the districts covered by the health visitors. The total births were 13,032.

Manchester.

Dr. R. Veitch Clark says that in comparison with 1928 the birth-rate showed an increase of 0·11 and the death-rate an increase of 2·41. The chief causes of the increased death-rate were influenza, pneumonia, and bronchitis during February and March. Small-pox was introduced on four separate occasions. In all there were seven cases of the mild type and one of the confluent hæmorrhagic type, which proved fatal within seven days of onset. The fatal case was that of a male passenger, aged 34, on s.s. *Tuscania*. There were 761 cases of diphtheria, with 59 deaths, giving the high case-fatality of 7·8 per cent. Swabs were taken from the throats and noses of 1013 contacts and 50, or 4·9 per cent., were found to be harbouring the diphtheria bacillus. Most of these were admitted to Monsall Hospital and kept under observation until three successive swabs proved negative. In order to guard against unnecessary isolation virulence tests were carried out in 38 cases, with 21 positive and 17 negative results. Under the immunisation scheme, approved in June, 1928, about 3000 children were immunised. The diphtheria cases admitted to hospital were of a severer type than in the previous year, and many were admitted at a late stage. Seventeen of the 50 deaths in hospital occurred within 48 hours of admission. In order to cope with severe cases admitted late the intravenous administration of serum was adopted, with good results. With the consent of the parents, patients admitted for diphtheria were immunised against scarlet fever, and patients admitted for scarlet fever were immunised against diphtheria. Among about 1900 cases of scarlet fever admitted to hospital 500 were treated with serum. Dr. D. Sage Sutherland considered that the most marked reduction in complications among the serum-treated cases was in respect of adenitis, glandular disease, and nephritis, and that rhinorrhœa and otorrhœa showed little alteration.

There were 38 cases of enteric fever, 24 infected by *B. typhosus* and 14 by *B. paratyphosus*. In three of the typhoid cases mussels from layings known to be liable to pollution were thought to be the cause, and the dealers in Manchester have agreed not to market these mussels in future. All specimens of blood examined for the Widal reaction were also examined, but with negative results, for *Brucella abortus*. There were 37 confirmed notifications of encephalitis lethargica, in 10 of which the illness began in 1927, in 3 in 1928, and in 24 in 1929. The deaths numbered 24, seven being those of persons notified in previous years. Children suffering from after-effects are provided for at Swinton Home and adults at one of the municipal hospitals. The scheme for the provision of additional special institutional accommodation has been held in abeyance in view of the Local Government Act, 1929. The new cases of syphilis treated during 1929 were 1297 and of gonorrhœa 1768, to be compared with 1323 and 1683 in 1928. The number of defaulters remains about constant and approaches one-fourth of the total. In order to stimulate resumption of treatment letters were sent to over 2000 defaulters. From about half there was no reply; in 4·4 per cent. wrong addresses had been given, and in 20·2 per cent. the patient returned and attended satisfactorily. The new irrigation cubicles at St. Luke's Hospital have been greatly appreciated.

Dr. D. P. Sutherland, tuberculosis officer, reviews the results of artificial pneumothorax treatment begun in 1913 on a few cases at Abergele Sanatorium. Up to the present there have been 112 completed cases which have been under subsequent observation for six years. Dr. Sutherland finds that from 2·5 to 4 per cent. of all institutional cases in Manchester may be suitable. After six years about half the patients are dead, but the operation restores working capacity, reduces infectivity by the diminution or abolition of tubercle bacilli in the sputum, and limits the need for prolonged institutional care. Dr. H. G. Trayer says the post-mortem records for the past eight years at Baguley Sanatorium indicate a definite increase in the incidence of primary carcinoma of the lung, usually originating from a bronchus. Among 55 cases admitted for observation there were eight deaths, all of males. Two were due to pulmonary tuberculosis, five to carcinoma of the lung, and one to lymphadenoma. Dr. Trayer finds that in pulmonary neoplasm an initial hæmoptysis is twice as frequent and pleural effusion much more common. The incidence is higher in males than in females. In reporting on the work of the Manchester Cancer Committee, Dr. Clark mentions that two of the largest oil companies have sent their medical and scientific directors to investigate the work and give assistance. The Anglo-Persian Oil Company have sent one of their research chemists to Manchester to assist in the investigation of the cancer-producing properties of mineral oil and tar, and the Shell-Mex Oil Company are providing mineral oils in forms which the Committee's scientific staff desire to test, and sending crude oils from supplies in all parts of the world. The Committee has enlarged its scientific staff in order to expedite the investigation of the problem of mule-spinners' cancer. Particulars are given of the progress made during the year in the determination of the chemical composition of carcinogenic compounds.

The Regional Smoke Abatement Committee has a membership of 72 out of 102 authorities within a radius of 15 miles of Manchester. The Federation of British Industries has appointed a direct representative on the Committee. Much propaganda work, including courses of lectures at the College of Technology, has been carried out and efforts made to encourage the manufacture and use of smokeless fuels for domestic purposes. The Committee is at present only advisory and the question is again to be raised of its being constituted a statutory body. Lieut.-Colonel J. W. Brittlebank, M.R.C.V.S., reports that of 697 samples of country milk 12·6 per cent. were tuberculous. This is better than last year, when the percentage was 17·6. No great improvement can be expected, he says, until routine veterinary inspection is adopted. Among the 950 cows stalled in the city, three cases of tuberculosis of the udder were detected by veterinary inspection.

Newcastle-upon-Tyne.

Dr. Harold Kerr says the sunshine records at Armstrong College were 1211 hours, as compared with 1169 in the previous year, whilst at Cockle Park, near Morpeth, they were 1566 compared with a previous 1406. The city, therefore, lost one-fourth of the district sunshine. The atmospheric pollution gauges recorded a deposit of 1117 tons per square mile in the City-road, as compared with 839 in the previous year. This record is easily the worst in the country and is due to the grit and solid matter from the tramway's power station chimney. This gauge was moved to a similar industrial area in the St. Laurence district, where a deposit of only 340 tons was recorded. The tar deposit in City-road was 58 tons, as compared with 4 in St. Laurence, whilst the tar deposited in the residential district of West Gate Hill was 7 tons. The City-road gauge thus indicates excessive deposit and grossly incomplete combustion. The furnaces are overloaded and a powerful forced draught has been installed. Unfortunately the Electricity Board are about to move their plant to the tramways power station and there is no likelihood of the City-road nuisance being remedied for the next year or so. The use of smokeless fuel for domestic purposes is slowly increasing in Newcastle. Dr. Kerr has himself adopted coke fires with gas burners below the grate to light them and finds the method cleaner, less troublesome, and more efficient than with raw coal. He has also found a 10 per cent. reduction in the cost of gas and fuel without taking count of kindling wood.

Dr. Kerr submits a preliminary memorandum with a scheme for taking over Wingrove (poor-law) Hospital and bringing it up to date, but only in complete coöperation with the representatives of the voluntary hospitals.

The death-rate was only 0·7 up in spite of the influenza epidemic which was at its worst in the second half of February, but cleared up with the fine bright weather in the first week of March. There were 128 deaths from influenza; and respiratory diseases caused 15 per cent. of all deaths, as compared with 13 per cent. in 1928. There were 217 male deaths from cancer and 172 female, thus reversing the usual sex-incidence. Diphtheria was more severe and the case-fatality rose from 3·1 to 5·4 per cent. No immunisation scheme is in operation, but children admitted to the City Hospital for other complaints are immunised with the consent of their parents. There were two small defined outbreaks of enteric fever, one of 12 cases in February, which affected the surgical wards of the Royal Victoria Infirmary and caused one severe case in a nurse. Protection of the staff by inoculation, which has been for long a routine procedure of the City Hospital, has now been adopted at the Royal Victoria Infirmary. The other small typhoid outbreak included five cases with two deaths and originated from mussels gathered in the River Blyth. Dysentery was proved bacteriologically in 123 persons, ten belonging to outside areas, and there were four deaths. Dr. J. A. Charles, deputy medical officer of health, as the result of studying the history of dysentery in Newcastle, concludes that during the eighteenth century Newcastle was a veritable hotbed for it, whilst in the nineteenth century it appeared frequently in the records of the Newcastle Dispensary. The present outbreak which has gone on for two years is therefore a recurrence. It seldom occurs in infants under one year, is commonest in children from 1 to 2, most dangerous at the age-period 5 to 15, and the incidence and severity are greater for boys than girls.

At the venereal diseases clinic 38 per cent. of patients ceased attendance before the completion of treatment. The maternity and child welfare scheme is to be extended by the opening of three new centres, making 14 in all, and the appointment of nine additional health visitors, making 27 in all, with the object of giving greater attention to pre-school children and adequately serving the new housing areas. For a number of years Newcastle had a maternal mortality-rate about half the national rate, but for the last two years the rate has risen and in 1929 it was slightly above the national rate of 5·8. Confinements are equally divided in Newcastle between private doctors, midwives, and the Princess Mary Maternity Hospital. It is realised that this hospital is quite out of date as regards buildings and equipment and a proposal is on foot to have it transferred to a new site. At Barrasford Sanatorium a handicrafts shop was opened in August with a skilled instructor, mainly with the object of giving work to the patients which would occupy their minds healthily. There is, however, a ready sale for the goods made.

Out of 377 samples of milk examined, 8·7 per cent. were tuberculous, as compared with 3·7 in the previous year. One tuberculous sample came from a dairy in a neighbouring town with a considerable sale of steam sterilised milk in bottles! There are only 258 cows stalled in the city and amongst these the veterinary inspector found five tuberculous animals. There are 102 separate slaughter-houses in the city and no site has yet been obtained for the public abattoir to which the Health Committee has been for long committed. All the eight swimming baths are now equipped with a continuous system of filtration and aeration. Overcrowding is still prevalent, particularly among the very poor, to whom the 5496 municipal houses, built since the war, have brought no relief. Action with regard to insanitary property has been at a standstill. There are 1166 houses inhabited by 8720 persons which are classified as in insanitary areas; and there are also 143 houses inhabited by 1026 individuals which can be more appropriately dealt with separately. The new by-laws for houses let in lodgings are being enforced, but the bad planning and dilapidation of many of them is an obstacle. There is much overcrowding in these houses, with excessive rents.

Leicester.

Dr. C. Killick Millard says his health committee has made a very complete "declaration" under Section 5 of the Local Government Act, 1929, and that in consequence the North Evington (poor-law) Infirmary has, it is hoped, entered upon a new era of increased service to Leicester as the City General Hospital.

The marriage-rate continues to rise and the birth-rate continues to fall. In the last four years the former has gone up from 16·9 to 19·1, whilst the latter has gone down from 17·0 to 15·2. The death-rate, owing to the influenza epidemic, was higher than in any year since 1918. The pneumonia deaths (284) were more than in any year of the last decade. Influenza deaths numbered 214. For the week ending Feb. 23rd the general death-rate was 40·7, and in the following week 45·2. Three weeks later it was 14·0.

An interesting departure in the tuberculosis scheme was the opening in June of a seaside convalescent sanatorium at Holt, in Norfolk. The Ministry agreed that if the capital charges were met by voluntary subscriptions, the cost of maintenance might be defrayed out of the rates. The patients pay their own rail fare but incur no other expense. There are 22 beds and sanction has been asked for an increase to 26. The beds are occupied by women and children and by men for alternate three-monthly periods. The cancer control clinic, existing primarily to facilitate early diagnosis, is not used as anticipated, and the weekly sessions have become fortnightly ones. It is thought that the name frightens some people away. Possibly "cancer diagnosis" would have been less alarming than "cancer control." In 1927 the new cases of syphilis were 70 male and 75 female. In 1928 the new female cases rose to 104 and in 1929 the new male cases rose to 125. No adequate reason for this sudden increase has been discovered. The Leicester Health Committee raise no objection to the medical officers of the welfare centres giving advice on birth control to married persons, who consult them, in any cases where such advice seems to them to be called for.

In spite of all the house building, gross cases of overcrowding constantly come to notice and the great need in Leicester is among the poorest section of the community, who have not been benefited, as was expected, indirectly by a filtering-up process. Dr. Millard urges that the use of raw coal in all municipal offices should be discontinued, as such a step would give a great stimulus to the production of smokeless fuel. He himself has used smokeless fuel for three years with satisfactory results. He also has much to say in favour of sunbathing, and urges that Leicester should be a pioneer in this matter and make provision for sunbathers in its parks and recreation grounds. He adds weight to his advice by the statement that his remarks on the subject were penned in a secluded corner of his garden, whilst taking a customary sun bath in a costume that weighed exactly 1 ounce.

Dr. H. Stanley Banks states that of 313 scarlet fever cases treated in the hospital 172, including all the well-marked and severe cases admitted before the fourth day of the disease, were treated with scarlatinal antitoxin given intravenously. He gives particulars of the few complications that arose. The average stay in hospital for all scarlet fever cases was 21 days. He also finds that severely toxic cases of diphtheria, admitted on the third day of the disease or earlier, can generally be saved by very large doses of antitoxin given intravenously, and he claims that severe forms of post-diphtheritic paralysis have been practically abolished by this method. In all forms of infectious disease when middle-ear suppuration occurs zinc ionisation is carried out after a few days and repeated twice weekly until the ear is dry, and the result is said to be uniformly good.

The public analyst, Mr. F. C. Bullock, B.Sc., found formalin in two milk samples and boric acid in three cream samples. Two years' working of the regulations prohibiting the addition of preservatives to cream shows, he says, that the anticipated difficulties were largely exaggerated.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 8TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 92 (last week 87); scarlet fever, 2077; diphtheria, 1557; enteric fever, 55; pneumonia, 725; puerperal fever, 46; puerperal pyrexia, 111; cerebro-spinal fever, 11; acute poliomyelitis, 10; acute polio-encephalitis, 4; encephalitis lethargica, 11; dysentery, 22; ophthalmia neonatorum, 87. No case of cholera, plague, or typnus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 11th–12th was as follows:—Small-pox, 161 under treatment, 6 under observation (last week 183 and 3 respectively); scarlet fever, 1857; diphtheria, 2223; enteric fever, 18; measles, 85; whooping-cough, 104; puerperal fever, 24 (plus 9 babies); encephalitis lethargica, 122; poliomyelitis, 1; "other diseases," 42. At St. Margaret's Hospital there were 13 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 32 (0) from measles, 7 (1) from scarlet fever, 8 (1) from whooping-cough, 33 (6) from diphtheria, 86 (23) from diarrhœa and enteritis under two years, and 40 (3) from influenza. The figures in parentheses are those for London itself.

The fatal case of enteric fever outside London was reported from Wolverhampton. Measles accounted for 7 deaths at Bristol, 3 each at Walsall, Birmingham, Liverpool, York, Hull, and Gateshead. Birmingham reported 4 fatal cases of diphtheria. Diarrhœa accounted for 6 deaths each at Birmingham and Liverpool, 3 each at Stoke-on-Trent, West Hartlepool, and Gateshead. Influenza was credited with 5 deaths at Liverpool, 4 each at Birmingham and Manchester.

The number of stillbirths notified during the week was 270 (corresponding to a rate of 41 per 1000 births), including 43 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

THE NEW MOTORING REGULATIONS.

THE dates have now been fixed for bringing into operation the various sections of the Road Traffic Act. Most of the provisions of Part I., including those for licensing drivers, and those for careless and dangerous driving, will come into force on Dec. 1st, but the abolition of the speed limit for light cars and the new limits for heavier vehicles will not become operative until Jan. 1st.

On and after Dec. 1st the old form of driver's licence, which was granted without question as to the physical fitness of the applicant, will cease to be issued, but the old licences issued up to and including Nov. 29th will be valid until their normal date of expiry, with certain exceptions. A motor cyclist under the age of 16 will not be allowed to drive a motor-cycle after Nov. 30th unless he satisfies the licensing authority that he was in the habit of driving a motor-cycle for the six months before Jan. 1st, 1930, in which case he must surrender his old licence on Dec. 1st and obtain a new licence under the Act. A person under the age of 21 will not be allowed to drive a heavy vehicle unless he satisfies the licensing authority that he was in the habit of driving a motor vehicle of that class for the six months before Jan. 1st, 1930, and in this case also he must surrender his old licence and apply for a new one.

To obtain a driving licence under the new Act, a new form of application, known as "D.L.I.," will have to be filled up. Sections A and B of this form, providing for the formal application and for particulars of name and address, are similar to the forms under the old Act. Section C, however, is entirely new and is a declaration as to the physical fitness of the applicant. Three specific questions have to be answered. The first question is: "Do you suffer from epilepsy, or sudden attacks of disabling giddiness or fainting?" An applicant who answers "Yes" to this is absolutely debarred from obtaining a licence. Applicants who are in any doubt as to their answer are urged to seek medical advice, as the penalties for making a false declaration are severe. The second question is: "Are you able to read at a distance of 25 yards in good daylight (with glasses, if worn), a motor-car number plate containing six letters and figures?" A negative answer to this question will also debar an applicant from obtaining a licence. Applicants in doubt in this matter are also advised to seek medical advice, as the use of glasses may enable them to obtain the correct standard.

The disabilities mentioned constitute an absolute bar to applicants for driving licences, but a certain amount of relaxation is given in regard to the third question, which is: "Have you lost either hand or foot or are you suffering from any defect in movement, control, or muscular power of either arm or leg? If so, give particulars." If an affirmative answer is given and the applicant has not during the past six months been in the habit of driving a motor vehicle, he may sign Section D of the application form, which is a claim to undergo a driving test. If he passes the test he will be granted a licence, although certain conditions may be imposed as to the construction of the car to be driven. An applicant who gives an affirmative answer to this question and who has been in the habit of driving for the previous six months without danger will be entitled to a licence without test. Provision is also made for a disabled person

who wants to learn to drive in order to pass the driving test referred to, and he may obtain a provisional licence for three months, subject to the condition that he shall only drive when under the supervision of a competent instructor.

Part II. of the Act, which relates to compulsory insurance against third-party risks, will become operative on Jan. 1st, and the draft regulations will be ready in their final form next month. The insurance companies are preparing the necessary certificates. In cases where motorists are already adequately covered there will be no need to take further action; they will receive their certificates from their insurance companies in due course without having to apply for them.

WORKMEN'S COMPENSATION BILL.

In the House of Commons on Friday, Nov. 14th, Mr. LAWTHER moved the second reading of the Workmen's Compensation Bill, which substitutes for Subsection (4) of Section 9 of the Workmen's Compensation Act, 1925, the following Subsection:—

> If a workman who has so far recovered from an injury as to be fit for employment of a certain kind has failed to obtain such employment, he shall be deemed not to be able to earn wages and the judge shall order that his incapacity shall, for the purposes of this Act, be treated as total incapacity resulting from the injury for such period, and subject to such conditions, as may be provided by the order, without prejudice, however, to the right of review conferred by this Act:
>
> Provided that every such order shall be made subject to the condition that it shall cease to be in force if the workman receives unemployment benefit:
>
> Provided also that no such order shall be made if it is proved to the satisfaction of the county court that the workman has not taken all reasonable steps to obtain employment as aforesaid.

He said that this Bill dealt with the question of light work for partially incapacitated men. A miner, for example, might be suffering from miners' nystagmus, a scheduled disease admitted to be one of the most terrible from which a man could suffer. Yet within 6 or 12 months he could be taken before the medical referee, who would state that it was possible for the man to do light work, with the result that he was no longer entitled to full compensation. Hundreds of such decisions had been given, and it was because of the gross injustice that it was sought to bring about the change provided by the Bill. The Bill was not for miners alone, and similar cases could be found in all industries. If an injured man could not do his own job he ought to have full compensation.

Mr. ROWSON seconded the motion for the second reading of the Bill.

MOTION FOR REJECTION.

Sir W. GREAVES-LORD moved the rejection of the Bill. He said that the principle laid down in the Workmen's Compensation Act was that if a man was injured in the course of his employment he should get compensation if, as a result of his accident, he was unable afterwards to earn the same wages. Everything that was really a consequence of the accident was taken into account in awarding compensation. But the Bill left out of account altogether the question whether the failure to obtain employment was the result of the injury. Under the Bill the position would be this—if a man proved to a county court judge that he had an injury and that since his injury he had not been able to obtain employment, although his recovery was such that he was fitted for work, that man was to be considered by the judge as being incapacitated as a result of the accident unless the employer was able to prove that he had not reasonably tried to obtain work. The effect of the Bill would be to substitute for the Workmen's Compensation system a system of unemployment insurance and to put the whole burden of the insurance on the particular employer for whom the workman happened to be working at the time of his injury.

Major GLYN, in seconding the motion for the rejection of the Bill, said that the measure would lead to an enormous amount of litigation. The object they had at heart, to which the House would agree without dissent, was to make it clear that a workman who suffered injury as the result of his employment which prevented him from being the same useful unit in the industrial organisation of the country should be compensated for that injury. It was not right to say that every employer should be responsible for saying whether a workman had genuinely tried to seek work.

After further debate,

Mr. SHORT, Under Secretary for the Home Office, said that there was complete agreement that a grievance existed and that it must be remedied. The Government were prepared to give general support to the principle of the Bill. He could not give any figures as to the additional cost which the measure would entail. The Government would retain a free hand regarding amendments that might be placed on the paper in the Committee stage.

The Bill was read a second time without a division.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 12TH.

Medical Information on Birth Control.

Mr. FREEMAN asked the Minister of Health whether his attention had been called to the recent action of the Warwickshire County Council in authorising their medical officers to give medical information on birth control to married women; and, if so, what action, if any, he proposed to take in the matter.—Mr. GREENWOOD replied: Yes, Sir, I have been in communication with the Warwickshire County Council on this matter and have indicated to them the limited extent to which, in the view of the Government, maternity and child welfare centres may properly be used for this purpose. I am sending my hon. friend a memorandum which states the views of the Government on this question.

Sanatorium Accommodation in Kent.

Captain BALFOUR asked the Minister of Health the number of tuberculous cases awaiting admission for sanatorium treatment in Kent on Nov. 1st as compared with May 1st; and whether such cases awaiting admission included patients notified tuberculous on account of acute pleurisy.—Miss LAWRENCE (Parliamentary Secretary to the Ministry of Health) replied: The number of persons who were awaiting admission to residential institutions under the County Council's scheme was 99 on Nov. 1st, as compared with 81 on May 1st, the number of persons who were receiving treatment on these dates respectively being 595 and 559. These figures relate to persons medically recommended as suitable for residential treatment, and include any such persons who may have been notified as tuberculous on account of acute pleurisy.

Captain BALFOUR: In view of the fact that I can bring to the notice of the Minister specific cases where doctors have certified people as urgent cases and they have had to wait many weeks, will the hon. lady urge the County Council medical authorities to take steps to provide greater sanatorium accommodation?

Miss LAWRENCE: If the hon. Member will give me any cases I shall be delighted to inquire into them.

Medical Referees in Scotland.

Mr. STEPHEN asked the Secretary for Scotland if there were regulations for the guidance of medical referees under the National Health Insurance Act; and, if so, whether the rules laid down any period of time from certification by the panel doctor before the referee might question the seriousness of the illness of the person so certificated by his or her own medical adviser.—Mr. ADAMSON: The answer to the first part of the question is in the negative. Cases may be referred to the Regional Medical Officer for his opinion either as to capacity for work or state of health at any stage of the illness.

Mr. STEPHEN: Can the right hon. gentleman say who refers them to the regional medical officer?

Has not the panel doctor any authority in regard to the state of health ?

Mr. ADAMSON : The selection of cases for reference is made by the approved society or general practitioner concerned, and can be made either on a question of capacity or incapacity for work or in order to obtain a second opinion about the patient's state of health. Insured persons in receipt of certificates of incapacity for work from their panel practitioners can be referred at any time. It should be borne in mind that the medical referees merely express an opinion on the question of incapacity. The decision as to whether benefit should be continued or stopped rests entirely with the approved society, and though they may be influenced by the opinion expressed by the medical referees the matter is one for which they must accept complete responsibility.

Mr. STEPHEN : Is the right hon. gentleman aware that there is a great deal of discontent owing to the number of references that are made quite obviously without any real reason to the regional medical officer, and will he look into the matter and have it stopped ?

Mr. ADAMSON : If my hon. friend has any particular case brought to his notice I shall be prepared to have inquiries made about it.

THURSDAY, NOV. 13TH.

Milk for School-children.

Mr. ALPASS asked the President of the Board of Education what was the present position with regard to providing children with milk daily while attending school.—Sir CHARLES TREVELYAN replied : An increasing number of Local Education Authorities and teachers are coming to recognise the value of a daily ration of milk to children attending their schools. In the week ending Nov. 1st 35,000 children received milk free and 48,000 for payment, under arrangements made by the Local Education Authorities for the provision of meals. It is now estimated that 500,000 children, or about 9 per cent. of the elementary school population of England and Wales, are receiving a daily supply of milk under schemes organised by the National Milk Publicity Council. The corresponding estimate six months ago was 400,000.

Psittacosis.

Mr. CLARKE asked the Minister of Health the number of deaths attributed to psittacosis during the last three years.—Mr. GREENWOOD replied : The number of deaths registered in England and Wales during the period Jan. 1st to Sept. 30th, 1930, in respect of which psittacosis appeared on the medical certificate as a cause of death was 15. There were no deaths recorded from this cause in 1927 or 1928, but there was one death in 1929 registered as being due to broncho-pneumonia and septicæmia, which, as the result of the inquiry made in accordance with the usual practice of the Registrar-General, was attributed to psittacosis.

Tubercle Infection in Imported Cream.

Brigadier-General CLIFTON BROWN asked the Minister of Health whether, seeing that no precautions were taken to see that cream imported into this country was free from tuberculosis, he would take steps to see that it was subjected to similar examination for tubercle as milk under the Imported Milk Regulations.—Mr. GREENWOOD replied : I will consider the hon. Member's suggestion. I understand, however, that most of the cream imported from the Continent is sterilised, and I am advised that the danger of the presence of tubercle bacilli in such cream is practically negligible.

Town-planning Schemes.

Mr. D. G. SOMERVILLE asked the Minister of Health if, in the different town-planning schemes submitted to him, he was giving full consideration to the objections, properly formulated, of residents who considered that the proposals affected the amenities of the district in which they lived ; and whether an inquiry was held in all such cases.—Mr. GREENWOOD replied : The answer to both parts of the question is in the affirmative. The permission of development while a town-planning scheme is in course of preparation, however, rests with the local authority concerned, and there is no appeal to me against the granting of such permission. I have recommended local authorities to ascertain and consider the representations of persons likely to be seriously affected by any proposed development before granting permission for it, and I believe that local authorities generally observe the spirit of my recommendation.

B.M.A. and National Medical Service.

Mr. FREEMAN asked the Minister of Health whether he had received a copy of the proposal of the British Medical Association for a general medical service for the nation ; and what action, if any, he proposed to take in the matter.—Mr. GREENWOOD replied : I have received a copy of these proposals, and the principles on which they are based would, of course, receive careful consideration in relation to any further public provision of medical services which might be contemplated in future.

MONDAY, NOV. 17TH.

Medical Reports and Pension Claims.

Mr. STEPHEN asked the Minister of Pensions if he would arrange for a copy of the medical report upon which a claimant's claim to pension was refused to be given to the man upon his request, so that in doubtful cases he might be in a position to submit rebutting evidence from other high medical authority regarding the features of his claim.—Mr. ROBERTS replied : Claims are ordinarily determined in accordance, not with any single medical report but on the evidence of all kinds obtained, after consultation with the Ministry's medical advisers. It is not usually possible in the nature of the case to intimate to an applicant more than that the information furnished has not been sufficient to establish connexion between his present condition and his war service. This intimation is in fact given and the man is at the same time informed that he can submit any further evidence he may at any time have.

Preservation of School Medical Records.

Dr. HASTINGS asked the President of the Board of Education whether the medical records obtained as the result of the examination of school-children when they left school were preserved or destroyed.—Sir C. TREVELYAN replied : It is left to each local education authority to decide how long they shall keep the records of medical inspections of school-children, but I understand that they are generally kept for about five years after the children have left school.

Animals and Poison-gas Experiments.

Mr. FREEMAN asked the Secretary for War the method pursued for proving that poison gas experiments on living animals were applicable to human beings.—Mr. SANDERS replied : A comparison of the gross and microscopic appearance of the lungs of men killed by irritant gases in France with those of animals exposed to the same substance showed that the injuries were of similar nature and character, and further study of such animals gave evidence of the mode of action of the poison and their effects on vital organs. It was thus possible, by correlating these experiments with clinical observations on gas patients, to formulate curative treatments. There is no reason to believe that the connexion between the effect of gas on animals and its effect on human beings, which experience in the war established, does not continue to hold good.

Dissection of a Cat in a School.

Mr. BROMLEY asked the Home Secretary if he would make further inquiries into the case of vivisection of a cat in Haverthwaite school, with the view

of ascertaining the circumstances; and if he was aware that the cat was taken to this school alive in a bag by two of the boys and there chloroformed and dissected, and that some children were sick during this science lesson.—Mr. SHORT replied: A report has been received from the inspector who investigated the case. It is not stated whether the animal was killed on the school premises or not, but this point is of no importance with regard to the question of vivisection, which is the only aspect which my right hon. friend has any authority to deal with. The animal was painlessly killed one day and its body was dissected the next. This is not vivisection; it is entirely outside the Act, and my right hon. friend has no jurisdiction in the matter.

Drugs Manufactured from Opium and Coca Leaf.

Mr. MANDER asked the Home Secretary whether he had any information to show the amount of drugs manufactured from opium and coca leaf by the Soviet Union, Turkey, and India, respectively, in each of the past five years.—Mr. CLYNES replied: The following figures respecting the *Soviet Union* were supplied to the recent preliminary conference of Governments of manufacturing countries by the Soviet Delegation:—

	1927–28 Kilo.	1928–29 Kilo.	1929–30 Kilo.
Heroin	76	31	117
Dionin	426	334	436
Codeine	1946	1681	2884
Morphine hydrochloric	425	470	632
Pantopon	24	145	239
Cocaine	447	735	1120

Note.—These figures, having been telegraphically communicated to the Delegation, may be subject to revision in case of error in transmission. The Soviet Union economic year was originally from Oct. 1st to Sept. 30th. In accordance with the last decisions of the Union Government the economic year will begin as from 1931, on Jan. 1st, and end on Dec. 31st.

With regard to *Turkey*, figures of production of the drugs are not available, but the following figures of exports were supplied to the recent conference by the Turkish Delegation. According to the most recent statistics, the annual export of drugs amounts to 5216 kg. of morphine and 8652 kg. of diacetylmorphine. For the period Jan. 1st, 1930, to June 30th the amounts exported were as follows:—

MORPHINE.

Declared destination.	Amount exported. Kilo.	Declared destination.	Amount exported. Kilo.
Greece	1.680	Italy	399.867
Italy	642	France	277
France	180	Germany	95.90
Greece	2.777.700	China	60
Dantzig	766.500		

With regard to *India* the figures of production are shown in the following Table:—

Manufactured from—	Caffermine.*	Morph.*	Morph. crude.*	Morph. acetate.	Morph. tartrate.	Codeine.	Narcotine.
	oz.	lb. oz.	lb.	lb. oz.	lb. oz.	lb. oz.	lb. oz.
Nov. 1, 1924, to Oct. 31, 1925.	—	140 5	2000	14 11	—	2 2	19 15
Jan. 1, 1926, to Dec. 31, 1926.	—	234 3	4099	4 4	23 5	—	—
Jan. 1, 1927, to Dec. 31, 1927.	—	57	281	—	8 11	2 10	—
Jan. 1, 1928, to Dec. 31, 1928.	13	159 7	738	—	—	5 6	5 0
Jan. 1, 1929, to Dec. 31, 1929.	—	119 6	—	—	—	13 6	10 0

* Hydrochloride.

TUESDAY, NOV. 8TH.

Anæsthetics for Women in Childbirth.

Miss LEE asked the Secretary for Scotland whether the regulations allowed anæsthetics to be given to women in childbirth in prison maternity wards; whether any special diet was allowed to pregnant women; and, if so, what was the nature of such diet.—Mr. JOHNSTON replied: There is nothing in the Prisons (Scotland) Rules to preclude anæsthetics from being given to women in childbirth in Scottish Prisons if the prison medical officer considers it advisable and the prisoner consents. No special dietary scale has been authorised for pregnant prisoners; but the prison medical officer has power to alter diet if satisfied that it is necessary; and it is his duty to see that every prisoner has sufficient food.

Health Insurance in Scotland.

Mr. BUCHANAN asked the Secretary for Scotland if he was aware that certain approved societies, including the Prudential, had issued notices to their members stating that, as from Jan. 1st, 1931, they would not be eligible for benefit from national health insurance owing to their prolonged period of unemployment; and if he proposed taking any steps to deal with this matter. Mr. JOHNSTON replied: The answer to the first part of the question is in the affirmative. The approved societies to which the hon. member refers have acted quite properly in notifying their members of their position under the existing law. As regards the second part, my right hon. friend is in communication with the Minister of Health, and I am not at present in a position to add to the reply given by the Minister of Health on Oct. 30th last.

MEDICAL NEWS

Royal College of Surgeons of England.

An ordinary meeting of the Council was held on Nov. 13th, with Lord Moynihan, the President, in the chair. Dr. Frederick Grant Banting, *M.C.*, M.R.C.S., Professor of Medical Research in the University of Toronto, was elected an Honorary Fellow of the College. Dr. Banting is the first Member to receive this distinction.

The Membership of the College was conferred on the candidates whose names we gave on Nov. 8th as recipients of the L.R.C.P. (excepting A. L. Devi, H. R. Hovsha, A. H. Lendon, D. K. Mulvany). Diplomas in public health were conferred on the candidates whose names have been given, and licences in dental surgery on the following:—

E. C. Austen, Elsa M. Bennett, C. G. W. Brown, S. C. S. Brown, Frances M. Carter, H. D. Cockram, R. G. L. Coe, Helen Cruise, G. M. Davies, D. T. Davis, Braham Deggots, E. S. Edwards, W. M. Ellis, L. E. S. Ffytche, J. H. R. Gaffney, J. H. Glen, F. J. Goldsworthy, H. W. Handley, C. V. Harries, C. G. W. Harrison, C. W. Harrison, K. T. Henderson, J. J. Hinton, H. G. Hobdell, C. H. Hole, F. J. Hood, J. E. Ilott, W. H. Jennings, D. R. Jones, Mary King, A. G. Kirby, F. F. Leek, Malcolm McDowall, A. C. Maguire, F. F. May, E. A. Mayston, R. C. Moody, R. V. Mummery, J. K. Noot, T. D. Popplewell, T. D. Raby, C. P. B. Reed, Helen Shilton, Denis Smith, F. H. Stokes, N. G. Straschun, R. A. Sykes, D. V. Taylor, E. J. Taylor, E. Underhill, R. B. Walters, K. W. Whitworth, and H. M. G. Williams.

The congratulations of the Council were given to Sir Arthur Keith, the Conservator of the Museum, on being elected Rector of the University of Aberdeen. Mr. F. J. Steward was re-elected a member of the committee of management of the Conjoint Examining Board. Examiners and Assessors for the Primary Fellowship Examination to be held at Melbourne, Australia, in August, 1931, were appointed. The President reported that the terms of office of Mr. C. H. Fagge and Mr. Russell Howard on the Court of Examiners would expire on Dec. 10th next, and that the vacancies thus occasioned would be filled up on Dec. 11th, together with the vacancy occasioned by the death of Mr. T. P. Legg.

THE BUCKSTON-BROWNE ANNUAL DINNER.

Fellows and Members dined together in the library of the College on Nov. 13th, for the third time under the terms of the Buckston-Browne Trust, which stipulates that on this occasion at least half the invited guests shall be Members of the College. Lord Moynihan, who presided, recalled the circumstances of Mr. Buckston-Browne's generosity, and in spite of his protest his health was drunk with musical honours. In replying, Mr. Browne took the

opportunity of congratulating Sir Arthur Keith on his election as Rector of the University of Aberdeen. He explained the significance of a souvenir, presented by him to every guest present, in the form of a letter-opener, attached to which was a replica of a bronze catheter found in the house of a surgeon at Pompeii, and evidently more than 2000 years old. Each guest also received a descriptive list of Hunterian and other pictures in the museum collection, many of which have been restored with great skill by the staff at Down House before being returned to the museum. Among the invited guests Lord Moynihan welcomed Lord Chelmsford as chairman of the Post-graduate Medical Committee, and Mr. F. C. Goodenough, chairman of Barclay's Bank, to whom was due the opening of London House as a hostel for post-graduate students. The following is a complete list of those present :—

Council.—Lord Moynihan (President), Mr. C. H. Fagge and Mr. R. P. Rowlands (Vice-Presidents), Sir Holburt Waring, Sir John Lynn-Thomas, Mr. Ernest W. Hey Groves, Mr. F. J. Steward, Mr. J. Herbert Fisher, Mr. W. Sampson Handley, Mr. G. E. Gask, Mr. W. McAdam Eccles, Mr. Wilfred Trotter, Sir Charles Gordon-Watson, Mr. A. H. Burgess, Mr. Victor Bonney, Mr. G. Grey Turner, Mr. Hugh Lett, Mr. Leonard Gamgee, Mr. R. G. Hogarth, Mr. R. E. Kelly, and Mr. Graham Simpson.

Fellows.—Mr. John Adams, Sir John Atkins, Mr. W. Girling Ball, Mr. L. R. Braithwaite (Leeds), Mr. G. Buckston-Browne, Mr. P. W. L. Camps (Teddington), Mr. John Clay (Newcastle), Mr. H. G. G. Cook (Cardiff), Mr. R. S. Corbett, Sir T. Carey Evans, Mr. H. A. T. Fairbank, Mr. C. W. Flemming, Mr. E. C. Hughes, Sir Arthur Keith, Mr. W. H. Kelson, Mr. A. Harold Levy, Mr. Albert Lucas (Birmingham), Mr. Reginald T. Payne, Prof. A. W. Sheen (Cardiff), Dr. P. Montague Smith, Mr. A. M. Webber (Nottingham), Mr. Garnett Wright (Manchester), and Mr. H. Blacow Yates (Sheffield).

Members.—Dr. John Attlee, Sir George Badgerow, Mr. Henry Bailey (Leeds), Dr. S. M. Banham, Dr. A. E. Barclay (Manchester), Dr. D. L. Beath (Bath), Mr. W. R. Bett, Dr. G. E. Birkett (Manchester), Mr. H. E. G. Boyle, Dr. Cecil Bull, Mr. R. F. Bury (Leamington), Dr. Dennis Embleton, Mr. M. I. Finucane, Dr. G. E. Genge-Andrews, Dr. G. T. Giddings (Beckenham), Mr. Elliott T. Glenny (Clifton), Dr. T. A. Goodfellow (Manchester), Dr. A. Hunnard (Mansfield), Mr. C. I. Kirton, Dr. Arthur Lankester (Purley), Lieut.-Colonel L. E. Lanyon-Owen, Mr. H. O. Long, Mr. H. C. Malleson, Mr. F. H. Mayo (Leeds), Dr. E. C. Morland (*The Lancet*), Dr. T. Crofts Neville, Dr. Ralph Norman (Thorpe Bay), Dr. P. Seymour Price, Dr. A. W. Read, Dr. Leslie Reynolds (High Wycombe), Dr. H. B. Roderick (Cambridge), Dr. W. T. Rowe (Nottingham), Lieut.-Colonel C. T. Samman, Dr. Howard Stratford, Dr. Harold Waller, Dr. A. M. Ware, Mr. J. L. Whatley (Knowle), and Mr. H. Wood-Hill (Beccles).

Others present. — Viscount Chelmsford, Mr. F. C. Goodenough, Rt. Hon. Sir Francis Acland, Dr. Allen Mawer (Principal of University College), Prof. Henry Armstrong, Prof. C. J. Patten, Dr. H. R. Oswald, Dr. G. C. Peachey (Editor of the *Medical Press*), Mr. R. Scott Stevenson (Editor of the *Practitioner*), Mr. S. Forrest Cowell (Secretary, R.C.S.), Mr. R. H. Burne (Physiological Curator), and Mr. Kennedy Cassels (Assistant Secretary).

Society of Medical Officers of Health.

Prof. Harold Kerr took the chair at the annual dinner of this Society on Nov. 13th. After the toast of H.M. the King had been honoured, Mr. Arthur Greenwood, Minister of Health, proposed "The Society." He remarked that since the appointment of the first medical officer of health in Liverpool 80 years ago, medical officers had exercised a great and growing influence over the attitude of the people towards general health questions. They were slowly but surely teaching a healthy way of life, which was better than any prescription for a particular disease. The place of a nation in the eyes of the world depended upon the quality of the common stock. This country had the best common stock that the world produced, but was not making the best of it. The Society was a most powerful medium in the country for abolishing preventable disease, and its responsibilities grew progressively heavier as the importance of the problem was realised. The President, in reply, complimented the Minister of Health on his invaluable work in coördinating the many health organisations of the country and on his effective administration of the Local Government Act. He believed profoundly, he said, in the value of such a representative body as theirs. Not only did it voice the corporate opinion, but it brought members from different districts into contact and allowed them to compare their experiences and thrash out new problems before putting them into execution. Moreover, it was invaluable as a social medium ; he owed to it many of his best friends. It was the dream of the Society that the general practitioner should become a preventionist. Already, by removing the flow of sick babies from which in the old days the family doctor had derived much of his income, they had turned him from a cynic into a stoic. Alderman David Adams (Lord Mayor of Newcastle-on-Tyne), proposing the health of "The President," said that Prof. Kerr had so organised the health services of the city as to preserve the status of the general practitioner. Newcastle boasted of being easily the foremost city of the country in its zeal for public health improvement. Sir Arthur Newsholme proposed the "Guests of Honour." He recalled many famous names from the list of former presidents. In welcoming the great improvement in the relations between the Society and the British Medical Association, he accepted as a happy augury for the future the election of Dr. W. G. Willoughby to the Presidency of the Association. Sir Eustace Hill, in reply, illustrated by his reminiscences the rise of medical officers of health in popular estimation. Dr. Willoughby also replied. The general practitioners of his district, he said, had with him come to the conclusion that there was no such thing as "encroachment," but that there was a great deal of mutual assistance. All branches must trust one another and work together while preventable disease still remained to be conquered.

Presentation to Mr. G. S. Elliston.—Dr. G. F. Buchan then proposed the health of Mr. G. S. Elliston, who was retiring from the position of executive secretary of the Society which he had held for 12 years. When Mr. Elliston had come, he said, the membership had been 700 ; to-day it was 2000, and they owed to his powerful inspiration a measure of prosperity which they had never before attained. He presented Mr. Elliston, on behalf of the Society, with an engraved silver tray and a motor-car. Mr. Elliston, in reply, said that the debt was entirely on his side and that he had met with nothing but kindness and generosity from every member during his office. In 12 years he had only once proposed a question which Dr. Buchan had been unable to answer : that had been when a member had inquired about the mechanism for claiming a rebate on super-tax !

B.M.A.: Ninth Annual Council Dinner.

The Chairman of Council, Dr. H. Brackenbury, took the chair at the ninth annual dinner of the Council of the British Medical Association, held in the Great Hall on Nov. 11th. After the loyal toast had been honoured, the chairman proposed the health of the "Retiring Officers." Sir Ewen Maclean, he said, had been overseas at the time of his retirement last year, and the thanks which the Association owed him had accordingly been postponed until that evening. Prof. A. H. Burgess, although retiring, continued to represent the Association as Acting President during the year of office of Prof. Harvey Smith of Winnipeg. Prof. Burgess and Sir Ewen were alike in the physical world and in the world of physic ; their work on surgery and obstetrics was widely recognised, their services to the Association were acknowledged by all, and they shared a comforting gift of genial friendliness. They had both travelled overseas for the Association, Prof. Burgess to Canada, and Sir Ewen on his tour of the Dominions. Sir Ewen Maclean, in reply, presumed that the term "retiring" did not refer to his or Prof. Burgess's disposition. He claimed, however, to be the more retiring of the two, as his retirement would be perfect at the end of the evening while his colleague's would remain imperfect until the coming summer. The centenary celebrations in 1932 would show still more clearly what had so impressed him on his world tour : the stout bond between the profession in this country and overseas. Prof. Burgess, also replying, congratulated the officials of the Association and of the Canadian Pacific Railway on the excellent organisation which had made the Canadian visit so successful. The reception of the delegates by the Prime Ministers of each province and of the Dominion had shown that Canada regarded the Association as a great Imperial body. Mr. T. P. Dunhill, proposing the "Common Health," said that their organisation was necessary, not for their own protection but for their success in bearing the responsibilities of their profession. In so far as they kept in the forefront of their thoughts their opportunities for service, so far would they carry with them the approval of mankind and their consciences. Sir Arthur Robinson, replying, regretted the absence of Mr. J. R. Clynes at an important Cabinet meeting. Homer, he said, had constantly referred to a a physician as Μαχάων Ἀσκληπίου υἱὸς ἀμύμονος ἰητῆρος, a description which physicians were still trying to justify. Herodotus had complained that the physicians of Egypt had concentrated on one disorder each, and, to judge from the disputes which occurred between the specialist and the general practitioner, it was doubtful whether we had advanced much in this respect. He was sure, however, that the general practitioner was the foundation of the public health services, and so long as the general practitioner regarded himself not merely as a curer but as a preventer of illness he would continue to flourish. He was confident that the new post-graduate school, if properly supported, would be of the very greatest value. Dr. C. O. Hawthorne, in

proposing the health of the guests, welcomed individually the representatives of the allied and sister organisations. Sir Norman Bennett, in response, pleaded for more coöperation and less dogmatic assertion between doctor and dentist, and Sir Basil Blackett hoped that the obligation of raising funds for the centenary celebrations would not bring him under treatment for nervous disorder. Sir William Wheeler proposed the health of the chairman, and Dr. Brackenbury briefly replied.

Society of Apothecaries of London.

Presiding over a Yeomanry dinner on Nov. 18th, Lieut.-Col. C. T. Samman, the Master, proposed the health of His Majesty's Ministers and presented the honorary freedom of the Society to Mr. Arthur Greenwood, Minister of Health. Mr. Greenwood modestly maintained that His Majesty's Ministers were the best Ministers His Majesty had at the present time. As a plain man he could not pretend to understand all the large public questions arising in his office; he would be certifiable if he did. But he would not willingly change his job for any other in the world, and he would always be proud of having presided over what he regarded as the most important Department of State. The place this country would occupy in the world depended on the general level of capacity of the people, and in so far as the public health services could cut at the root of preventable disease they were doing immensely valuable work. Regardless of political views, he was willing to coöperate with anyone who could help in this work, and this would be the policy of Ministers of Health in the future as well as in the past.

After Mr. Greenwood had received the freedom, Prof. H. E. Armstrong, F.R.S., made a lively speech introducing Prof. Ernest Fourneau, of the Pasteur Institute, Paris, the recipient of the Society's gold medal for service to therapeutics. Prof. Armstrong favourably compared Fourneau's deliberate researches with those of Ehrlich and described his discovery of stovaine and other investigations as "far more thrilling and far more wonderful than any detective story." In this award the Society carried the approval of all Prof. Fourneau's scientific brethren; no better choice would have been possible. The presence of Sir Donald MacAlister and other leaders of the medical profession stimulated Prof. Armstrong to ask whether something could not be done to raise the standard of chemical training for medicine. As one who began teaching chemistry in London in 1870 he earnestly pleaded that it should be raised to a higher plane. In thanking the Society, Prof. Fourneau said he sometimes wondered whether it was not relatively easy to be noticed as a prophet in one's own country. He was, therefore, all the more grateful for this recognition from abroad. The First Secretary of the French Embassy, deputising for the French Ambassador, also thanked the Society for its honour to Fourneau and French science.

Colonel E. C. Freeman, as senior warden, hospitably proposed the toast of the guests, and responses came from Mr. Justice McCardie, the Dean of St. Paul's, and Sir William Jackson-Pope, F.R.S. Sir Henry McCardie referred to the foundation of the Society when Milton was in the nursery and Cromwell was still at school. Dean Inge spoke of the power of faith in medicine, and quoted a letter he had lately received from a lady saying: "I am praying for your death; in two other instances I have been highly successful." And following these representatives of Law and the Church, Sir William Jackson-Pope replied on behalf of what he called "the subjects that haven't mattered much since the war ended—the Army, the Navy, and science."

Glasgow University Club, London.

The annual autumn dinner of this club is to be at the Trocadero Restaurant, Piccadilly, W., on Friday, Dec. 12th, at 7.30 P.M. The Archbishop of Canterbury is to be in the chair. Any Glasgow University men who, though not members of the club, desire to attend, are requested to communicate with the hon. secretaries at 62, Harley House, N.W. 1.

Edinburgh University Club of London.

The Edinburgh University Club held its 220th dinner at the Café Royal, London, on Nov. 12th. For the first time since his election to the office of Chancellor of the University, in place of the late Lord Balfour, Sir James Barrie took the chair and presided over a large and friendly gathering. In the course of his speech he described the new undergraduates before whom he had recently given his inaugural address. To-day, he said, their dress suits were so perfectly fitting that a postage stamp in one of the pockets would cause a bulge, and he attributed this change from former times to the influence of women in the University. The health of the guests was proposed by Dr. L. F. Knuthsen with many neat allusions, and Lord Moynihan replied. Lord Aberconway represented the legal profession, giving the health of the chairman.

British Serbian Units.

The annual dinner of the British Serbian Units Branch of the British Legion and of all friends of Serbia will be held at the Grafton Hotel, Tottenham Court-road, London, W., on Saturday, Nov. 29th, at 7.15 P.M. Mr. J. R. Chappell will take the chair. Tickets may be had from Miss Marx, 24, Melcombe-court, Dorset-square, N.W. 1.

The Eastman Dental Clinic.

This clinic, adjoining the Royal Free Hospital, began work on Monday last. It has been built at the cost of Mr. George Eastman, chairman of the Eastman Kodak Company of America, and has been endowed jointly by Lord Riddell and Sir Albert Levy.

Birmingham General Hospital.

Sir Gilbert Barling, senior consulting surgeon and vice-president of Birmingham General Hospital, recently opened a new casualty department, with three wards and other extensions in that institution. Sir Gilbert stated that the hospital dealt with an average of 40,000 casualties a year. The cost has been about £45,000.

Ashford Nurses' Hostel.

Princess Helena Victoria recently opened the new nurses' hostel at Ashford Hospital, Kent, which was opened two years ago. The hospital, which in consequence of the liberation of the nurses' former quarters will now accommodate 86 patients, is a recognised training centre for nurses.

Royal United Hospital, Bath.

Mr. Aubrey Bateman, the Mayor of Bath, who has just completed his term of office, initiated a campaign to raise £90,000 for the rebuilding of the Royal United Hospital, to meet a promised donation of £10,000 by Mr. Stanley Wills, conditionally upon that sum being raised by the end of Mr. Bateman's mayoralty. The amount actually obtained by noon on Nov. 10th was £73,500, whereupon Mr. Wills at once redeemed his promise. This was his second donation of £10,000.

Fire at Sheffield Royal Hospital.

On Tuesday last week an outbreak in the basement of Sheffield Royal Hospital necessitated the removal into the open air as a precautionary measure of the patients in the casualty ward. The fire brigade arrived promptly and subdued the flames in a few minutes, and not much damage was done, but Mr. W. A. Booth, the secretary, was severely burned on the face and hands. Inspector Cornish, the second officer of the brigade, was similarly injured, and an electrician suffered from less serious burns.

A Course for Lady Almoners.

It is proposed to give a course suitable for lady almoners at Armstrong College, Newcastle-on-Tyne, and a small group of students has already been formed. It is hoped that eventually the whole of the training will be given there, thus avoiding the necessity of students coming to London for the practical part of their experience in a hospital and with a recognised social service organisation.

Central Council for Health Education.

At the third annual Health Education Conference, organised by the Council and held on Nov. 13th in the School of Tropical Medicine, Lord Riddell, who presided at the first session, gave an address entitled "Publicity in Public Health." He referred to the vast improvement in health organisation in the space of a generation, but questioned whether the social services were based on a correct philosophy. Was it sound that we spent so much money each year in caring for mentally defective persons while we restricted our expenditure on the normal child? He put forward a strong plea for sterilisation, which gave rise to lively discussion. Several speakers complained that popular health articles were refused by the lay press. Lord Riddell suggested that a better method of securing editorial notice was to make some startling expression of opinion on a subject which would be taken up by reporters with avidity. Mr. John Hall described the method he uses in popular health talks. By a combination of simple sketches and verbal mnemonics he builds up on the blackboard an astonishing series of biological pictures. Prof. H. R. Kenwood, who presided over the afternoon session, gave a résumé of the Council's coördinating function during the past year. Mr. G. H. Barker, a member of the National Union of Teachers, told of insanitary conditions in schools. Dr. A. Adam, speaking for the German Central Agency for Popular Hygiene, described the teaching of health in the schools of the Reich. The Conference was well attended by representatives of local authorities and voluntary societies. Some of the latest health films were demonstrated.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Nov. 24th.—8 P.M., ODONTOLOGY. Casual communication: Mr. J. Lewin Payne: A Case of Re-plantation and the Result after Nine Years. Paper: Dr. A. F. Hurst: The Teeth and the Stomach.
TUESDAY.—5 P.M., MEDICINE. Clinical Meeting at Guy's Hospital, S.E. Cases: Dr. A. F. Hurst: 1. Parathyroid Tumour with Osteitis Fibrosa. 2. Aplastic Anæmia of Five Years' Duration. 3. Tumour of Liver with Extreme Leucocytosis. Dr. J. J. Conybeare: 4. Infantile Hepatomegaly with Diaphragmatic Hernia. Dr. J. M. H. Campbell: 5. Rheumatic Heart Disease with Temporary Complete Heart Block. Dr. L. J. Witts: 6. Hepatic Cirrhosis with Diabetes Mellitus. Dr. A. C. Hampson: 7, 8 and 9. Multiple Hereditary Telangiectases. Dr. R. E. Smith: 10. Hour-glass Carcinoma of Stomach. Dr. E. C. Warner: 11. Familial Nystagmus. Dr. E. T. Conybeare: 12. Familial Essential Thrombocytopænia. Dr. C. F. Cosin: 13. Microcytic Anæmia after Gastro-enterostomy Cured by Iron. 14. Megalocytic Anæmia after Gastro-enterostomy Cured by Liver. Dr. R. S. Bruce-Pearson: 15. Chronic Trophœdema. Dr. H. J. Croot: 16 and 17. Erythræmia with Peripheral Vascular Changes. Other cases will be shown.
WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Papers: Dr. G. H. Edington and Dr. D. F. Cappell: Columnar-celled Adenocarcinoma Arising in Undescended Testicle of Horse, with secondary Deposits in Thorax. Dr. Nathan Raw: Transmission of Tuberculosis from Animals to Man.
THURSDAY.—8.30 P.M., UROLOGY. Clinico-Pathological Evening.
FRIDAY.—5 P.M., CHILDREN. (Cases at 4.30 P.M.) Cases will be shown. 8 P.M., EPIDEMIOLOGY. Paper: Dr. J. M. Hamill: Food as a Preventive of Disease.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Nov. 24th.—8 P.M., Clinical Evening.

ROYAL INSTITUTION, 21, Albemarle-street, W.
THURSDAY, Nov. 27th.—5.15 P.M., Mr. L. C. Martin, D.Sc.: Colour Vision (2).

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.
FRIDAY, Nov. 28th.—8.30 P.M. (at the Wellcome Museum of Medical Science, 33, Gordon-street, W.C.), Dr. S. H. Dawkes: The Application of the Synthetic Method of Teaching to Syphilis and Yaws, with demonstration of specimens, &c., to be followed by a discussion.

THE EUGENICS SOCIETY.
TUESDAY, Nov. 25th.—5.30 P.M. (at the rooms of the Linnean Society, Burlington House, W.), Mr. W. T. J. Gunn: The Heredity and Environment of our Empire Builders.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Nov. 24th to SATURDAY, Nov. 29th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W., Special M.R.C.P. Lectures at 8.30 P.M.—Tues. and Fri., Dr. W. J. Adie: Diseases of the Nervous System. Mon., at 4 P.M., Mr. E. G. Slesinger: Recent Advances in the Treatment of Toxic Goitre. Free lecture.—HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill, N.W. Demonstration on selected Medical Cases by Dr. Adolphe Abrahams on Mon., at 3 P.M. No fee for attendance.—EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E. Demonstration of Orthopædic cases by Mr. Acton Davis on Wed., at 2 P.M. No fee for attendance.—CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. Special post-graduate course. All day.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special course in medicine, surgery, and gynæcology.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Special course late evening. Demonstrations on selected cases at 5 P.M.—ST. MARK'S HOSPITAL, City-road, E.C. Special all-day course in proctology.—Further particulars from the Fellowship of Medicine.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Nov. 24th.—12 noon, Dr. Greenfield: Pathology of Cerebral Tumours. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Drug Addiction.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: Head Injuries.
WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Diseases of the Pituitary Body.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. James Collier: Acute Diseases of the Spinal Cord and Brain Stem.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Nov. 24th.—10 A.M. to 1 P.M., Surgical Wards, Genito-Urinary Operations, Skin Department. 2 P.M., Operations, Surgical Wards, Medical, Surgical, Eye and Gynæcological Out-patients.
TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clinical Demonstration (Surgical), Dental Department. 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.
WEDNESDAY.—10 A.M. to 1 P.M., Medical and Surgical Wards, Children's Medical Out-patients. 2 P.M., Gynæcological and General Operations, Medical, Surgical, and Eye Out-patients.
THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Demonstration of Fractures. 2 P.M., Operations, Medical, Surgical, and Genito-Urinary Out-patients.
FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Department, Dental Department, Clinical Demonstration (Medical). 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.
SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacterial Therapy Department, Medical Wards, Children's Medical and Surgical Out-patients.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.
TUESDAY, Nov. 25th.—5 P.M., Dr. H. W. Barber: Immunity and Anaphylaxis.
THURSDAY.—5 P.M., Dr. G. B. Dowling: Staphylococcal Infections.

LONDON SCHOOL OF TROPICAL MEDICINE AND HYGIENE (Public Health Division).
THURSDAY, Nov. 27th.—5 P.M., Dr. J. S. Owens: Atmospheric Pollution.

KING'S COLLEGE, Strand, W.C.
THURSDAY, Nov. 27th.—5 P.M., Mr. W. Robson, D.Sc.: Protein Metabolism. (Third of four lectures.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.
THURSDAY, Nov. 27th.—9 P.M., Mr. C. P. G. Wakeley: Thyroid Enlargement and Its Treatment.

UNIVERSITY COLLEGE, Gower-street, W.C.
MONDAY, Nov. 24th.—5 P.M., Mr. L. E. Bayliss, Ph.D.: Respiratory Functions of the Blood. (Third of four lectures.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Nov. 24th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C.
THURSDAY, Nov. 27th.—5 P.M., Mr. R. C. Brown: The Treatment of Disproportion.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.
WEDNESDAY, Nov. 26th.—4 P.M., Mr. T. Pomfret Kilner: Modern Reconstructive Surgery.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Nov. 26th.—4.30 P.M., Dr. David Thomson: Common Infections of the Genito-urinary Tract.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Nov. 28th.—4 P.M., Mr. Harold Kisch: Frontal Sinusitis—Diagnosis and Treatment.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.
WEDNESDAY, Nov. 26th.—4.15 P.M. (at St. John's Hospital, 49, Leicester-square, W.C.), Clinical cases and a discussion on Thallium, to be opened at 5 P.M. by Dr. Roche Lynch and followed by Dr. Graham Little, Dr. Dowling, Dr. Wigley, and others.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Nov. 25th.—3.15 P.M., Mr. Kenneth Walker: Hæmaturia.

THE CHADWICK TRUST.
FRIDAY, Nov. 28th.—5.30 P.M. (at the Royal Society of Arts, John-street, Adelphi, W.C.), Sir Robert Philip: The Outlook on Tuberculosis: Changing Orientation. (Malcolm Morris Memorial Lecture.)

INSTITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, Nov. 26th.—3.30 P.M., Dr. W. F. Christie: The Prevention of Obesity.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 26th.—4 P.M., Mr. L. Ward: The Prevention of Accidents in Workshops and Factories.
THURSDAY.—4 P.M., Mr. Harold Chapple: Contraceptive Responsibilities of the Medical Practitioner.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.
FRIDAY, Nov. 28th.—3.30 P.M. (at the Royal Infirmary), Dr. Brockman: Syphilis of the Alimentary Tract.

BRITISH EMPIRE CANCER CAMPAIGN POST-GRADUATE LECTURES ON CANCER (YORKSHIRE COUNCIL).
WEDNESDAY, Nov. 26th.—3.30 P.M. (in the Halifax Infirmary), Prof. W. Beckwith Whitehouse: Uterine Hæmorrhage, with Special Reference to Malignant Disease.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSES.

TUESDAY, Nov. 25th.—4.15 P.M., Dr. F. E. Tylecote: Low Blood Pressure.

FRIDAY.—4.15 P.M., Dr. Blair: Mental Defect.

ANCOATS HOSPITAL, Ancoats, Manchester.

THURSDAY, Nov. 27th.—11 A.M., Dr. E. W. Twining: Clinical Demonstration. 4.15 P.M., Dr. Arnold Renshaw: Systematic Pathological Investigation of a Case of Rheumatoid Arthritis.

Appointments

HEATH, W. E., M.B., B.S. Lond., D.O. Oxon., has been appointed Hon. Ophthalmic Surgeon to the Kent County Ophthalmic and Aural Hospital, Maidstone.

MASSIE, G., M.S. Lond., F.R.C.S. Eng., Asst. Surgeon, Orthopædic Department, Guy's Hospital.

OWENS, JAMES, L.R.C.S.I., Surgeon to Mercer's Hospital, Dublin.

RAPER, J., M.D. Manitoba, Medical College, Winnipeg, Man., Anæsthetist, The Infirmary and Dispensary, Warrington, Lancs.

Certifying Surgeons under the Factory and Workshop Acts: EVANS, E., L.R.C.P. Lond., M.R.C.S. (Llanybyther, Carmarthen); FORGIE, A. D., M.B., Ch.B. Aberd. (Stonehaven, Kincardine)

London County Council: KING, E. J. (Miss), M.B., B.S. Lond., L.R.C.P., Asst. M.O.; Dulwich Hospital. JENNINGS, C. M., F.R.C.S. Eng., L.R.C.P. Lond., Asst. M.O., Fulham Hospital. JACOBS, P., M.B., Ch.B. Glasg., Asst. M.O., Hammersmith Hospital. FISHER, H. M., M.B., B.S., Asst. M.O., St. Mary Abbots Hospital, Kensington. THOMPSON, A. R., M.B., B.S., and WESTWATER, J. S., M.B., Ch.B. Edin., Junr. Asst. M.O.'s, Park Hospital. BOWTELL, A. R., M.A., B.Ch., Asst. M.O., St. Charles Hospital, Marylebone. KNIGHT, S., L.R.C.P. Lond., M.R.C.S., Asst. M.O., St. Peter's Hospital, Vallance-road, E.1. ROANTREE, W. B., M.B., B.Ch. Dubl., Asst. M.O., Hackney Hospital. YOUNG, B. A., M.B., B.S., Asst. M.O., Archway Hospital, Highgate. THOMAS, T. P., M.B., Ch.B. Edin., Asst. M.O., St. Olave's Hospital, Rotherhithe. SIMMONS, J. H., M.B., B.S. Lond., Asst. M.O., Downs Hospital for Children. IVE, C., M.B., B.S. Lond., Junr. M.O., King George V. Sanatorium, near Godalming. SHAW, P. H. S. (Miss), M.B., B.S. Lond., D.P.H., St. Benedict's Hospital, Tooting, S.W.

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Mental Hospital.—Jun. Asst. P. £300.

Aberdeen Royal Infirmary.—Jun. Asst. Surg. for Ear, Nose, and Throat Dept.

Albert Dock Hospital, Connaught-road, E.—Asst. Surgeon.

Bradford Royal Eye and Ear Hospital.—Jun. H.S. £150.

Birmingham General Hospital.—2 Res. Surg. Reg. to Special Depts. £100–£120—£140.

Bolton Infirmary and Dispensary.—Two H.S.'s. Each £150. Also Cas. O. At rate of £150.

Bury St. Edmunds, West Suffolk General Hospital.—Jun. Res. M.O. £150.

Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.

Canterbury, Kent and Canterbury Hospital.—H.S. At rate of £125.

Cape Town University.—Assistant Anatomist. £750.

Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.

Cheshire Joint Sanatorium, Market Drayton, Salop.—H.P. £250.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.

Coventry and Warwickshire Hospital.—Res. Asst. H.S. £125.

Croydon General Hospital.—Hon. M.O. to Diseases of Children. Also Res. M.O. £200.

Dewsbury and District General Infirmary.—Sen. H.S. £200.

Downpatrick, N. Ireland, Down Mental Hospital.—Jun. Asst. M.O. £300.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.

Golden-square Throat, Nose, and Ear Hospital, W.—Hon. Reg. Also Hon. Clin. Asst.

Hampshire County Council.—Asst. County M.O. £600.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.P. and H.S. Each at rate of £100.

Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150. Also H.S. and H.P. Each at rate of £100.

Hull Royal Infirmary.—Asst. H.P. At rate of £130.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.

Leeds, Killingbeck Tuberculosis Sanatorium.—Asst. Res. M.O. £250.

Lincolnshire (Kesteven) C.C.—Asst. County M.O.H. £500.

Liverpool, Royal Babies' Hospital, Woolton.—Res. M.O. At rate of £90.

Liverpool, Royal Southern Hospital.—Hon. Dental Surgeon.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. Also H.P. At rate of £120 and £100 respectively.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.

Manchester, Ancoats Hospital.—Part-time Med. Reg. and Surg. Reg. Orthopædic H.S. All at rate of £100.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Sen. Res. M.O. At rate of £125.

Manchester City, Abergele Sanatorium.—Med. Supt. £900.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Metropolitan Hospital, Kingsland-road, E.—Asst. M.O. to X Ray and Electrical Dept.

Miller General Hospital, Greenwich-road, S.E.—H.P. and H.S. Each at rate of £125. Also Out-patient Officer. At rate of £150.

Monmouthshire County Council.—Two Asst. M.O.'s. Each £500.

National Hospital, Queen-square.—H.P. £150.

Nelson Hospital, Merton, S.W.—Res. M.O. At rate of £100.

Newcastle-upon-Tyne Royal Victoria Infirmary.—H.S. to Skin and Venereal Dept. At rate of £50.

New Zealand, Hawkes Bay Hospital, Napier.—Pathologist. £750.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Nottingham City Infirmary, Hucknall-road.—Two M.O.'s. Each £350.

Plymouth, South Devon and East Cornwall Hospital.—H.P. Also H.S. to Casualty and Special Dept. At rate of £120 and £100 respectively.

Prince of Wales's General Hospital, N.—Hon. Clin. Assts. to Various Departments.

Princess Louise Kensington Hospital for Children, St. Quintin avenue, N. Kensington.—H.S. At rate of £100.

Queen's Hospital for Children, Hackney-road, E.—H.P. At rate of £100.

Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O., H.S.'s, H.P.'s, &c. At rate of £200, £150, and £120 respectively.

Richmond, Surrey, &c., Joint Isolation Hospital Committee Hospital, Mogden.—Res. M.O. £400.

Royal National Orthopædic Hospital, Great Portland-street, W.—Hon. Asst. Surg.

Sheffield, Children's Hospital. Third Res. M.O. £100.

Sheffield Royal Hospital.—Ophth. H.S. Also Res. Anæsthetist. Each at rate of £80.

Sheffield Royal Infirmary.—Ophth. H.S. £80–£100.

Somerset County Council, Sandhill Park, Bishop's Lydeard, nr Taunton.—Med. Supt. £850.

Southport General Infirmary.—Jun. H.S., &c. £150.

St. George's Hospital, S.W.—Sen. and two Anæsthetists.

Sunderland, Durham County and Sunderland Eye Infirmary.—H.S. £350.

Todmorden Borough.—M.O.H. and School M.O. £800.

University College Hospital, W.C.—Hon. Clin. Asst. Also Hon. First Asst. to Special Depts.

Warwick, Hertford Hill, King Edward VII Memorial Sanatorium.—Jun. Asst. M.O. At rate of £200.

West Bromwich, Hallam Hospital.—Res. H.P. £250.

West London Hospital, Hammersmith-road, W.—Non-Res. Cas. O. £250. Also H.P., H.S., and Aural and Ophth. H.S. Each at rate of £100.

Weston-super-Mare, General Hospital.—Res. H.S. At rate of £150.

West Riding Mental Hospital, Starthos Hall, Kirkburton.—Asst. M.O. £400.

Wigan Royal Infirmary.—Res. Med. and Surg. Officer and Registrar. £250.

Willesden General Hospital, N.W.—Hon. Clin. Asst. to Surgical Out-patient Dept.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. At rate of £100. Also Part-time Pathologist. £300.

Wrexham and East Denbighshire War Memorial Hospital.—Hon. Surgeon to Ear, Nose, and Throat Dept.

Births, Marriages, and Deaths

BIRTHS.

RIDDELL.—On Nov. 16th, the wife of Dr. Renton Riddell (E. A. Shuttleworth, M.B.), of Baldock, Herts., of a son.

TERRY.—At Nyaunghla, Upper Burma, on Oct. 7th, 1930, to Helen Margaret, wife of Dr. Gordon Stuart Terry—a son.

DEATHS.

FRAZER.—On Nov. 15th, Ewan Richards Frazer, M.B., B.Ch.Oxon., of Lennox-gardens, London, and late of Frampost, East Grinstead.

STOKES.—On Nov. 13th, at Bedford, Alexander Haldane Stokes, Lieut.-Col., Retired, late A.M.S., aged 88.

WARD.—On Nov. 10th, at Dynevor-road, Richmond, Walter Alfred Ward, M.R.C.S., in his 83rd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

DRIFFIELD COTTAGE HOSPITAL.—The urban council of Driffield is about to erect a municipal cottage hosptal, in addition to the already existing hospital. The cost will be £8000, and there will be 18 beds in two six-bed wards, two single and two double private wards, one of which can be used for children.

NOTES, COMMENTS, AND ABSTRACTS

TRACHOMA IN IRELAND.*

By Francis S. Lavery, M.B., D.O.M.S.,
MONTGOMERY LECTURER IN OPHTHALMOLOGY (1930), UNIVERSITY OF DUBLIN.

It is impossible to give even approximate figures of the incidence of trachoma in Ireland as there is no source from which they might be compiled. Of all the countries of the world whose inhabitants are subject to trachoma, this country is the only one where no official effort has been made to check its spread and ravages.

I started by looking through the case sheets of the patients who had attended at the Royal Victoria Hospital, Dublin, for the ten years 1919–1928. The numbers of new trachoma patients who presented themselves during these years were as follows:—

Year.	Cases.	Year.	Cases.	Year.	Cases.
1919	123	1923	115	1927	70
1920	118	1924	102	1928	98
1921	81	1925	117		
1922	130	1926	127		

The figures maintain a fairly level average over these years and it would appear that the disease has now reached a sort of equilibrium, neither increasing nor decreasing. Of course, a larger number of trachoma patients were treated each year, as each patient has to attend more or less regularly for over a year and they keep returning from time to time. These figures may not appear alarming, but when we consider the disability produced in these unfortunate persons we shall be appalled by the number who are rendered incapable of doing even a reasonable amount of work.

Out of these 1081 trachoma patients I only find the visual acuity recorded of 478. We must therefore take these 478 as being representative of the whole 1081. It seems to me probable that the reason why vision was not taken in a larger number of the unrecorded cases was that the state of the eyes made it difficult to do so. Of these 478, 114 had vision below 3/60, which is the standard required by the Blind Pensions Act. That means that 23·8 per cent. are unable to do work for which eyesight is required. In addition 137 (or 29·6 per cent.) have less than the blind pensions standard in one eye. This leaves only 47·6 per cent. with vision above 3/60 in both eyes. Vision above 6/36 was very rare indeed.

Prevalence in Institutions.

There is little room for doubt that the occurrence of trachoma has declined owing to improved housing and sanitation, and the generally raised standard of living, but this diminution applies only to the public at large and not to our institutions where the disease is still very prevalent. When I first started to inspect these I was amazed at the number of cases of trachoma I discovered which had previously been undiagnosed and which presented no symptoms until sought for. I have since ascertained that this has been the experience of other investigators. The fact is that the greater number of those attacked in their earliest years escape clinical observation and are not examined by an oculist until a complication arises. It would appear that some secondary infection is required before trachoma makes itself manifest. One investigator writes:—

> "Between the children infected and those who were not we did not notice any exterior difference either at the edges of the eyelids or at the *palpebral opening*. Turn over the upper eyelid, however, and the difference appears immediately."

It is, therefore, apparent that only by some system of methodical and regular inspection in our institutes can trachoma be detected.

In passing, I note that the age of infection appears to be higher among the institutional cases than among those in ordinary life where the father and mother are the source of infection. It is generally accepted that parents pass it on to their elder children in infancy, and later, when the parents have become more or less non-infective, the disease is passed on by the elder children to the younger.

In the course of my investigations I visited in all ten institutions for boys and girls, where I examined 917 subjects. I compare two orphanages for the sake of illustrating my point about the age of infection. In a boys' orphanage where the ages ranged from 4 to 8 years the trachoma percentage was 11·5 and even that was confined to the elder ones, whilst in a girls' orphanage where the ages ran from 4 to 18 the percentage was 20·5. The average age among the infected girls was 13 and none of the very young children was infected. This orphanage struck me as being very well run, but what are those in charge to do? They cannot isolate the infected girls, and they have no Swanley to which they can send them as in England. I take this latter orphanage to prove the necessity for inspection. Among the 117 girls examined 67 were free from external eye disease. There were ten cases of external eye disease other than trachoma or follicular conjunctivitis, 12 cases were being treated for trachoma, and above this I found 12 cases of previously undiagnosed trachoma and treatment of these for over one year has confirmed my diagnosis of that disease. A few of the cases I had put down as follicular conjunctivitis have also turned out to be trachoma.

Here are still more alarming figures from an institution in County Cork. Out of a total of 124 girls examined 31 had definite trachoma and 20 were marked as suspicious; that is, 25 per cent. of the girls had well-marked trachoma. I assisted Miss Euphan Maxwell in investigating the causes of blindness among the inmates of a blind asylum where it was impossible to make a detailed examination. Of 83 cases examined 15 (or 18 per cent.) owed their blindness to trachoma, no other cause claiming so high a figure. Through the courtesy of Dr. M. O'Leary I was enabled to inspect a number of Dublin schools, and compared with the above depressing figures it is somewhat consoling to note that out of 324 school-children examined the trachoma percentage was 1·8, and some of these schools were in areas where one might expect to find trachoma at its worst.

An Anti-trachoma Campaign.

There are three distinct ends in the anti-trachoma struggle that we can propose to ourselves:—

1. To prevent new infections by instituting a series of prophylactic measures in the family, in the schools, and in the institutions.
2. To seek out cases of latent trachoma and care for them from the first appearance of the malady.
3. To treat the trachomatous who present complications with a view to curing them of their trachoma as well as of the maladies superimposed.

When we consider that in our institutions throughout the country the infected and the uninfected are all herded together and the latter are exposed daily to danger of infection we must feel convinced of the necessity for action. In most of the institutions nothing is being done to protect the uninfected and very little towards treatment of the infected, the reason for this being largely that those in charge are completely ignorant on the subject. It is difficult to formulate a scheme for combating the evil. A great number of countries where trachoma is prevalent have adopted measures to combat the evil, because it is not only an affliction to the individual sufferers

* The Montgomery Lecture will appear in full in the January number of the Irish Journal of Medical Science.

but also a source of economic loss to the community. Families fall into misery as soon as the malady enters their dwellings, the breadwinner being forced to remain inactive for prolonged periods.

The formulation of a scheme of prophylactic measures can best be done by studying the methods employed in other countries, above all in those which have almost entirely rid themselves of the scourge. These methods may be divided into two categories: general measures and special measures. Among the first we may put the improvement of housing and a raising of the general standard of living. The latter is of great importance, as trachoma is essentially the malady of the indigent, for indigence brings want of cleanliness both in person and dwelling. In France, Russia, and Poland trachoma is a notifiable disease, but here we are faced with the difficulty that it requires a skilled ophthalmic surgeon to diagnose it with any degree of certainty in its early stages. There is also the danger of its being overdiagnosed and harmful caustic treatment applied, as frequently happens in India. In Egypt and Russia there are travelling hospitals for the purpose of teaching the local doctors as much as for the purpose of treating the disease. Countries such as Prussia, Hungary, and Czecho-Slovakia have extensive courses of instruction for the parish doctors. Notification is not much good unless treatment is made compulsory. This is done in China, and is forced on migratory labourers and prisoners in Czecho-Slovakia. In Turkey no one is allowed to work in a public place with uncured trachoma. Hungary, at the outset of the war, formed a trachoma regiment for the purpose of preventing its spread throughout the army and so that all cases might be collected together for treatment, and precautionary measures were to have been taken when demobilisation was being effected. This plan was knocked on the head by the revolution and collapse of the Central Powers, with the result that there was a terrible increase in trachoma in parts of Hungary after the war. From that country comes a proposal for the formation of industrial colonies for the trachomatous, also the suggested State support of families of patients undergoing treatment.

An English Model.

The methods adopted in England seem to me to serve as a more suitable model for our imitation than those of continental countries where conditions are so different from ours. In England the disease is steadily diminishing. Compare the figures of registered cases in the schools under the late Metropolitan Asylums Board of London. In 1912 there were 153 cases registered. Each subsequent year shows a reduction in the number of registrations and in 1920 the number was 26. The London County Council is to be congratulated on the success achieved in the area under its control. An ophthalmic school was founded near Swanley. This school takes in all cases of infectious eye disease and lately interstitial keratitis has been included because of the beneficial effects of fresh air and sunlight on that disease. To this school are sent all the cases of infectious eye disease that are recommended for treatment by the medical officers in the London area. Through the courtesy of Mr. M. S. Mayou I have had an opportunity of visiting this school. It is divided into a number of units, each consisting of three separate cottages. In the central one resides the mother or sister in charge. Here all the cooking is done and meals taken, and here also is the treatment room. The children live in this and the other two cottages. The trachoma unit is completely separate from the other cottages and is surrounded by a double fence. I asked did not the patients feel hurt by this segregation and was told that on the contrary they consider themselves the nobility of the place as naturally they are the oldest inhabitants. They attend separate classes and never come across the other inmates. The children are usually very happy at Swanley, and on more than one occasion have been detected trying to reinfect themselves from the others to avoid being discharged as cured.

I am satisfied that the only satisfactory method of treating trachoma is in a separate institute. The present method of a patient having to attend a hospital three times a week over a prolonged period of time is unsatisfactory. It interferes with the education of the school-children and no institute could afford the expense involved. The effect of the present system is that patients only attend spasmodically, when their eyes are giving them pain. Things can no longer be allowed to drift. At the orphanage where I inspected 117 girls and found 24 definite and some doubtful cases of trachoma I have during the last year and a half inspected each new inmate, placing those showing trachoma immediately under treatment. On re-inspecting this orphanage recently I found 11 new victims and 13 cases in which the diagnosis is still doubtful. There can be little doubt that these children succumbed because of their proximity to those already infected.

Application to Ireland.

If the establishment of an ophthalmic school is considered too big an undertaking we might set aside two of our existing orphanages, one for boys and one for girls, to which the infected could be transferred from other orphanages in Ireland. The achievement of this plan would go a long way towards the eradication of what I may call institutional trachoma but would not tend to diminish materially the disease outside. All my investigations among school-children have been carried out in Dublin, but I am informed by doctors practising on the Western seaboard, where the standard of living is very low, that trachoma is very prevalent there. At the international trachoma conference in Geneva attention was drawn to the fact that as one of the best methods in the struggle against trachoma is to attack it in early infancy the necessity of a precise diagnosis becomes evident. In the City of Dublin a system of medical examination has been established in the schools but only on a voluntary basis. While the public mind may not yet be prepared to accept the compulsory system the following plan might eventually lead to it. Extend the medical examination to the whole State and add a special examination by a qualified oculist. Direct the oculist (and this is the important point) in the case of the discovery of any infectious eye complaint to endeavour to induce the family of the sufferer to submit to an examination. Thus the root of the evil would be reached and the younger members of the family would come under treatment at an age when they could be readily curable. Treatment could then be properly carried out by a skilled nurse acting under the direction of an oculist, with only periodical inspection by him. In one of the girls' orphanages the sister in charge has been able to carry out directions, and with monthly visits by me satisfactory progress is being made.

NOISE AND ITS MEASUREMENT.

THE universal problem of noise is at its worst, perhaps, in New York, where it has been approached scientifically and thoroughly. A brochure called City Noise,[1] publishes the report of the commission which has been investigating it. A year ago a travelling noise laboratory began a cruise of the city to measure the intensity of sound in various areas. Two devices were used: a measure of deafening effect and a "noise meter" that registered intensity directly through a microphone. The masking effect of any given noise was determined by the intensity necessary to make a known tone audible above it. The amount of noise is the difference between this intensity and the intensity required in a quiet place. This indirect method, depending on the human ear, was a useful addition to and check on direct measure-

[1] Noise Abatement Commission, Department of Health, City of New York. 1930. Pp. 308.

ments. The unit of noise—the decibel—is approximately the smallest change in sound which the human ear can detect; it is not an absolute unit, but a symbol for the ratio of intensities. In general, the numbers of decibels measuring the difference between two sounds is ten times the common logarithm of the intensity ratio. An ordinary conversation has a loudness of about 60 decibels—that is to say, 10^6 times the least intensity the normal ear can hear. A total of about 10,000 observations was made, and in several places the aggregate noise was analysed by means of band-pass filters.

The results showed that riveting and blasting were the worst noises of New York, measuring 96 or 97 decibels, but the average noise of a subway express passing a station was 94 decibels, while a loud-speaker at its noisiest accounted for 79—an intensity 100,000,000 times greater than the smallest distinguishable sound. The exhaust of a motor lorry accounted for 77 decibels, and the automobile horn for 71. At these levels, conversation is difficult, study impossible, and normal sleep almost out of the question. The average noise level inside rooms in residential districts was found to be 31 decibels, and approximately half the noise came from outside the house. Under normal traffic conditions a sound had to have a loudness of 50–55 decibels to be heard, and in main streets this might rise to 75 decibels. An amusing comparison with sounds from the Zoological Gardens showed that while a roaring lion (87 decibels) would be audible in the streets for 20 or 30 feet, a Bengal tiger (75·5 decibels) might roar indefinitely without attracting the attention of passers-by.

Great improvements have been made by padding turnstiles at the stations and replacing traffic-police whistles by lights. A series of tests was made on standard motor-horns, and it was found that an adequate warning sound need not be startling or nerve-racking, and that the average horn was a great deal louder than necessary. Some of the horns could be heard ten miles off. Many horns were found to be unpleasant because of high notes, which could be filtered off. The only way to deal with construction and demolition noises seems to be prohibition during hours of rest and the provision of adequate mufflers on the intakes of air compressors. The Commission recommended a "noise squad" as part of the City Health Department, and an extensive educational campaign, for they realise that there is no quick solution of the noise problem; the coöperation of every manufacturer, employer, and employee is needed before any appreciable improvement can be effected.

INSTITUTIONAL DIETETICS.

RECENT intensive laboratory studies of the principles of nutrition and their application to human dietaries have demonstrated clearly the health-promoting value of specific foods and accessory food factors. The science of dietetics, if there be one at the present time, no longer rests on a basis of mere energy exchanges. The application of the modern knowledge of nutrition to the bulk feeding of human beings is frequently neglected even in institutions which cater for the young, the sick, and the infirm. We deplore the statement in the preliminary section of a small manual devoted to institutional dietetics[1] that little definite is known about the vitamins, and that an ideal food is one in which the proportion of carbohydrate to protein is great. An opportunity has been missed of attempting to improve the standard of nutrition of the considerable sections of the community that are regularly fed in institutions. The main contents of the book, however, are recipes which should prove valuable to housekeepers who cater for large numbers.

BIRTH CONTROL CLINICS.

A MEETING of medical officers engaged in teaching contraceptive methods recently brought to light some important observations. The meeting took place on Oct. 10th, at the British Medical Association House, and was attended by medical officers of the birth control clinics that are affiliated to the Society for the Provision of Birth Control Clinics. There was also present a representative of the Mothers' Clinic, founded by Mrs. Marie Stopes, D.Sc. Answers were brought to a questionaire that had previously been circulated, relating to failures of contraceptive methods, pathological conditions, and hæmorrhage noted in patients who had used contraceptive methods for six months or longer, the pros and cons of douching, the kinds and average sizes of occlusive pessaries used, and the complaints made by husbands regarding the appliances used by women. The questionaires were answered with varying degrees of thoroughness by the different centres. Thirteen clinics were represented, but of these only nine produced figures that justified comparison. By these nine clinics (Aberdeen, Birmingham, Cambridge, East London, Newcastle, North Kensington, Manchester, Oxford, and Walworth) 6322 patients had been followed up, and their experiences are summarised in the following figures. There had been 685 failures among this total, but of these only 95 were unaccountable—i.e., occurred in cases where the prescribed technique had been conscientiously carried out. The remaining 590 failures were attributable to known causes, such as incomplete following out of instructions, lapses from continuous use of the method, deterioration or faulty appliance, or other causes. In addition to this series of 685, there was another group of 267 women who found the method taught them impracticable for various reasons. Such were æsthetic dislike, discomfort caused either to husband or wife, or other causes. Among the difficulties of the technique which is prescribed in the majority of cases (a combination of Dutch pessary, lactic acid ointment, and douche), first place must probably be assigned to douching, which presents difficulties in many homes in which there is little privacy and inadequate facilities for obtaining warm water at short notice. For these reasons the medical officers of the North Kensington Clinic no longer advise the douche, and have substituted in its place the use of a quinine and urea hydrochloride pellet as manufactured by Messrs. Parke, Davis and Co., for producing corneal anæsthesia. This is placed in the vagina above (i.e., on the cervical side of) the occlusive pessary. It is too soon, however, to say how this technique compared with that in which the use of a douche forms a part.

A notable fact that arose from this investigation was the complete absence of harmful sequelæ that attended the proper carrying out of the instructions. Among the 6322 women here reported the only case in which a pathological condition observed was that of a woman who attended the Rotherham Clinic; but this woman had been wearing her pessary continuously day and night regardless of whether there was any need for it.

There were only 50 complaints by husbands in this series. They related mainly to the fact that the anterior rim of the pessary was felt and that the lactic acid irritated the penis. It is hoped that this will be the first of an annual series of such doctors' conferences at which the year's results will be impartially summarised and presented.

THERMEGA ELECTRIC BLANKETS.

IN the notes on the London Medical Exhibition published on Nov. 8th last we said "the blankets are made to suit any voltage from 50 to 250 with adjustment." The Company inform us that their appliances are suitable for any voltage from 100–250 without adjustment and that "blankets or pads for 50 volts have to be made specially."

DEATH-BEARING FISH.

THE perils of bathing are not confined to shark-infested waters, and Mr. David Grieg's brief paper on thanatophoric fish [1] gives further support to those who distrust the sea and all its works. The larger weever, the smaller weever, and, according to some, the sand-weever, are to be found, he tells us, in British waters, and like the flounder prefer to bury themselves in the wet sands of the shallows. It appears, however, that injuries are rarely received through the bare skin of the foot, but usually fall to the lot of those who handle these fishes in unwary curiosity. The armature of the weever consists of five or six grooved spines upon the anterior dorsal fin, enclosed in connective tissue and sharply pointed. Glands are present in the grooves which secrete a transparent, acid fluid containing an alkaloid which has a selective action on nervous tissue. When the spine is driven into the flesh the integument yields to pressure and is thrust back towards the base, while the poison flows down the groove into the wound. Distressing symptoms supervene within a few minutes, beginning with acute pain and itching at the site of inoculation; as the pain spreads up the limb it becomes unbearably intense, there is respiratory embarrassment and sweating, noises in the ears, impairment of hearing, flashes of light before the eyes, intermittent pulse, and finally, delirium, which may end in convulsions and death. Even if recovery takes place after many hours of pain, improvement is slow and malaise may persist for months. Mr. Grieg thinks a case recorded last year by Schulman and Ravier in *Progrès Médical* was doubtful as an example of poisoning by thanatophoric fish. The symptoms described by these observers included retention of urine and paresis of the legs, which progressed into an ascending paralysis and led to death from asphyxia. In spite of his vivid description of the symptoms usually observed, Mr. Grieg offers no suggestions for the first-aid or subsequent treatment of the patient, whom he abandons in convulsions on the beach. Various empirical remedies, including potassium permanganate, were detailed in a paper on Fishermen's Diseases by Dr. H. Muir Evans, of Lowestoft, reported in THE LANCET, 1921, i., 517.

THE UNITED FRUIT COMPANY'S MEDICAL SERVICE.

THE United Fruit Company maintains hospitals, hospital dispensaries, and field dispensaries in Cuba, Colombia, Costa Rica, Honduras, Guatemala, and Jamaica. An idea of the magnitude of their medical services can be gathered from the fact that during the year some 27,000 patients were admitted to their hospitals, and 360,000 treatments were given at their dispensaries. The eighteenth annual report of the Company's medical department contains many original articles, as well as statistical information dealing with the general work of the institutions concerned. Especially interesting are the papers describing methods for the treatment and prevention of malaria. The use of plasmochin as well as quinine during or immediately after the acute attack is strongly advocated. Evidence is brought forward to show that small doses of plasmochin render subtertian gametocytes, which may be resistant to quinine, non-infectious for mosquitoes. Not only is there less likelihood of relapse when plasmochin is given as well as quinine, but there is less chance of spread of infection among the mosquitoes of the districts to which the patients repair on leaving hospital. Cases of food-deficiency diseases are reported, particularly beri-beri and night-blindness; the latter occurred among railway labourers, and was cured in from seven to ten days by a generous diet, including milk and cod-liver oil. The excellence of the report of this department obviously reflects the efficiency of the medical service rendered to the populations of the districts in which the company's interests lie.

WHEAT, FLOUR, AND BREAD.

THE late Prof. Harry Snyder was, for the first half of his career, in charge of the departments of agricultural chemistry and soils in the University of Minnesota. He afterwards joined the staff of a milling company and devoted his time to investigating agricultural, nutritional, and æsthetic problems connected with the production and consumption of bread. A selection of the numerous papers which he published in his lifetime is now collected in book form.[1] The subjects dealt with range from the selection of suitable wheats for cultivation to the nutritive values of various types of flour. From a medical point of view his discussion of the relative nutritive values of white and wholemeal flour is of particular interest. The production of white rather than of wholemeal flour is urged most strongly, largely on the grounds of economy, in that the waste of nutrient material following the ingestion of bran and offal by the human being can be avoided by feeding these by-products to farm animals. Technical problems dealing with modern methods of milling and grading flour are presented lucidly in a style which should appeal to the reader with no previous knowledge of the subject.

MORTALITY FROM GALL-STONES.

THE Metropolitan Life Insurance Company of New York has analysed the deaths per 100,000 of its policy-holders from gall-stones over a period of 20 years, with some interesting results. First of all it may be noted that there has been no recent improvement in the mortality from this condition, which agrees with the general results obtained from the United States Registration Area. The death-rate in the rural regions is about one-half that of the cities, namely 2·5 against 4 to 5—a difference which may be due to increased facilities for accurate diagnosis in the case of the cities. The variation as between the sexes comes out very strongly in these figures. It has, of course, always been recognised that gall-stones are more frequent among females than males, but in this analysis at various ages the female death-rate is shown to be nearly six times the male (2·3 against 0·4) in the group of 25 to 34 years, and four times (5·9 against 1·4) in the group 35 to 44 years. The actual relative incidence of gall-stones in the two sexes is usually considered to be about 3 to 1; what these American figures go to prove is that gall-stones are the primary cause of death more often in the female. The figures, unfortunately, do not enable us to decide whether gall-stone incidence is disproportionately high, as has been believed, among women who have borne children. Until the results of the 1930 census are made known, it is not possible to determine what in the United States is the proportion of mothers in the female population.

THE METABOLISM OF ACIDS AND BASES.

IN the Leyden lecture for 1930[2] Prof. A. Magnus-Levy deals with disturbances of the metabolism of acids and bases. He does not consider the acid-base balance nor hydrogen-ion concentration, ideas which he holds to be obscure and confusing. As far as it goes the treatment of the subject is thorough, but owing to the author's self-imposed limits most practical points have to be left unexplained. It would have been more satisfactory if Prof. Magnus-Levy had expanded his lecture before publishing it in book form.

GRENFELL MISSION HOSPITAL.—It is reported that Sir Wilfred Grenfell's Battle Harbour Hospital on the coast of Labrador has been completely destroyed by fire. Sir Wilfred was lecturing in Ireland at the time.

ADDRESSES AND ORIGINAL ARTICLES

OCULAR MUSCLES, MOVEMENTS AND JUDGMENTS.

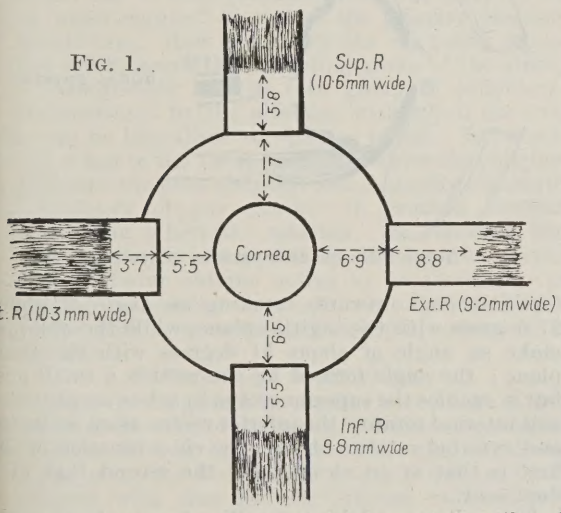
The Bradshaw Lecture delivered before the Royal College of Surgeons of England on Nov. 13th, 1930,

BY J. HERBERT FISHER, M.B., B.S. LOND.,

FELLOW AND MEMBER OF COUNCIL OF THE COLLEGE; CONSULTING OPHTHALMIC SURGEON TO ST. THOMAS'S HOSPITAL; CONSULTING SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL.

FOR the purpose I have in view it is hardly necessary to describe the extra-ocular muscles in anatomical detail. As far as their origin is concerned it is sufficient to remember that each of the four recti muscles arises at the apex of the orbit from the tendinous zonule of Zinn, which surrounds the optic foramen and crosses the inner and lower part of the superior orbital fissure. The superior oblique arises in the same immediate neighbourhood; its rounded fleshy belly passes forward in the angle formed by the roof and inner wall of the orbit to a tendon which plays in the trochlea attached to the orbital roof just behind the internal angular process; by means of its pulley the tendon makes a bend to pass downwards, backwards, and outwards at an angle of about 51 degrees with the sagittal axis and so reaches its insertion on the postero-external quadrant of the eyeball. The inferior oblique arises in a small depression in the

FIG. 1.

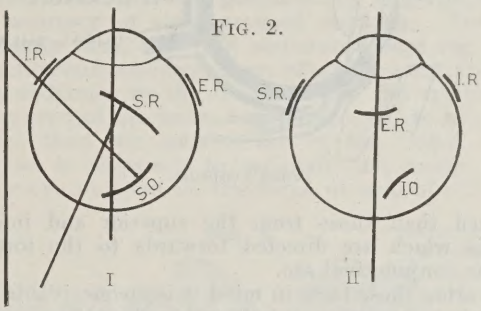


Scheme to show insertions of recti muscles with breadth and length of their tendons (after Whitnall).

orbital floor, immediately external to the naso-lacrymal groove; after passing beneath the globe and inferior rectus muscle it ascends to its insertion on the postero-external quadrant of the eyeball rather posterior to the attachment of the superior oblique, and therefore somewhat nearer to the optic nerve. The inferior oblique in its whole course makes the same angle with the inner wall of the orbit as the reflected tendon of the superior oblique and in lower vertebrates the superior oblique arises, like the inferior oblique, just behind the orbital outlet and thence passes directly to its insertion; the two muscles in such animals are much more obviously comparable than in the human subject they at first appear to be.

The outer wall of the orbit makes an angle of about 45 degrees with the inner wall, and in the primary position of the eyes at rest the visual axes are parallel to each other and directed straight forwards in the sagittal plane in alignment with the inner orbital walls. The combined length of its fleshy belly and tendon of insertion is approximately the same for each of the four recti muscles, but there are considerable differences in the length of their tendons; the fleshy bellies therefore differ not only in width but also in length and contractile capacity; in full contraction the muscular portion of each rectus shortens by about 25 per cent. The tendons, moreover, are attached

FIG. 2.



Insertion of ocular muscles (I) seen from above, and (II) seen from outer side (after Merkel).

at varying distances behind the sclerocorneal margin and lie in an irregular spiral (Figs. 1 and 2).

Fig. 1 applies to the recti muscles, and indicates the points in regard to their tendons and sites of insertion to which I have referred. Fig. 2 is introduced more particularly to show the attachments of the two obliques, and it will be observed that in the normal eye the posterior end of the superior oblique line of insertion transgresses on to the postero-internal segment of the globe.

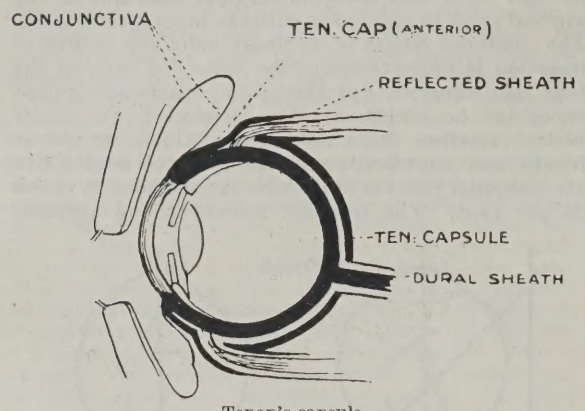
TENON'S CAPSULE.

Figs. 3 and 4 represent Tenon's capsule diagrammatically. The conception that in its movements the eyeball rotates within the cup formed by Tenon's capsule is of ancient date and difficult to eradicate from the mind; a very slight consideration of the anatomical arrangement of the capsule, however, shows it to be erroneous.

It is now certain that Tenon's capsule has no serous, or visceral, layer; it is a fibro-elastic membrane more dense posteriorly where it passes into continuity with the fibrous dural sheath of the optic nerve; anteriorly it is thinner and blends intimately with the deep surface of the ocular conjunctiva, and with it is attached to the globe at the sclerocorneal junction in the whole circumference of the limbus. Everywhere it is adherent by strands of loose episcleral tissue to the surface of the sclerotic coat. It is perforated posteriorly by the posterior ciliary vessels and nerves on their way to penetrate the sclerotic around the porus opticus; at the equator the venæ vorticosæ emerge through it, while in the ciliary area the anterior ciliary arteries and veins traverse it. Moreover, where the capsule is penetrated by the tendons of the extra-ocular muscles it sends a sheath along each tendon, which sheath passes into continuity with the perimysium; in the case of the superior oblique the sheath is traceable as far as the trochlea; off the sheath thus given to the recti muscles are reflected the check ligaments, by which over-action of the muscles

is prevented; the lateral check ligaments, passing respectively from the internal rectus to the vertical crest on the lacrymal bone behind the tear sac, and from the external rectus to the malar bone are better

FIG. 3.



Tenon's capsule.

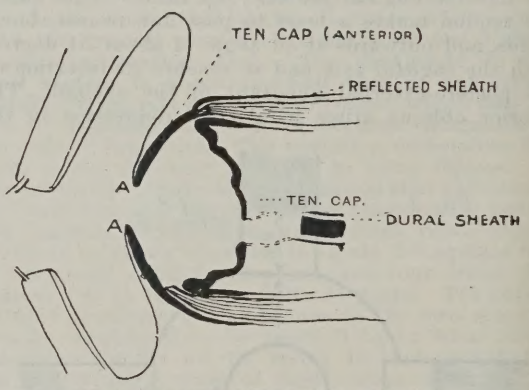
defined than those from the superior and inferior rectus which are directed forwards to the fornices of the conjunctival sac.

Bearing these facts in mind it is inconceivable that the eye can rotate as a ball within Tenon's capsule as a cup; were it to do so the whole intra-ocular circulation would be disturbed or the centripetal and centrifugal blood-vessels would be lacerated in any but the least movement, while the fibres of the optic nerve would be required to play freely up and down its dural sheath like a piston rod in its cylinder. The truth is that Tenon's fascia forms a primary bed in which the eyeball is ensconced, while globe and capsule move together upon the bed of fat, semi-fluid during life, with which the orbit is everywhere packed. The muscles of the eyeball are the only muscles of the body which enjoy the advantage of playing in an oleaginous lubricating medium; the precise results which they achieve show the orbit to be an ideal gear-box.

Nature and Production of Ocular Movements.

But not even on the cup of semi-fluid fat does the eye, ensheathed by Tenon's capsule, in the true sense of the word, rotate. In the first place, the eye is by no means a perfect sphere, and even if it be so regarded the point about which it moves is not its centre. Donders found this fixed point about which the eyeball moves to be 14·52 mm. behind the central point of the cornea in myopic eyes and 13·22 mm. in hypermetropic eyes. We may the better apprehend its situation if we locate it at 14 mm. as a rough mean for the emmetropic eye, remembering that the antero-posterior axis of such an eye measures 24 mm. All movement about this metacentral point should accordingly be regarded as an oscillation of the eye, not as a rotation. Unfortunately, the term rotation has become well entrenched. The terms rotation in or out, and up or down add to our confusion, and unnecessarily seeing that such terms as adduction, abduction, elevation and depression thought of in reference to the anterior pole of the eye are available, and ambiguous to no one. The use of these terms will leave the word rotation for a movement of the eye which never takes place in health when all the extra-ocular muscles are working normally. This potential rotation is a wheel-like movement on the antero-posterior axis; if it occurred and we imagine the eyeball as free to roll on the floor of the orbit and barrel-like in shape the term "rotation in" can be employed to describe the wheel-like movement which would cause the eye to travel towards the mid-line of the face, and the term "rotation out" for the wheel-like roll in the opposite direction; the terms "in-torsion" and "ex-torsion" have been used as alternatives, but suggest to my mind the idea of a corkscrew-like or spiral twist contorting the eyeball. Of the six extra-ocular muscles, when the eyes are in the primary position, which is the basal position from which to contemplate ocular movements, the lateral recti alone are in alignment with the movement which their contraction imparts to the eyeballs; the internal rectus is a pure adductor, the external rectus a pure abductor. The tendon of the superior oblique descends from the orbital roof, passes backwards and outwards over the top of the eye on the mesial side of the centre of movement to reach its scleral insertion near the posterior pole; its action is that of a depressor, an abductor, and an internal rotator; the inferior oblique, parallel in its course to the tendon of the superior oblique, but ascending from the floor of the orbit after having passed beneath the eyeball, is an elevator, an abductor, and an external rotator. The superior and inferior recti pass

FIG. 4.



Tenon's capsule after excision of eyeball.

forwards and outwards, making an angle of about 27 degrees with the sagittal plane, while the obliques make an angle of about 51 degrees with the same plane; the angle formed by the recti is a small one, but it enables the superior rectus to act as an adductor and internal rotator, the inferior rectus as an adductor and external rotator, though the chief function of the first is that of an elevator, of the second that of a depressor.

The scheme exhibited in Fig. 5 very ingeniously displays these muscular actions; in it variations in the length of the arrows are indicative of the amount of power in any direction which each muscle can contribute to the total required. The action of each muscle is set out in the Table; reference to it indicates

Superior rectus III. N.	Internal rectus III. N.	Inferior rectus III. N.	Inferior oblique III. N.	External rectus VI. N.	Superior oblique IV. N.

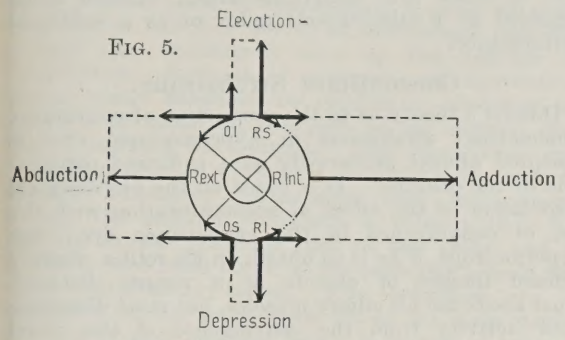
that in adduction of an eye, or in simultaneous convergence of the two eyes, as in near fixation, the

primary power is furnished by the internal rectus muscle, while precision and steadiness of movement are secured by simultaneous contraction of the superior and inferior recti, approaching their work as adductors not in the direct line of the movement to be imparted; the tendency of the one to elevate

FIG. 5.



Scheme to illustrate the action of the ocular muscles (after Marquez, from Fuchs).

the cornea will be neutralised by that of the other to depress it, while their individual capacities to produce wheel-like rotation on the antero-posterior axis will also cancel each other. It is interesting to note that each of these three muscles used in near fixation is innervated by the third cranial nerve, which supplies also the sphincter pupillæ and ciliary muscles called upon at the same time to adjust the focus of the eye for a near point. The abducting group of muscles will in convergence be acting as controls, and in turn preponderance will be given to them when required to restore the primary position of parallelism. How accurately the abducting group of one eye balances the adducting group of the other, and consequently also its own group of adductors, is demonstrated by the precision with which the two eyes can be lateralised to right or to left. Reference to Fig. 5 and to the Table again shows how the obliques supplement the pure abductor and mutually eliminate the tendency of one another to produce vertical movement or wheel-like rotation. In elevating the cornea the power is supplied by the superior rectus and the inferior oblique acting in conjunction; in depression the inferior rectus and the superior oblique form the pair of muscles to which preponderance is transmitted.

INNERVATION OF MUSCLES.

A study of the groups of nuclear nerve-cells in the fore part of the floor of the iter of Sylvius and posterior part of the floor of the third ventricle (Fig. 6) shows that the group for the superior rectus is in immediate contiguity with that for the inferior oblique, and that the group for the inferior rectus and the fourth nerve nucleus which innervates the superior oblique are in similar immediate anatomical relation to each other. In Fig. 6 it will be observed of the third nerve nucleus that only those fibres which arise from its posterior part and are destined for the supply of the inferior rectus decussate to form a bundle of the oculomotor nerve of the opposite side; this arrangement obviously harmonises with the crossing, dorsally to the iter, of the two fourth nerves, which supply the superior obliques. The posterior longitudinal bundle passes ventrally to the successive nuclei and links them together, while fibres which cross the median raphe from each sixth nerve nucleus to the opposite third nerve nucleus are, no doubt, an essential part of the mechanism for conjugate lateral movements. Once again referring to Fig. 5 we observe how the quota of wheel-like movement and of adduction which the superior rectus would tend to produce is antagonised by the tendency of its associate in elevation, the inferior oblique, in the opposite direction, and similarly in the case of the combined depressors the inferior rectus and superior oblique. When the two elevators are in preponderance the two depressors are in action as controls, and vice versa.

HARMONY OF OCULAR MOVEMENTS.

If the advantages of binocular vision are to be available, and diplopia is to be avoided in all parts of the fixation field, the greatest precision of ocular movement is obviously essential; these advantages are preserved in the primary parallel position of the visual axes by the tone of the extraocular muscles; in all other positions by the precision and accuracy of their grouped working. Yet we constantly hear and read statements implying that adduction and convergence are effected by the internal recti, abduction by the external recti. No movement of any part of the body, I imagine, needs to be more precise than the convergence of the visual axes, such as is necessary to maintain the image of a needle eye or point on the fovea of each of our two

FIG. 6.

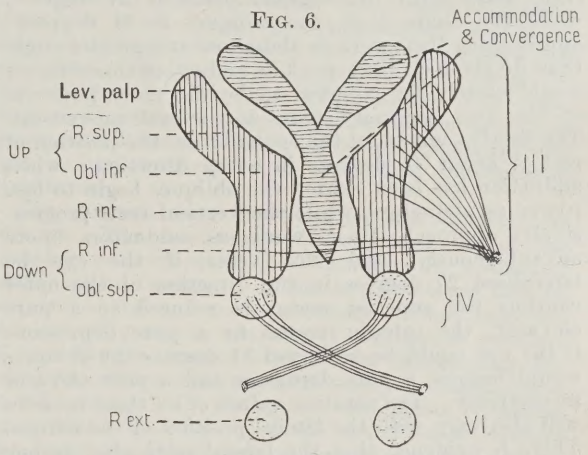


Diagram of the probable position of the nuclei of origin of the fibres to the ocular muscles in the IIIrd, IVth, and VIth nuclei (after Parsons).

eyes simultaneously. Two single strap-shaped muscles like the internal recti, operating in the direct line of the movement to be imparted to the eyeballs, could never effect this. The internal rectus, while it is the main antagonist of its fellow external rectus, is greatly its superior in power; we have already seen that it is the more bulky of the two muscles, that its fleshy belly is both the longer and the wider, and that by reason of the more anterior insertion of its tendon in relation to the centre of movement it acts at greater leverage advantage than the external rectus. If we ignore the accessory adductors and abductors we are faced with the following paradox—viz., that if for an external concomitant strabismus a surgeon tenotomises the external rectus, and on the hypothesis leaves the powerful and powerfully attached internal rectus unopposed, he can correct by his operation only about 5 degrees of the squint; on the other hand, if for the treatment of an internal concomitant strabismus he tenotomises the internal rectus and leaves the far weaker external rectus unopposed, he can correct as much as 15 degrees of squint.

The total power of abducting the eye must be equal to the total power of adducting it; the total power of elevation must be equal to the total power

of depression; potential power of wheel-like movement in (rotation in) must cancel potential power of wheel-like movement out (rotation out). The power of abduction of the external rectus supplemented by the accessory power provided by the combined action of the two obliques must be equal to the power of adduction of the internal rectus supplemented by the accessory power of the combined action of the superior and inferior recti. The external rectus being a weaker muscle than the internal rectus, the obliques contribute more to abduction than the vertical recti to adduction, and the necessary balance is achieved. Were it not so life would be intolerable from confusion of vision and the discomforts which ocular strain would induce. We now see that when the external rectus is tenotomised the adducting group is still considerably opposed by the accessory abductors; when the internal rectus is tenotomised the abducting group is opposed only by the accessory adductors, a much weaker pair of muscles for adduction than the oblique pair for abduction. Our operative experience therefore agrees with what we would expect. The angles in Fig. 7 themselves suggest this inferiority of the supplementary adductors to the supplementary abductors; the angle α which the vertical recti make with the sagittal plane is 27 degrees, while the angle β of the obliques is 51 degrees; approaching their work as abductors at a greater angle than do the recti their work as adductors the obliques would clearly be expected to be the more powerful of the two accessory pairs for lateral movement. The total excursion of the eyeball from the position of rest is about 45 degrees in every direction; when adduction has been started the obliques begin to lose power as abductors, while the vertical recti progressively approach their work as adductors more advantageously, and vice versa—if the eye be lateralised 27 degrees in the direction of the outer canthus the superior rectus is reduced to a pure elevator, the inferior rectus to a pure depressor; if the eye could be adducted 51 degrees the obliques would become a pure depressor and a pure elevator respectively. The rotation values of all these muscles will also vary with the lateral position of the cornea. There is evidence that the lateral recti also, as one would expect, acquire rotation power when the eye is directed into the upper or the lower part of the fixation field; if the external rectus is paralysed the false image remains erect only as long as the eyes are kept in the horizontal plane, or the paralysed muscle is not actively called upon; a tilting of the false image occurs when the paralysed external rectus is required to assist in turning the eye either upwards and outwards, or downwards and outwards; a slight wheel-like movement of the eye has been produced by the oblique muscle concerned in these positions when the opposing wheel-like contribution of the external rectus is absent by reason of its paralysis. It would also seem that when the cornea has risen above the horizontal level as the eye is elevated the two lateral recti in combination begin to contribute to the power of elevation, and conversely, that they will become supplementary depressors when downward movement has been initiated by the inferior rectus and the superior oblique.

We are now able to realise that even in the primary position of rest there is no extra-ocular muscle which is not by its tone essential to maintain the balance of the eye with which it is immediately concerned, and the harmony of that eye with its fellow. There can, in my opinion, be no movement in any direction imparted to an eyeball in which everyone of its extra-ocular muscles is not implicated, either as an active power or as a controlling influence. Marvellous indeed must be that musculature when we reflect that two eyes have to make excursions in complete harmony to every part of the field and at constantly changing range of fixation, and still more mysterious the physiological mechanism by which this musculature is called into active operation, whether it be regarded as a subconscious reflex or as a volitional performance.

Concomitant Strabismus.

Donder's theory as to the production of convergent concomitant strabismus in hypermetropic eyes is accepted almost universally as a sufficient explanation of the disorder. It is based on the physiological association of the effort of accommodation with the act of convergence in the emmetropic eye; the hypermetrope, if he is to obtain on his retina sharply defined images of objects at a remote distance, must needs use his ciliary muscles, but must dissociate their activity from the convergence of the visual axes with which the act of accommodation would, under normal conditions of focus, be inevitably associated; failure to accomplish this dissociation must result in convergent strabismus, one eye becoming the eye fixing the object under contemplation, the other converging at the appropriate angle and its vision being suppressed in order to avoid diplopia. That eye will unconsciously be selected as the converging one which for any reason is the less effective of the two for vision; this it may be through its being the subject of a more gross or more complicated error of focus than its fellow, or by some defect of transparency in its media or deficiency or disorder in its percipient elements.

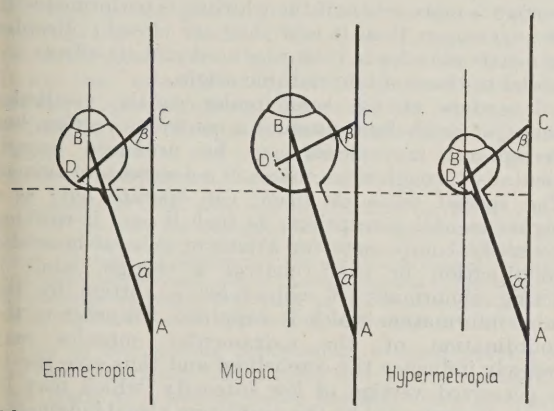
The conception of a higher fusion centre in the brain may be a convenient assumption for the purpose of discussing unsolved problems, but in my judgment can be no more than this. Among all the injuries and diseases of the brain on record, I am unaware of any case in which a patient as the result of a local cerebral lesion has lost the power of stereoscopic vision without other disturbance of visual function; a series of such cases would be necessary to demonstrate the presence and situation of the "fusion centre" if it exists anywhere but in the brains of those who postulate it.

Donder's theory, however, does not go entirely unchallenged, and does not fully satisfy in all respects every case of convergent concomitant strabismus, while its insufficiency as an interpretation of divergent concomitant strabismus in myopes is still more conspicuous. It is stated that if we regard divergence as negative convergence, the association of divergent strabismus with myopia is explicable on Donder's theory, but this statement has, I feel sure, never carried full conviction to the mind of anyone who has seriously considered it.

While the absence of the necessity for full or any accommodative effort on the part of the myope to enable him to define an object at short range may deprive him of an incentive to the associated action of convergence, it seems to me to afford no explanation of the visual axes taking up a primary position of divergence instead of parallelism in the myope; in viewing, or attempting to view, a distant object neither the emmetrope nor the myope is making any effort with his ciliary muscles. It would seem unlikely, a priori, that the convergence muscles in myopic eyes weaken from disuse, seeing that the myope usually indulges excessively in work at short ranges, for which he considers his eyes particularly efficient, while occupations which require a full range of

distant vision necessarily interest him but little. It is suggested that in the higher degrees of myopia the cumbrous elongated eyeballs are accommodated more conveniently in the orbits, if each swings outwards to take up alignment with its orbital axis. This I think is approaching a point of some importance, but it is not to be understood that the myopic eyes volitionally take up this position of convenience; there is, I maintain, an anatomical reason quite adequate to explain a tendency to outward deviation on the part of the myopic eye. Fig. 7 supplies the solution. The emmetropic eye becomes myopic by stretching, but it is in the antero-posterior diameter particularly that enlargement occurs; the addition to length is made mainly by yielding in the posterior half of the globe and a tendency to a local bulge at the posterior pole is the chief contributory factor. The deformed eye is supported on the retro-ocular fat at the same depth in the orbit as it occupied before it started to become

FIG. 7.



Scheme to show variations in angles of approach of the extra-ocular muscles, determined by differences of refraction.

myopic; accordingly the myopic eye is prominent, and in high degrees of myopia so much so that it may suggest a proptosis. The result of the altered conditions will be that the angle BAC (Fig. 7) is diminished, while the angle ACD is increased; in consequence the power of the superior and inferior recti to act in combination as accessory adductors is diminished, while that of the two obliques to act as accessory abductors is increased—the balance of power between the adducting and the abducting groups of muscles is therefore disturbed in favour of the abductors, and once an outward swing of the visual axis has been initiated the power of the accessory abductors increases while that of the accessory adductors decreases with every degree of outward deviation which is achieved, so that as soon as a preponderance of the abducting group has been established it tends automatically to increase. Even the proptosed emmetropic eyes of a patient suffering from exophthalmic goitre are frequently found to be incapable of maintaining efficient convergence; it seems to me probable that the explanation of this symptom of Graves's disease is to be found in the anatomical derangement of power, which the proptosis has produced between the adducting and abducting groups of extra-ocular muscles.

That in the myopic eye the superior oblique does approach its work more transversely and therefore at greater advantage to act as an abductor is strongly supported by the well-known observations of Fuchs on the insertions of the external muscles of the eye. Fuchs found that in the myopic eye the tendinous insertion line of the superior oblique is directed more antero-posteriorly than in the emmetropic or the hypermetropic eye, and that in the myopic eye its posterior limit does not cross the mid-sagittal plane of the eyeball, so that the whole of the line of insertion is confined to the postero-external quandrant of the globe.

It appears, therefore, that in the myope, in whom the balance of power is anatomically disturbed in favour of the abductors, parallelism of the two eyes as the primary position of rest can be obtained and maintained only if active nerve impulses inciting to contraction are constantly imparted to the adducting group; the incentive to these unwonted impulses will never be strong seeing that the call for them is non-physiological; the images of distant objects obtained by uncorrected myopic eyes are indistinct and easy to be ignored, so that avoidance of conscious diplopia is easy, while if one eye from any cause fails to contribute a practical share to binocular vision the position of greatest comfort will be assumed—i.e., a divergent strabismus will become established. In the flattened hypermetropic eye, where Donder's theory is more satisfying, consideration of Fig. 7 suggests that the changes in the muscular angles will be exactly the reverse of those which occur in the myopic eye—in the hypermetropic eye the balance of power is upset in favour of the adducting group, and I see no reason for entirely ignoring this fact in the consideration of convergent concomitant strabismus.

The position may be summed up concisely as follows. The simultaneous harmonised use of the focusing muscles with the adductors is a natural physiological function. If the hypermetrope fails to acquire the habit of accommodating without innervating his adductors a convergent strabismus results; if the myope cannot succeed in innervating his adductors without the stimulus which accommodation would supply a divergent strabismus results; anatomical disturbance of the extra-ocular muscles is a factor in each variety of concomitant strabismus, and especially conspicuous and primary in the case of the myope. Our operative treatment of concomitant strabismus is logical only if we concede that anatomical derangement is one of the chief elements in its production.

Ocular Contributions to Equilibrium.

Visual judgments and information derived from impulses generated in the extra-ocular muscles are elements which contribute to our sense of equilibrium. A picture of everything in the field of vision is formed on each retina simultaneously, and the image of each object in the field is projected outwards along the secondary axis passing through the nodal point of the eye to its correct position in space. Our visual appreciation of their relation to one another of the objects in space by which we are surrounded is known as objective orientation. In men and primates which enjoy the advantages of stereoscopic binocular vision, accuracy of alignment of the two eyes dependent on their perfect muscle balance is essential, or the information derived from one eye will contradict, not supplement, that derived from the other; in consequence the diplopia and false judgments will be so disturbing that the patient will prefer to close one eye and depend upon such restricted information as he can obtain by monocular vision. Objective orientation, then, is a purely visual function operative only when retinal stimuli influence consciousness as highly organised visual perceptions; as far therefore as

it is contributory to our sense of position and equilibrium it differs from articular and muscular sense, and from the guidance which we derive from the semicircular canals; these stimuli acting subconsciously are not under volitional control, and except during natural or artificial sleep are at all times operative. Assuming that we have a correct sense of body balance, and of the position of the head, it is however also necessary that our external eye muscles shall be accurately coördinated if by the sense of sight we are to estimate our personal relationship to objects in the world around us. By the muscular sense of our extra-ocular muscles we learn, subconsciously, the position of our eyes in our heads, and their alignment in regard to external objects; this is what is meant by the term subjective orientation, disorder of which function results in false judgment of our own position and a sense of want of balance or giddiness which is not experienced as the result of the conscious processes which constitute false objective orientation, or as it is sometimes called false projection. If the balance of our eye muscles is disarranged we must inevitably draw erroneous inferences, because, unknown to us, the premisses are false, while if definite ophthalmoplegia externa be present diplopia from false projection will complete our confusion.

The relation between the values of objective and subjective orientation is interesting. Occasionally a patient is met with who having developed paralysis of a muscle—e.g., the external rectus in his better seeing eye—still prefers to employ this eye and avoids diplopia by covering the non-paralysed eye of less visual acuity. If this has been his habit for any length of time testing will reveal that the patient is the subject of confused judgments when made to use the non-paralysed eye alone, and he walks unsteadily if he attempts to guide himself with this eye. Presumably he has established a new sense of values for the musculature in the interest of his paralysed eye. The existence of such cases suggests that the eye plays only a subsidiary part in the maintenance of equilibrium; a patient who has totally lost one eye experiences no sense of vertigo, and it appears to be not difficult to learn to use one eye for guiding our movements, even when its musculature is in a state of disorder. Nevertheless objective and more conspicuously subjective orientation do play a part in the maintenance of balance. Romberg's test is applied to tabetics with their eyes closed; if allowed to have his eyes in use a tabetic is able by visual judgments to nullify his tendency to sway when standing on a small base; on the other hand, any vertigo of purely ocular origin is relieved by closing the eyes. Labyrinthine nystagmus or the clonic spasm of compositor's nystagmus cause stationary objects to appear to be in oscillation. Labyrinthine nystagmus results from disordered influences generated in the semicircular canals; transmitted by the vestibular nerve these stimuli reach a group of neurons laterally placed in the upper part of the floor of the fourth ventricle, known as Deiter's nucleus, whence they are reflected along the nerves to the extra-ocular muscles. The cells of Deiter's nucleus are connected through the spinal cord and peripheral nerves with the skeletal muscles and receiving from them proprioceptive impulses dependent on their tone and muscular sense relay them to the cerebellum for the promotion of body balance. The nucleus is also put into communication by the posterior longitudinal bundle with the nuclei of origin of the third, fourth, and sixth nerves, particularly with those of the opposite side, though also with those of its own side. It is therefore reasonable to suppose that the extra-ocular muscles like other skeletal muscles contribute their quota of stimulus to the cerebellar centres via Deiter's nucleus, and that in a state of disorder they may help in this way to provoke a sense of vertigo; such an explanation might apply to the giddiness of insular sclerosis when nystagmus or diplopia are present. It has recently been suggested that the proprioceptive impulses generated in the extra-ocular muscles are transmitted through the third nerve, then by the communications which this nerve makes in the outer wall of the cavernous sinus to the fifth nerve, and thus to the nuclear cells of the brain stem. Clinical evidence, however, seems to support the view that the route is direct throughout by the third nerve. Where the Gasserian ganglion has been destroyed by disease, surgically excised, or its large sensory root cut behind the petrous bone, the patient, as far as I am aware, experiences no sense of want of balance or disturbance of his visual judgments. The schoolboy trick of bending the head on top of a cricket stump and whirling round it several times produces a sense of intense giddiness—this, of course, is mainly due to the semicircular canals, but the vertigo is more severe if the whirling is performed with the eyes open than it is if they are closed; disorder of ocular muscles is then produced and its effects are added to those of labyrinthine origin.

Disorders of the semicircular canals, vestibular nerve, or cerebellum produce a conscious vertigo, but vertiginous movements can be produced experimentally through these routes in a decerebrate animal. The special sense of vision can operate only as a higher mental perception; as such it can, if working normally, compensate for a lack of general muscular coördination or even control a vertigo, while if acting abnormally it aggravates a vertigo by the false information which it supplies. Disorder in the coördination of the extra-ocular muscles may reflexly influence the cerebellum and thus give rise to a perceived vertigo of low intensity, which may be further aggravated by the conflicting visual judgments. Accurate visual judgments may serve to arbitrate when the stimuli from other sources necessary to equilibrium are inharmonious, and may thereby suppress any sense of vertigo; apart from disorder of the ocular muscles the sense of sight will not itself produce any appreciation of true giddiness. Neither the sense of sight nor information from the ocular muscles is essential for the maintenance of equilibrium. Abnormal visual impulses generated in a disordered retina will produce no sense of vertigo if they are normally transmitted to and projected on the sensorium, though they may disturb visual impressions owing to metamorphopsia.

Visual Judgments in Sport.

A very simple form of visual judgment is called for in rifle shooting at the butts. The range being known the sights of the weapon are adjusted for the required distance. Ignoring the question of making any allowance for deflection of the bullet by air currents the marksman, rapidly adjusting his accommodation has now but to ascertain with one eye (the right if he shoots from his right shoulder) that the bull, the foresight, and backsight are in one straight line, and if he accomplishes this and is sufficiently expert to maintain an accurate weapon in this position while he pulls his trigger a bull's-eye must result. By reason of his capacity rapidly to exercise a large amplitude of accommodation the younger man has an advantage over the older, but a very emmetropic eye is hardly an essential.

In the very early days of flying a patient came to me who was building his own aeroplane; if it turned out

success it was his intention to fly it at the second meeting ever held in Great Britain. He was the subject of 6·0 D. of astigmatism and had never worn any correcting lenses. He told me he was absolutely accurate in detecting any departure from truth when he looked along the edge of a spar in course of preparation in his workshop. His joiner invariably confirmed his observation when he applied a straight edge at the point he indicated. No doubt his capacity in this matter was exceptional, as such an edge when focused by his astigmatic eye would be to him a particularly hard line in contrast with the very blurred definition of everything at right angles to it. I prescribed correcting cylinder lenses for the astigmatism, but advised my patient on no account to fly in them; the definition he would have obtained would, I felt sure, so disturb his accustomed judgments of distance that he would have made a false landing probably with disastrous results. This was his second plane. His first, at the urgent request of his relations, he had tried on his chauffeur, warning him only to taxi along the ground, and at once to shut off the engine if he did feel her lift off the ground, a thing at that early date practically unknown at the first attempt. So successful had he been, however, that the machine rose 40 feet into the air after a very short run, whereupon his chauffeur shut off the engine and smashed up the plane at a cost of some material injuries to himself and £2000 to his employer.

By the present date it has been recognised that perfection in the balance of the extra-ocular muscles is desirable in air pilots, and careful tests to exclude heterophoria are made of the eyes of candidates for the Air Force before they are accepted for training. It has been established by statistics that pilots who are the subject of heterophoria make bad landings, due to their imperfect capacity to estimate their height by vision. Practice and experience may, however, do much to compensate for visual deficiency.

A patient of mine who was an officer in the Royal Naval Air Service lost the central vision and upper part of the field of vision of his right eye by reason of a retinal detachment; though his position in the service no longer required him to do so, he continued to indulge himself in the pleasure of piloting machines, and had no particular difficulty in making good descents whether on to land or to water.

One of the leading professional billiard players of the last generation had a right eye which was highly amblyopic as it had squinted inwards when he was a boy; its central vision was less than 6/60; his left eye had full vision and he demonstrated to me his attitude when playing his shots at billiards. Being a right-handed player he took up such a position as enabled him to look along the line of his shot with his left eye—to do this he kept his eyes fully lateralised to the left. By much practice and making full use of the advantages of simultaneous contrast of light and shade he must have judged distances with an accuracy quite exceptional for one to whom stereoscopic vision was denied. A billiard player, fully equipped with vision, makes his bridge and adjusts his cue on it, for the shot he has selected, with the help of sight, but at the moment of delivering his stroke his eyes are fixed on that portion of the object ball with which he intends the cue ball to make contact; by long practice he has acquired the capacity by tactile sense and muscular sense alone to operate his cue, once he has it in position, with the required accuracy.

I believe the process to be similar in game shooting with a shot gun. In shooting at driven game or rabbits the experienced shot estimates binocularly the position and range of the object, and has little or no time to align his gun by the help of vision, using his sight eye if it is from his right shoulder that he shoots. I learn from treatises on shooting that the expert shoots with both his eyes open; that he does not know how he aims; that he should not dwell on his game or follow it with his barrel but learn to drop it as soon as his gun comes to his shoulder; moreover, seeing that to kill properly he has to shoot ahead of his bird he has no actual object on which to align his weapon by sight even if he wished to do so. The truth is that the sportsman judges by vision the position at which he anticipates his charge of shot will intercept the head of his bird, and by practice becomes expert in pointing his gun to that position, guiding himself by the articular and muscular sense of his arms. He really does not sight his gun at all. The American is an expert at snap shooting with a revolver. I am informed that it is his habit to point at his mark with the first finger of the hand in which he holds his weapon extended parallel with the line of his barrel and to pull the trigger with his second finger. He no doubt keeps his eyes fixed on the target, not uncommonly his armed antagonist, and supplements usefully such rapid visual judgments as he makes by the joint and muscular sense of his upper limb and its index-finger. The idea of the master eye is, I believe, a fallacy but one found very useful by the gunsmith. A man who has been shooting badly is asked by his gunmaker to point a gun at a certain mark some yards away; when he has done this the tradesman, looking along the barrel, finds that it is directed, say, to the left of the mark, and informs him that his left is his master eye; the gun is, of course, actually being pointed too much in the line of vision of the right eye and too little in that of the left; a cast-off gun is recommended, made and sold, and with it its owner makes better shooting. He is, of course, sighting the new gun no more and no less than he was the old one, but bringing it to his shoulder, guided by proprioceptive impulses, exactly as he did the former weapon the "cast-off" results in his charge of shot being thrown more to the right and better results are obtained. If he did as a matter of fact sight his new gun he would be looking along a barrel straight from breech to muzzle, and as far as vision is concerned the fact that the barrel was set at an angle to the stock could make no difference at all. What had gone wrong with the man was that he had gradually and imperceptibly to himself lost accuracy in coördinating his upper limb movements when bringing his gun to his shoulder, so that he was not, subconsciously, pointing it to the position upon which both his eyes were fixed, and to which he believed himself to be directing it. Master eyes are not invoked to explain bad billiards, and except in Gilbertian opera a cast-off cue is not suggested as an advantage to anyone playing the game and then only if it be in the hands of his opponent.

To be reduced to one eye is, however, a great disadvantage in judging the position and distance of an object, and in this respect is an impediment to good shooting. A patient from whom I had excised one eye told me that on one occasion when a gnat buzzed a yard or so beyond the end of the muzzle of his gun he only just refrained from firing: the insect subtended an angle similar to that of a bird at a range of perhaps 30 yards and he had thought it to be a partridge. In 1923 I extracted a secondary cyclitic cataract from the left eye of a man, 42 years of age; his right eye was a soft shrunken eye which had been useless all his life, deviated outwards, and for vision had barely perception of light. The eye upon which I operated did very well, and was corrected for distance by +13·5 D. spherical, with which it saw 6/5 well, and even some letters of 6/4. I saw this man two and a half years later and was surprised when he told me that he had been successfully shooting both pheasants and rabbits. He had, of course, never enjoyed the advanatge of binocular visual judgments, but his capacity with an aphakic left eye, statically corrected with a strong convex lens, leads one to think that for the pointing of a shot-gun trained tactile and muscular sense are the chief requirements, while sight

is used to judge the range and position of the mark upon which the vision is kept fixed. Certain occupations and sports involve the use not only of the muscles of the arms but also of all the big muscles of the trunk and lower limbs. In many of these instances accuracy of impact between the implement employed and the object to be struck has to be secured as the primary necessity. For such vigorous and difficult work the sense of vision is all important; no amount of muscular and tactile sense alone could be trained adequately to secure the precision demanded. When a navvy is using a sledge hammer on a steel wedge to break up a road foundation, having measured his distance he never takes his eyes off the top of the wedge as he swings his hammer and he never misses his mark. The sense of sight is essential in hitting a golf ball; all the big muscles of the body are called into play in the swing and the eye must never be taken off the ball, preferably the back of the ball; only if guided by vision can accuracy of impact between the face of the club and the ball be secured in so violent a movement. Similar visual guidance is essential for successful goal kicking at Rugby football. In cricket and lawn tennis, though the implements are bigger than in golf, the ball should be received on the middle of the bat or racket, while there is the additional difficulty that the ball is in rapid movement; in each of these games the ball, approaching the player at considerable velocity and liable to spin or swerve in its progress, has to be watched by the player's eyes on to his bat or racket from the moment it is delivered by his opponent, or his reply will be futile. The player does well to restrain the vigour of his muscular efforts at the outset; this is the process known as "getting his eye in," but its essence consists in establishing subconscious concord between his muscular efforts and his visual judgments. Sir James Barrie once narrated that he had twice played cricket and told us "that on the first occasion he made one run, but on the second he was less successful." Sir John Bland-Sutton, in his last book not only confesses his incapacity as a batsman, but being a scientific man is able to give the correct explanation of his failure; he states "that he could not avoid shutting his eyes when trying to hit a moving ball." It is noteworthy that in his early days Sir John had worked with George Critchett, and, fascinated with his manual dexterity, had so seriously contemplated becoming an ophthalmic surgeon that with Fuchs he studied for a year in Arlt's clinic in Vienna. Ophthalmology was a great loser, but this college gained much when he decided to devote his life to pathology and the science and art of general surgery.

It will be observed that I have not been discussing *how* the eye operates in guiding muscular efforts. To do this would involve not only physiological considerations, but also others which are psychological and metaphysical, seeing that concepts of time and space are involved. We should be launching on a large uncharted sea if I endeavoured to extend my observations in any of these directions.

Importance of Sight.

If anyone should accuse me of having dealt with a subject not immediately bearing on surgery, I would point out that vision and the function of the eyes is the paramount sense by which all science has been evolved. Prof. Abel Rey, of the Sorbonne, in a book published this year in Paris in the "Evolution of Humanity" series gives a comprehensive study of oriental science before the Hellenic period. After reviewing all that was known of mathematics, astronomy, and medicine by Chaldeans, Assyrians, Chinese, Indians, and Egyptians, he sums up his conclusions. According to Prof. Rey it is owing to the development of the sense of sight that man has attained to his supremacy in the animal world. The senses of smell, of hearing, of touch could never have sufficed or been elaborated to enable man to form any ideas of notation, of mensuration, mathematics, or any branch of science as we know it to-day; in many of the lower animals one or more of these other special senses is far more acute than in the human subject. The development of the neopallium is the great characteristic of the brain of man; to it have been transferred and in it have been elaborated functions hitherto performed at a much more lowly level in mid-brain nuclei; the large areas of cerebral cortex devoted to vision, visual memory, and ocular movements are anatomical confirmation of Prof. Rey's philosophical deductions. Vision, he says, is the scientific sense par excellence; human experience is in great part visual; would it be an exaggeration, he asks, to say that experience which is, or tends to be, scientific is entirely visual? No apology therefore need, I trust, be offered by anyone who is inclined to meditate on the function of the eyes.

THE MEDICAL TREATMENT OF ANTHRAX.

By C. G. Brentnall, *M.C.*, M.B. Manch.,
hon. physician to warrington infirmary.

The report of the Chief Inspector of Factories for 1929 shows that excision of a "malignant pustule" is still practised in this country. A comparison between this method and the purely medical treatment of cutaneous anthrax may therefore be serviceable. The cases here reviewed have all occurred in the same district and are, as nearly as may be, similar in occupation, site, and severity of infection.

Before proceeding to discuss these cases in detail, it may be of interest to give a short historical account of the methods of medical treatment which are now employed.

Serotherapy.—The use of large doses of anti-anthrax serum was first practised by Bandi, who published the results in two cases. One of these patients had become comatose after surgical treatment. An intravenous dose of 150 c.cm. of serum, followed later in the day by a further 50 c.cm. by the same route, was so successful that, after a further 40 c.cm. on the following day, the patient recovered. However, serum in large doses intravenously does not seem to have been employed again until Eichhorn, in 1919, recommended it in doses of 200 to 300 c.cm. every three to six hours in cases of anthrax septicæmia. From 1920 onwards Regan, Santee, Symmers, and others took the view that every case should be suspected as septicæmia from the outset and 200 c.cm. of serum became with them a usual preliminary dose, combined with local injections of 10 c.cm. of serum every four hours, applied just outside the blanched zone of the lesion.

In this country Eurich and Hodgson have used doses of 80 c.cm. and upwards, and the latter now advises a dose of 150 to 300 c.cm. as a preliminary repeated as may be necessary until the temperature falls to normal. Symmers has used a total of 1100 c.cm. in one case, and Hodgson has found it necessary to exceed this dosage. Eurich, on the other hand, has

never needed to use more than 300 c.cm. in any case occurring in the wool industry.

Chemotherapy.—Ehrlich suggested that salvarsan might be usefully employed in these cases, and Eurich and Becker adopted this suggestion with good results, either with or without serum as additional treatment. Eurich and Pijper have also used neo-salvarsan with success, and both advocate full doses (0·6 to 0·9 g.). In one case Pijper gave 0·9 g. daily for three successive days and a fourth dose after a week's interval, making a total of 3·6 g., equivalent to about 10 gr. of white arsenic. The patient was cured. Smaller doses have, in my very limited experience, been useless by themselves, though as an adjunct they appear to have some value, in single or double doses.

Local treatment by injection of 10 c.cm. of serum every four hours around the "pustule" is practised with excellent results by Regan, Santee, and Symmers, and the latter advocates the use of no other local treatment, believing that a sterile dressing is all that is necessary. Most writers, however, advise an antiseptic dressing. Eurich lays great stress on the importance of immobilisation, which is also used as a part of Pijper's routine.

Medical versus Surgical Treatment.

At the commencement of 1929 surgical measures at the Warrington Infirmary were abandoned; even the use of local antiseptic dressings was discontinued. This course was followed in the hope that general treatment could be stopped when bacilli were no longer found in the original lesion. It was supposed that if bacilli disappeared from the "pustule" then, even if the temperature was still raised, the further use of expensive doses of serum would be unnecessary and could be discontinued. The same applied to the use of organic arsenic and its attendant danger.

The results are of interest and are set out later. A short comparison of surgical and medical treatment is given in Tables I. and II. By courtesy of my surgical colleagues I am enabled to publish the results of surgical treatment (combined with serum) in 1927 and 1928 (Table I.). Table II. shows the results of medical treatment from the end of 1928 to the time of writing.

TABLE I.

Cases Treated Surgically, 1927–28.

Case.	Sex and age.	Site of lesion.	Days in hosp.	Result.
1	M. 31	Back of neck.	16	Cured.
2	M. 66	Right cheek.	32	,,
3	M. 47	Right arm.	45	,,
4	M. 25	Right arm.	23	,,
5	M. 36	Left eyelid.	62	,,
6	M. 36	Left neck.	40	,,
7	M. 56	Left neck.	4	Died.
8	M. 27	Left neck.	24	Cured.
9	F. 37	?	4	Died.†
10	M. 43	Right arm.	21	Cured.
11	M. 54	Right neck.	5	Died.†

† Died in coma.
Average time in hospital of cured cases: 32·8 days.

TABLE II.

Cases Treated Medically, 1929–30.

Sex and age.	Site of lesion.	Days in hosp.	Result.
M. 35	Left eyelid.	13	Cured.
M. 26	Left neck.	10	,,
M. 52	Left cheek.	7	,,
M. 61	Left neck.	8	,,*
M. 21	Back of neck.	8	,,
M. 41	Right eyelid.	4	Died.†
F. 36	Right cheek.	3	,,†
M. 22	Left jaw.	9	Cured.
M. 16	Left cheek.	5	,,
M. 33	Right forearm.	12	,,
M. 56	Right chin.	8	,,

* Died six weeks later of exfoliative dermatitis.
Average time in hospital of cured cases: 9 days.

Fifteen of the twenty-two cases occurred in the season December to May inclusive. The Chief Inspector of Factories was communicated with on this point, and by his courtesy I am permitted to publish the following extract from his reply: "Curiously enough, I have been looking into the matter myself, and in the five years 1925 to 1929, from December to May, the cases amongst tanners were 45 out of a total of 69. Similarly, in those cases occurring in docks, from November to April, 21 out of 27 occurred during that period." The same tendency to a seasonal increase of anthrax is revealed less conclusively in figures supplied by the courtesy of the manager of the United Tanners' Federation. In the past ten years 51 cases of anthrax have been reported to the Federation, and 34 of these occurred between December and May. These figures include some of the cases already mentioned above, while others have not come under the survey of this organisation. Further investigation as to a seasonal incidence in this country, and its cause, should prove interesting.

A more detailed account of the 11 medically treated cases is given below.

Case Reports.

All cases showed anthrax bacilli in smear and culture during the course of treatment. All serum was given intravenously except where (M) denotes intramuscular dosage or (T) intrathecal.

CASE 1.—Two days' infection. No initial lesion. Malignant anthrax œdema. Surgically inoperable and regarded as hopeless. Both sides of face and right side of neck swollen. From right eyebrow to right malar bone swelling was hard and purple. Treatment: first day, 60 c.cm. serum (M); second day, 80 c.cm. serum (M), 150 c.cm. serum, and 0·6 g. stabilarsan; third day, 160 c.cm. serum and 0·6 g. stabilarsan; fourth day, 80 c.cm. serum and 0·45 g. stabilarsan; fifth day, 80 c.cm. serum.

CASE 2.—Five days' infection. Well-marked eschar. Resistance apparently good. Treatment: first day 50 c.cm. serum and 0·6 g. stabilarsan. Second and fourth days 0·6 g. stabilarsan.

CASE 3.—Two days' infection. Well-marked signs. On fifth day, no œdema and no enlarged lymph glands; eschar had enlarged and fresh vesicles had appeared in areola. Treatment: Daily injection of 0·6 g. stabilarsan for five successive days.

CASE 4.—Malignant anthrax œdema four and a half hours after a blow from a hide. Treated within six hours of infection. With treatment resistance apparently improved, since eschar and areola appeared on third day. Less swelling and much more vesiculation (becoming pustular) on fourth day. Further pustulation on fifth day, but swelling and induration were less. Blood in pustules also. Œdema probably obscured any enlarged lymph glands. Discharged at his own request on eighth day. One month later an urticarial œdema observed; patient readmitted after five weeks, and died five days later from exfoliative dermatitis. Chronic nephritis found at autopsy, otherwise internal organs appeared normal. Arsenic found in liver, spleen, kidneys, and skin; none in hair or nails. Treatment: first day 0·6 g. stabilarsan; second day, 0·45 g. stabilarsan; third day, 0·45 g. stabilarsan, and 200 c.cm. serum; 0·45 g. stabilarsan; fourth day, 0·3 g. stabilarsan; 100 c.cm. serum and 50 c.cm. serum (M); fifth day, 0·3 g. stabilarsan and 100 c.cm. serum; sixth day 0·3 g. stabilarsan and 100 c.cm. serum.

CASE 5.—Five days' infection. General condition bad; pulse-rate 110. Considerable swelling of neck; albuminuria present. Treatment: first day, 0·45 g. neosalvarsan and 200 c.cm. serum. Second and third days, 200 c.cm. daily.

CASE 6.—Three days' infection. Commenced clinically as a typical staphylococcal pustule. Next day, anthrax œdema. Patient apparently comfortable on third day of treatment, but pulse uncountable and leucocyte count 10,400 per c.mm. On fourth day, restlessness, acute mental anxiety, severe præcordial pain, vomiting, dyspnœa, pulseless, clammy, then death in coma. No anthrax bacilli in smear or culture from lesion on day of death. Pure colonies of staphylococci found. Treatment: first day, 100 c.cm.

serum, 100 c.cm. serum (M) and 0·45 g. neosalvarsan; 200 c.cm. serum. Second day, 200 c.cm. serum.

CASE 7.—Four days' infection. Clinically a slight furuncle. Atypical anthrax bacilli in smear. Given 40 c.cm. serum as a precaution till culture result known. On second day apparently comfortable. No bacilli in smear or culture on third day, but staphylococci in large numbers. No result from guinea-pig inoculation. Sudden coma and death.

Post-mortem examination four days later: brain congested; dura mater adherent; no hæmorrhages. Heart and liver paler than usual, otherwise normal, no hæmorrhages. Kidneys paler than normal, no clear demarcation between medulla and cortex; a few dusky spots with blurred outlines (? hæmorrhages) on cut surface. Spleen enlarged, black, very friable and soft. Anthrax bacilli found in brain and meninges, not in other organs. Treatment: first day, 40 c.cm., second day, 200 c.cm. (M); third day, 200 c.cm.

CASE 8.—Four days' infection. Retained in hospital on account of rise in temperature and slight jaundice, with slight joint pains. Treatment: first day, 200 c.cm. serum and 0·45 g. neosalvarsan; second day, 200 c.cm. serum.

CASE 9.—Three days' infection. Lymph gland became enlarged four days after admission. Treatment: first day, 200 c.cm. serum; second day, 200 c.cm. serum.

CASE 10.—Four days' infection. Bacilli 250 to a field on admission. At noon on third day two uncapsulated, small, badly staining bacilli only were found in the whole smear. Headache and nausea, with vomiting once or twice in the first three days; headache easily controlled by aspirin. Temperature rising on third and fourth days. Lumbar puncture showed blood-stained cerebro-spinal fluid. Patient collapsed after intrathecal serum. Apparently moribund. Rigid neck and Kernig's sign from the time they were first looked for (fourth day) until the ninth day. On fourth night Cheyne-Stokes respiration appeared. Swelling and headache much less on fifth day. Severe rigor after serum on fifth day. No headache, and only slight swelling and Kernig's sign on seventh day. Rise of temperature and itching of skin on ninth day. Treatment: first day, 0·45 g. neosalvarsan; second day, 0·45 g. neosalvarsan; third day, 200 c.cm. serum; fourth day, 180 c.cm. serum and 20 c.cm. serum (T); fifth day, 100 c.cm. serum and 20 c.cm. serum (T).

CASE 11.—Three days' infection. Symptoms of a "cold in the nose" after first intramuscular injection. Severe dyspnœa and cyanosis after first intravenous injection of 20 c.cm. serum. Further attacks of dyspnœa and cyanosis after all other injections when the dose exceeded 10 c.cm. of undiluted serum. Feeble heart sounds and epigastric pulsation present one month after.

Discussion.

Certain results shown in the above résumé seem to be worth attention. In all cases in the series treated medically (although the notes are incomplete on this point), anthrax bacilli had disappeared or greatly diminished in the local lesion, but there was not necessarily a corresponding fall in the temperature. In Case 3, treated by arsenic only, bacilli disappeared and the temperature fell on the same day. In Cases 8 and 9 treatment was stopped when bacilli were no longer found in the "pustule," and both cases recovered, though the temperature did not return to normal until from one to three days afterwards. Cases 6 and 7, though the lesion was apparently free from anthrax, both died, and anthrax meningitis was discovered at autopsy in one. In Case 10 the initial lesion was apparently free of anthrax on the third day, but clinical evidence of anthrax meningitis was discovered on the following day.

The bacteriology of the "pustule," then, is unreliable as a guide to the progress of the disease. In Cases 6, 7, and 10 staphylococci were found in considerable numbers in the original lesion, and this may be the solution of the problem presented by an anthrax-free skin lesion in a patient profoundly infected by the bacillus.

Frank concluded, from a study of mixed anthrax infections in guinea-pigs and mice, that staphylococci inhibit the growth of *Bacillus anthracis*. Two of these cases revealed a mixed infection in what seemed from naked-eye appearances to be a staphylococcal lesion. In general, however, the original lesion is not pustular. "Striking," says Santee, "are the absence of pus, the absence of much pain or tenderness, the non-pitting or semi-solidity of this huge œdema, and in most of these cases the absence of enlargement of the draining nodes." Eurich and Hodgson express themselves equally emphatically on the misnamed "pustule"; and such indeed is the impression retained by me. The presence of pus, however, does not contra-indicate anthrax, as appears evident from Cases 6 and 7 especially and from the case reported by Cleland.

Enlarged lymph glands may on further investigation prove to be a comparatively late manifestation of the disease. They were not found in Cases 3, 4, and 9, and my impression (from memory only) is that they were also absent in Case 1.

"The development of a localised pustule indicates a degree of resistance to the bacteria, while a widespread œdema is evidence of failure of the tissue to prevent the advance of the infection." This statement by McGlannan appears to be supported by the clinical progress of Case 4; here, four and a half hours after receiving a blow from a raw hide, a malignant anthrax erysipelas occurred and advanced in spite of arsenical treatment. As the disease checked, so did the eschar and vesiculation appear and increase, while swelling diminished, until the maximum of vesiculation was reached on the fifth day. It will be seen that this case was first treated with stabilarsan, and that serum was not used until later.

The case for chemotherapy is enthusiastically summarised by Canwright, and Pijper's excellent results lead him naturally to claim that the use of organic arsenic is safe. I cannot go so far in my advocacy. Such small evidence as appears above gives support to the views of Eurich and Pijper that dull doses are necessary. I suggest that, when anthrax infection is cured, an immediate course of treatment by sodium thiosulphate should follow; but would not the use of serum in the first instance prove to be the shorter and safer treatment after all?

A single dose of neosalvarsan may not only have a beneficial direct effect, but its indirect action may also be of value. Walker's work on rabbits, though affording no proof of this, suggests it, but suggests further that repeated doses may interfere with natural immunising processes. If an arsenical is to be used, the clinical and biochemical examination of the patient must be made with care, and the previous history will also, of course, be important. Here a difficulty arises. The patient's own inability to give correct information may at times be a serious bar to the safe use of this remedy. Moreover, the question of compensation may introduce a complication. Doubtless the patient should give a correct personal history, but doubtless also he and his relations are under a temptation not to do so. In spite of these considerations, neosalvarsan should be borne in mind as an effective remedy in such hospitals as are called upon to treat anthrax without having a supply of anti-anthrax serum at their immediate disposal. Time is an all-important factor, and 12 or 24 hours saved in commencing treatment may make all the difference to the result.

ANTHRAX MENINGITIS.

Meningitis is usually regarded as a rare complication of cutaneous anthrax. Kauffman makes no reference to it, and Zingher in a single paragraph dismisses it as resembling ordinary meningitis when

it occurs. It will be noticed that of the 22 cases reviewed above four died in coma. Two of these were examined post mortem. One (Case 7, Table II.) was proved to have anthrax meningitis. The other (Table I., Case 11) not only contained anthrax bacilli in meninges, brain, heart, and liver, but also showed hæmorrhage into both parietal lobes and the cerebellum. Eurich has not infrequently found extravasations of blood between the brain and spinal cord and into the lateral ventricles. In Santee's cases "several autopsy reports showed in addition to the septicæmia . . . a pial œdema or congestion with the formation of small hæmorrhagic foci." Ellis reports a case of apparent recovery from anthrax in which headache was followed by death within six hours. Cerebral hæmorrhage and meningitis were found. Kraus and Spikes and Cleland found meningitis or congestion of the brain in both their cases. During life, however, meningitis does not appear to be a conspicuous part of the picture; in the four cases referred to above it was neither suspected nor examined for until coma was evident. In the one case of meningitis that recovered the bedside appearance did not suggest meningitis, although rigidity of the neck and Kernig's sign were revealed by examination after the cerebro-spinal fluid had shown evidence of meningitis. As regards the central nervous system, these cases have not therefore conformed to Zingher's description but rather to that by Symmers, who is alluding to septicæmia: "While the anthrax pustule itself offers a forbidding aspect, the appearance of the patient, on the contrary, is apt to give one the impression of extraordinary tranquillity."

In animals the onset of death may be masked almost to the very end. One wonders if the painlessness of the disease which is so evident in the local lesion may not have its counterpart in an analgesic condition of the central nervous system when the disease is general. It might be well to look for nervous symptoms in all cases, and not to spare the use of lumbar puncture for both diagnosis and treatment. It is possible that by such means the heavy dosage that is occasionally necessary might be much diminished.

Conclusions.

A comparison of the combined surgical and serum treatment of cutaneous anthrax, and of medical treatment alone, shows that recovery is quicker by the latter method. This comparison is made from cases which all occurred in the same district, under much the same conditions of infection as regards site and severity.

Amongst tanners, cutaneous anthrax tends to occur more frequently in winter and spring (and mainly amongst those employed on "dry" hides).

Organic arsenic, if used, should be given in large doses. Smaller doses do not appear to have sufficient therapeutic effect to justify their use, and their cumulative effect is probably as dangerous as that of one or two large doses.

Staphylococci appear to assist in inhibiting the growth in cutaneous lesions. The presence of pus is not necessarily a contra-indication of the existence of anthrax in a lesion.

Anthrax meningitis is apparently insidious in onset, and may be more common than is usually suspected.

I am indebted to Dr. H. A. Mitchell for the bacteriological reports cited in these cases, and to Dr. Robert Coope for his criticism and encouragement in the preparation of this paper.

URINARY CREATININE AS A TEST OF RENAL EFFICIENCY.

By A. Muir Crawford, M.D., F.R.F.P.S. Glasg.,
PHYSICIAN, ROYAL INFIRMARY, GLASGOW.

It is now generally recognised that the retention of creatinine in the blood is a constant accompaniment of advanced cases of nephritis and also that the degree of retention may be taken as an index of the degree of renal damage or impairment of kidney function. The normal amount of creatinine in the blood varies from 1 to 2 mg. per cent., and Myers and Killian [1] have shown that an increase of blood creatinine above 5 mg. per cent. points to a serious impairment of the excreting power of the kidneys and indicates a grave prognosis. In such cases death almost invariably follows in a short time. These observers conclude that in cases of advanced nephritis the blood creatinine furnishes a more reliable prognosis than any other test, and that in cases showing a considerable retention of urea, without retention of creatinine, ultimate improvement may take place. Patch and Rabinowitch [2] also, in a large series of observations, found that, in spite of high blood-urea values, symptoms of uræmia were usually absent when the creatinine values were normal or nearly normal.

Our knowledge of the physiology of creatinine is neither extensive nor accurate, but certain important facts are generally accepted. 1. It is probably a waste product and, on a meat-free diet, it is derived entirely from endogenous metabolism. 2. Its formation and excretion are normally very constant. 3. The daily output in man varies from 0·8 to 2 g. and the amount for a given individual varies but little, being almost independent of the protein intake. 4. The amount excreted appears to bear a definite relationship to the body-weight, so that large men excrete more than small men, and men excrete more than women. In infants and young children the amount is comparatively small, the adult level not being reached until after the fourteenth or fifteenth year.

G.U. = Gastric ulcer. A.N. = Acute nephritis. C. = Chronic. S. = Subacute. I. = Interstitial. B.p. = Blood pressure.

* CASE 15.—Dismissed with evidence of condition becoming chronic, but fundi and blood pressure normal. One year after onset general condition fairly good. No definite cardiovascular changes. Blood pressure 142/68. Urine showed moderate albuminuria and trace of blood. Creatinine normal.

† CASE 16.—Dismissed with œdema and albuminuria. Blood pressure normal. Slight arteriosclerotic changes in fundi. Œdema disappeared two months after discharge. Two years later showed evidence of chronic nephritis. Anæmic, no œdema, slight cardiac enlargement. No palpable thickening of arteries. Albuminuria +, with granular and hyaline casts. Blood pressure 126/90. Creatinine normal.

‡ CASE 17.—On admission, widespread œdema, albuminuria + +, hæmaturia, abundant casts, chlorides absent. Blood pressure 158/98. Retinal vessels full. Breathless and dazed. Impending uræmia.

§ CASE 18.—On admission, breathless, dimness of vision, bronchitis, albuminuria, slight hæmaturia. Blood pressure 180/110. Threatened uræmia.

Technique of Investigation.

During the past two years I have investigated the creatinine excretion in numerous cases of nephritis. The method I have adopted is as follows.

The urine is collected for 24 hours and measured in cubic centimetres. The estimation, which should be made as soon as possible after the termination of the collecting period, is carried out by Folin's method, using a Duboscq-Hellige colorimeter with a solution of pure potassium bichromate (24·55 g. per litre) as the standard. It is important to note that the

urine must be free from acetone and aceto-acetic acid. The result may be expressed in two ways :—

(1) As the *total amount of creatinine excreted in 24 hours.* Normally in an adult this should lie somewhere between 0·8 and 2 g. and in cases showing a very marked reduction in the output this method of expressing the result is entirely satisfactory. In Cases 26 and 27 (see Table), for example, in which the daily output was 0·17 g. and 0·0372 g. respectively, the figures are so far short of the normal that no further comment is necessary. Both patients were actually dying of chronic nephritis when the estimations were made.

(2) As the *percentage of the normal minimum output.* If 0·8 g. be taken as the normal minimum output, then a patient who excretes that amount in 24 hours will excrete 100 per cent. of the minimum normal. In the same way a total excretion of 1·6 g. will represent 200 per cent. of the minimum normal, while a total excretion of 2 g. (the maximum normal) will represent 250 per cent. of the minimum normal. In the two cases already referred to (Cases 26 and 27), the percentages would be 21·25 and 4·65 respectively. The figures here suggested are no doubt open to criticism. No account is taken of the weight of the patient, but the weight of a nephritic patient may be entirely fallacious when œdema is present, and as the calculations are based on the minimum normal output this objection is not a very real one.

In the Table the results are shown in 27 cases, including two cases of gastric ulcer. The latter are included for the purpose of comparison with nephritic cases. They showed no evidence of renal disease, and, at the time of examination, were on a diet closely approximating in food value to the diet of acute nephritics. Both showed a normal creatinine excretion. Cases 3, 4, 5, 7, 8, 9, and 10 progressed satisfactorily and were dismissed well. Case 6 drifted on to a subacute condition, and after three months' treatment was dismissed with albuminuria and some œdema. His creatinine output was good. He has not been seen again, but two years after he left hospital he was reported to be in fairly good health and working regularly. In Cases 11, 12, 14, 15, 16, and 19 progress was unsatisfactory and showed clinical evidence of the development of a chronic condition. Case 18 is still in hospital. Cases 13, 17, 20, 21, 22, 23, 24, 25, 26, and 27 were regarded as bad. With the exception of No. 24, who has not been traced, all were dead soon after examination.

An analysis of various types of nephritis shows that in acute nephritis the creatinine output may be normal or diminished. In those cases showing a definite diminution the output rises as the acute stage passes off if the case is pursuing a favourable course. If, on the other hand, the clinical features point to the development of a chronic condition, the output shows either a steady decline or a failure to rise to the high level usually found in favourable cases. In subacute nephritis—i.e., large white kidney with persistent œdema and albuminuria—a low creatinine output, though not necessarily of grave prognostic significance at the time of examination, probably indicates serious damage to the kidneys and the early development of cirrhotic changes. In established chronic nephritis, especially in those cases with cardiovascular and eye changes, the creatinine output may be taken as a reliable prognostic guide. In severe cases with impending uræmia the output is excessively low.

The Table includes 9 cases which terminated fatally. In all of these the creatinine output was abnormally low and the prognosis, on purely clinical grounds, was never in doubt. The test described may therefore be regarded as confirmatory, or perhaps even as a measure, of the degree of renal damage, even though it might appear to be superfluous in advanced chronic cases. In early chronic cases, on the other hand, where the clinical features are not sufficiently well developed to allow of an accurate prognosis, it is suggested that the test would be of some help in the endeavour to assess the degree of structural or functional renal damage. The test is one which can be easily and frequently performed, and the results, expressed as percentages of the normal minimum output for adults (and to which the term Creatinine Index might be aptly applied), seem to be of definite prognostic value. It should be borne in mind, however, that nephritis is a disease which demands a wide clinical outlook, that the prognosis of every case must depend primarily on a clear conception of the complete clinical picture, and that, until we have a more extended knowledge of the nature of nephritis, all tests of renal efficiency should be regarded merely as useful adjuncts in clinical investigation.

I have to express my indebtedness to Dr. A. W. Harrington, visiting physician, Glasgow Royal Infirmary (to whom I acted as assistant for some years), for permission to publish the results of this investigation. The cases examined have been under his care in his hospital wards. I have also to thank Dr. D. P. Cuthbertson, biochemist to the Infirmary, for granting facilities for carrying out the urinary examinations in his laboratory and for much helpful advice.

CLINICAL AND LABORATORY NOTES

THE ACTION OF LIVER PREPARATIONS ON DIABETES.

By R. D. Lawrence, M.D. Aberd., M.R.C.P. Lond.,
CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

Blotner and Murphy [1] showed that certain aqueous extracts of liver and their concentrates cause a lowering of the blood-sugar when taken by mouth. They claimed that the extract from one pound of liver had an action on diabetics equivalent to some ten units of insulin. This naturally seemed of practical importance as well as theoretical interest. The results herein recorded, however, fail to confirm their conclusions.

[1] Blotner, H., and Murphy, W. P.: Jour. Amer. Med. Assoc., 1929, xcii., 1332; 1930, xciv., 1812.

As the liver extract which is claimed to be effective in diabetes is different from that used in pernicious anæmia, a special extract was prepared, as described by Blotner and Murphy. This was kindly provided by the British Drug Houses, and Dr. F. H. Carr has sent the following details of the method employed : "Liver taken quickly from recently slaughtered oxen was finely minced with a little water and the hydrogen-ion concentration adjusted to 4·8 with N/1 sulphuric acid. The mixture was kept for 16 hours at 35–40° C., and the clear filtrate removed. This was heated to 80° C. for 30 minutes, and the coagulated material was filtered off, washed with water, drained and dried in vacuo at room temperature ; 11½ kilos of ox liver yielded 6·8 g. of the product." This extract was tested in doses corresponding to one and two pounds of fresh liver (0·3 g. and 0·6 g. extract). As Blotner and Murphy show that the

action of their extract can be observed in three to eight hours, there was no need for prolonged investigation over several weeks.

The experiments were all carried out on a young diabetic man, aged 23, a "pedigree" insulin case. He has had the same diet and insulin, 24 units in the morning, 20 units in the evening, for four years, and has been the test subject for many experiments of this kind. It is usually possible to detect clearly the effect of a change of two units in his dose and always of four units. His blood-sugar fasting is about 0·23 per cent., is reduced to about 0·07 per cent. or 0·09 per cent. five hours after insulin, and rises again to about 0·23 per cent. nine or ten hours after insulin. The corresponding glycosuria is also very regular in its appearance and disappearance at certain hours. The effect of the liver extract was observed on him in two phases: (1) by giving the extract by mouth with the usual injection half an hour before breakfast to see if it produced any unusual hypoglycæmia; and (2) by giving the extract at midday to see if it prevented the usual recurrence of hyperglycæmia after the insulin action wears off in the late afternoon. At first the usual dose recommended by Blotner and Murphy was given, and later double the dose, corresponding to 2 lb. of liver. In not a single experiment was any difference in glycæmia or glycosuria observed from the comparable control days without the extract.

Therefore, on a typical uncomplicated case of diabetes of moderate severity I have been unable to detect any action from the use of a liver extract described as effective in reducing the blood-sugar. No experiments have been carried out on mild cases not requiring insulin, as I believe such experiments are less definite and more liable to error in judging the effect of a remedy on the essential diabetic process.

I wish to thank the British Drug Houses, Ltd., for preparing the special liver extract.

A METHOD OF REDUCING SUPRA-CONDYLAR FRACTURES OF THE HUMERUS.

By R. Y. Paton, M.B. Camb., F.R.C.S. Eng.,

ASSISTANT SURGEON, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL; ORTHOPÆDIC SURGEON, NELSON HOSPITAL, WIMBLEDON, AND PRINCESS LOUISE KENSINGTON HOSPITAL FOR CHILDREN.

Sir Robert Jones's method of reducing supra-condylar fractures of the humerus is as follows:—

"The surgeon should grasp the child's wrist with the right hand and place the left hand around the upper arm, so that the thumb puts pressure on the lower end of the upper fragment, just above the elbow. The forearm should be extended and pulled in order to disengage the lower fragment. When this has been done the forearm should be supinated, and while the pull is maintained the arm should be flexed while the upper fragment of the humerus is pushed back. The arm should be flexed to 30 degrees, or as near 30 degrees as the swelling will allow."[1]

This method gives excellent results in the majority of cases, especially when there is little lateral displacement. In cases where there is much backward and lateral displacement it may fail and an alternative method may be required. The technique to be described may result in successful reduction in cases where open correction seems the only possible solution; it is certainly worth a trial before cutting down.

[1] Practitioner, July, 1930.

The child is anæsthetised and lies on his back. The surgeon stands on the side of the injured limb, which is raised with the humerus vertical, the hand and forearm being allowed to fall flexed towards the chest. The hand is steadied by an assistant or the anæsthetist. The surgeon interlocks his fingers round the flexor aspect of the humerus and so grasps the humerus firmly. The thumbs are placed vertically side by side on the dorsal aspect. Keeping the humeral shaft absolutely steady in the fingers, the surgeon now exerts pressure with his thumbs upwards and forwards on the lower fragment and guides it to its proper position. If the lower fragment is impacted it is disimpacted by increasing the deformity—i.e. extension at the elbow-joint. When there is lateral deviation more pressure is exerted by the appropriate thumb to correct it. The fragment will be felt to move upwards and then slip forwards and engage. The assistant does nothing but maintain the position as it improves—with the forearm supinated—under the surgeon's manipulation. When the surgeon is satisfied, by the relationship of his thumbs to his interlocked fingers, that the reduction is complete, he will find that he has obtained flexion to almost 30 degrees. The flexion is maintained by slinging the wrist under the chin, no splint or other retentive apparatus being necessary.

This method approaches the problem of reduction from above, and has several advantages. The lower fragment of the humerus is controlled by the thumbs and is gradually pressed into position, and its jagged upper extremity does not tear into the fibres of the biceps. The amount of manipulation required is reduced to a minimum and the unconsidered force of a powerful lever is dispensed with. (The chance of damaging nerves during reduction is infinitesimal. The local disturbance is very small, even in cases where considerable œdema and swelling already exist. The risk of ischæmia—fresh hæmorrhages not being commenced—is, therefore, reduced. The lateral displacement is much more easily controlled and corrected. Good hands and strong thumbs may be essential to success in these manipulations, but any surgeon who does much orthopædic work should soon develop these assets.

The method described has been successful in cases where other methods of reduction have failed and open correction has been considered. The presence of much œdema was not found to be an obstacle to reduction.

A CASE OF COR BIVENTRICULARE TRILOCULARE WITH TRANSPOSITION OF VISCERA.

By Stanley Davidson, B.A. Camb., M.D., F.R.C.P. Edin.,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF ABERDEEN; LATE ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH.

Maud Abbot[1] reports only four cases of cor biventriculare triloculare in 850 cases of congenital cardiac disease which she has analysed. Three of the cases died in infancy. In no case is mention made of a complete transposition of abdominal viscera, as was found in the following case:—

The patient, a woman of 27, was admitted to the wards of the Royal Infirmary, Edinburgh, in September, 1928, while they were under my charge during the absence on holiday of Dr. A. Goodall. When first seen by me she was in the last stages of cardiac failure. I am indebted to Dr. H. V

[1] Abbot, Maud: Modern Medicine, 3rd edition, London, 1927.

Thwaites, her family doctor, for a very complete set of notes of her past history, of which a summary is appended.

HISTORY OF THE CASE.

The patient was born in 1901, and was one of a family of three; the first child lived for only 12 hours but the second was a healthy male. No difficulty was encountered during the birth of the patient, which was normal. She was fed on the breast. She began to walk and talk at the usual age, was clever at school, was always active, and never suffered from dyspnœa until after an attack of measles at the age of 9. This was the only infectious disease from which she suffered. After this attack she was apt to be breathless on slight exertion, but she never had any fainting turns. Her colour was high. From the age of 10 to 15 years, while still at school, she helped in the work of the house, and at the age of 15 she entered domestic service. In all the situations which she took she was hard worked, and though she was often breathless and occasionally had to spend a day in bed, she was never sufficiently ill to have to give up work and return home. She carried on her domestic service up to the age of 23, when she began to have fainting turns. These turns came on by day or by night, and were not always related to exercise; they frequently occurred after meals. They were characterised by sudden onset, nausea, palpitation, breathlessness, a feeling of choking and, in some cases, by unconsciousness. Many of them passed off suddenly—within half an hour.

On examination in 1924, at the age of 23, a systolic murmur was heard all over the præcordia, which was not conducted upwards from the aortic arch nor outwards from the mitral area. The point of maximum intensity was over the fourth costal cartilage at the edge of the sternum. Percussion of the left border of the heart revealed no dilatation, nor was the liver palpable. During the next three years she had numerous similar paroxysmal attacks. Some came on when at rest, and others after exertion. She was sent to the Royal Infirmary for examination, and the physician who saw her reported that a loud systolic murmur was present, best heard in the tricuspid and pulmonary areas, and that the red blood count showed the presence of a polycythæmia of 8,000,000. From the history that since early childhood the patient had had a high colour, and had been breathless on exertion, a diagnosis of congenital cardiac disease was made. No clubbing of the fingers was present—a point of some interest with such a long history.

Between 1925 and 1927 the patient returned to domestic service for periods of several months, but was always short of breath after exercise and on many occasions had to give up work for attacks of acute heart failure. The attacks started suddenly with intense dyspnœa, threatened syncope, and vomiting. The pulse-rate rose to 150–200 per minute, and on many occasions was completely irregular, many of the beats failing to come through to the radial pulse. The nature of the paroxysmal attacks of rapid pulse-rate was never definitely settled, as no electrocardiographic tracing was obtained, but it was presumed that they were paroxysmal attacks of auricular fibrillation because of the gross irregularity of the pulse. While many of these attacks stopped within a short period as suddenly as they started, a number of them went on for some days, and the patient remained in bed and was treated with digitalis.

In November, 1927, she went back to work again, but returned home eight months later in a very exhausted condition, with a history of having had paroxysmal attacks of heart failure, of the type already described, almost every day for a week. She was given digitalis and improved slightly, but after two months' treatment further signs of serious heart failure appeared. On August 10th, 1928, a hard troublesome cough began, and slight œdema of the ankles was first noticed. The œdema spread to the feet, the cough got worse, and by August 29th the œdema was generalised and she had pain in the left side at the back, with impairment of the percussion note over the lung and distant breath sounds. She was admitted to the wards of the Royal Infirmary, and when first seen by me was suffering from marked orthopnœa, and gross œdema was present in the legs and back. Examination of the lungs revealed signs of chronic venous congestion, the liver was just palpable below the costal margin, and the patient had a distinct icteric tint. The face showed none of the blue coloration believed to be so characteristic of congenital heart disease, nor was there any clubbing of the fingers. The urinary output was low, albumin was present, and in spite of digitalis treatment the cardiac condition failed to respond and the patient died on Sept. 29th, 1928, aged 27, in a water-logged condition.

POST-MORTEM NOTES.

The anatomical and pathological observations given below were made by Dr. J. Whittaker, who, at the time of the patient's death, was clinical tutor in the wards of the Royal Infirmary and assistant in the Department of Anatomy at the University of Edinburgh.

The body was that of a fairly well-developed, well-nourished female. There was general anasarca, and the skin was slightly jaundiced. Post-mortem lividity and rigidity were present. The heart was greatly enlarged.

On opening up the auricles posteriorly, the septum between the two was found to be deficient. The only indication of a division into the separate cavities was a strong band of muscle which merged above into the roof of the auricles and below into the floor, being connected in the middle of its extent by a thin muscle strip to the anterior wall of the auricles. Hence two openings were formed anterior to this partial septum; the one above, the other below the thin horizontal band. The upper opening served as a communication between the left pulmonary vein and that portion of the large auricular cavity which represented the right auricle, the two left pulmonary veins having joined together to form a single trunk. The lower opening formed a further communication between the right and left auricles. The right pulmonary veins, two in number, opened separately into the upper part of the right auricle, the anterior and upper vein being large, the posterior and lower very small. The innominate veins also pursued an abnormal course. The left innominate vein, which was of normal diameter, ran down the left side of the œsophagus and, joining with the left superior intercostal vein, opened into the left auricle. The right innominate vein was joined by the azygos vein to form a short superior vena cava. The inferior vena cava, a large trunk, opened into the lower part of the auricular cavity to the left side of the partial septum.

Hence the openings into the cavity which served as a right auricle were the four pulmonary veins and the short superior vena cava; also there was the coronary sinus. Moreover, into that cavity, which was homologous with the left auricle, opened the left innominate vein and the inferior vena cava. There was, therefore, no superior vena cava. The right auriculo-ventricular valve was guarded by three cusps, one posterior and two anterior.

The musculature of the right ventricle was very thick and corresponded in appearance to that of a normal left ventricle. There were three papillary muscles; two anterior, one arising from the anterior wall and one from the inter-ventricular septum; one posterior, from the posterior wall. The chordæ tendineæ from the posterior papillary were inserted into the sides of the posterior cusp and right anterior cusp.

The aorta arose from that ventricle which was situated in the right side of the heart. It arched over the right branch of the pulmonary artery and over the right bronchus, and passed down the right side of the œsophagus. The pulmonary artery came from the left ventricle. The ventricular septum was complete, and the aorta and pulmonary artery were quite separate. The origin and distribution of all branches of the aorta, both thoracic and abdominal, was a mirror image of the normal. This was to be expected, since a complete transposition of the viscera was present. The inferior vena cava and its tributaries presented the same phenomenon, and the lungs were transposed. Thus the left lung had three lobes and the right lung two, and the arrangement of the structures at the hilum from above downwards on each side was correspondingly reversed.

From the pathological point of view there is little to state. There was a slight excess of straw-coloured fluid in the pericardial sac. There were milk spots at the back of both ventricles and one on the tricuspid valve—i.e., the valve guarding the anterior surface of the left ventricle. The right auriculo-ventricular opening was considerably thickened, although there were no vegetations present.

DISCUSSION.

The essential features of this case may be summarised as follows: (1) an absence of the inter-auricular septum; (2) transposition of the great venous and arterial trunks, and a mirror-picture dextra-cardia; and (3) transposition of the thoracic and abdominal viscera.

The absence of cyanosis, in spite of such a marked congenital defect, might appear remarkable, but Maud Abbot states that the absence of the inter-auricular septum does not itself produce cyanosis, unless associated with a maldevelopment of the pulmonary veins. The association is lacking in this case. The fact that a person with such remarkable anatomical anomalies could lead an active life for 27 years warrants the publication of this individual case.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF ODONTOLOGY.

AT a meeting of this Section held on Nov. 24th the chair was taken by Mr. C. SCHILLING, the President.

Dr. J. F. VENABLES read a paper on

The Teeth and the Stomach

by Dr. A. F. HURST. The normal man, he said, need swallow nothing that was not suitable in its mechanical and thermal properties for the stomach to deal with. Few people, however, used their masticatory mechanism adequately and the gastric juice had to deal with chemical and thermal irritants, while the churning action tried to make up for lack of chewing, and the hydrochloric acid destroyed infected material from an unhealthy mouth. Thus the delicate and vitally important intestinal mucosa had not to deal with irritants provided there was a healthy stomach. When the stomach was ill-treated by bad use of the first line of defence it was unlikely to suffer unless its owner were one of the 10 per cent. with deficient hydrochloric acid secretion; then chronic gastritis with achlorhydria would result. Thereafter the stomach failed to protect the duodenum, and bacteria flooded it, both from the mouth and from the colon. This infection was the chief, though probably not the only reason of the association of achlorhydria with so many diseases. Thus pyorrhœa and inadequate chewing played an indirect part in a very large number of secondary diseases. The glossitis of Addison's anæmia and subacute combined degeneration of the cord was very rare in the absence of achlorhydria; many patients attributed this sore tongue to their teeth, and dentists might make an early diagnosis.

The 10 per cent. of people with natural hyperchlorhydria were well protected. According to Rosenow a streptococcus could be isolated from the teeth of most people with gastric and duodenal ulcer, but his work had not received much support. Nevertheless dental disease played an undoubted part in ulceration and its treatment was an essential part of the treatment of ulcer. Much could be done by dental hygiene to prevent the swallowing of infected material, and any bad teeth should be removed as soon as occult blood had disappeared from the stools. During convalescence pyorrhœa should be thoroughly treated; the patient should see his dentist every three months. There was much evidence that cancer of the stomach was never a primary disease, so that the treatment of chronic gastritis or ulcer might be a method of preventing malignant disease.

Abdominal operations should be postponed until dental disease had been treated, as they caused a reflex achlorhydria, with the result that swallowed organisms were not destroyed; this might be the cause of post-operative ulcers.

Thus dentists could do much to prevent many kinds of gastro-intestinal disease directly and other forms of disease indirectly.

Mr. G. J. TURNER asked what value was to be placed on the mastication of meat. He thought it was the food that least needed chewing, while stodgy carbohydrates needed most. Was it possible for bacteria to pass through a normal gastric juice? Did not swallowing foul matter from adenoids or pyorrhœa inhibit the secretion of juice? It had been said that recurrence of duodenal ulcer was entirely due to lack of dental treatment after operation. He was glad to hear pyorrhœa regarded so seriously; he thought a mouth should be thoroughly cleaned every month, for decomposition started again within 24 hours of cleansing.

Mr. S. A. RIDDETT asked how frequently the Addisonian anæmia syndrome might be expected to appear in ordinary practice.

Dr. F STOLKIND said that every healthy tooth was worth £200 in American health insurance; the companies saw the connexion between a healthy mouth, a good digestion, and long expectation of life. The Russian peasants knew nothing of cleaning the teeth, but their good mastication kept their teeth in excellent condition. People in civilised life had no time for mastication, and soft food had been substituted for it; the result was indigestion, especially constipation. Careful mastication by good teeth had great therapeutic value in gastro-intestinal disease, but artificial teeth could not replace real teeth. Edentulous patients suffered less from indigestion if they ate without their teeth.

Dr. HUGH STANNUS asked if any work had been done on what proportion of persons masticated properly. Animal tissue was digested best if not masticated, and the vomit of a mixed meal revealed amazing masses of carbohydrate but little animal tissue.

Dr. H. W. KENSHOLE remarked that the gastric acidity decreased between meals, and infected material could pass through more easily at that time. When the acid was secreted into the gastric juice there was a relative alkalinity of the blood. Could achlorhydria be associated with acidosis?

Mr. ALFRED BAYLISS asked whether any definite dental picture and reaction of the saliva were associated with achlorhydria. He had noted a definite rise in alkalinity of the saliva around the period of a meal.

The PRESIDENT recalled the case of a man who had no two teeth meeting in his jaws; he had kept healthy by living on meat, especially steak.

Mr. ARTHUR BULLEID asked if the conservative treatment of pyorrhœa could be supported by the administration of hydrochloric acid to avert extraction.

Mr. E. PUGH asked at what period bad teeth should be removed in ulcer cases, whether the socket should be curetted, and if a vaccine were recommended.

Dr. VENABLES agreed that the mastication of meat was far less important than that of other forms of food. He did not think that a person with a normal secretion was likely to pass bacteria through the stomach, even between meals. That bacteria did not reach the duodenum was proved by the hundreds of sterile duodenal specimens that had been obtained. The Hunterian glossitis was not common, but once seen was very easily recognised. He could not say what proportion of people efficiently masticated their food. People with achlorhydria had no abnormal hydrogen-ion concentration in the blood and there was no definite dental picture that could be associated with their condition, except that a mouth pouring with pus probably indicated achlorhydria. An early case of pyorrhœa might have hyperchlorhydria, and it would not be safe to give hydrochloric acid without a test-meal. Dead teeth in ulcer cases were extracted after all symptoms had disappeared but before the

patient was taken off a diet treatment. Curettage was advised, but vaccines had not proved satisfactory.

Mr. J. LEWIN PAYNE reported a case of

Replantation.

He showed a patient in whom two replanted teeth had remained for nine years. She had had a fibroid epulis and the two central incisors removed at Guy's Hospital, and the teeth had been replaced after curettage of the alveolus and removal of the pulps. They had been held in place by a metal splint for four weeks, after which the teeth had been firm and the gums healthy. Four years later, although she had made no complaint, an X ray had shown some rarefaction at the roots and there had been some pocketing. She had refused extraction at the time but had finally had the teeth removed. Mr. Payne thought that replantation might be justified in young healthy patients with no previous periodontitis.

In reply to questions, he said that there had been no systemic infection during the period so far as he knew, and that he did not think there would have been any hope of getting pulp reunion in this case though it happened in younger cases.

Mr. W. A. BULLEID described a case in which the replanted incisor had been removed for periodontitis and had remained satisfactory for at least 13 years.

Mr. TURNER said that he had known replanted central incisors last 25 years, and that accidental cases certainly had a good chance.

The PRESIDENT spoke of amateur replantations which were often firm enough but caused trouble by bad alignment.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A MEETING of this Section was held on Oct. 31st, when Dr. J. LAIT gave a presidential address on some aspects of

Splenomegaly.

In certain cases, he said, a diagnosis could readily be reached by complete blood examination; this group included leukæmia, Addison's anæmia, leukanæmia, von Jaksch's anæmia, erythræmia, acholuric jaundice, and the rare condition of Niemann's disease. In certain reticulo-endothelial diseases the splenomegaly often dominated the clinical picture. Abnormal metabolism or storage of lipoid by the reticulo-endothelial system resulted in the clinical entities of Gaucher's disease and Niemann's disease. Dr. Lait postulated congenital dysfunction of the reticulo-endothelial blood-forming and blood-destroying tissue as the ætiological factors in acholuric jaundice and erythræmia respectively. The parasites of kala-azar were so often found exclusively in the cells of the reticulo-endothelial system, that kala-azar could be called a disease of reticulo-endothelium. Piney's conception of Hodgkin's disease as a reticulo-endotheliosis was an advance. Although the cause still remained obscure, its result was defined. Finally Dr. Lait discussed the evolution of the infection hypothesis of the idiopathic splenomegalies, especially splenic anæmia and Banti's disease, and spoke of Gibson's view that a mycotic organism was responsible for these diseases. He demonstrated specimens of spleen showing Gandy-Gamna nodules in which the organisms have been found, and showed photomicrographs of sections from spleens in which mycelium-like threads were clearly visible. He had also identified Gandy-Gamna nodules in a syphilitic spleen and in a spleen from a case of myelogenous leukæmia.

Dr. T. G. MOORHEAD said he was interested to hear the President's statement that Banti's disease was never hereditary, for the very case on which the President based some of his remarks was that of a boy whose father had suffered from the disease. Dr. Moorhead thought that far too little was known about either the incidence or ætiology of many splenomegalic diseases to justify dogmatic statements. For example, at one time acholuric jaundice was looked upon as purely familial, but later it was recognised that non-familial cases were met with. In the same way Banti's disease was generally regarded as non-familial, but his own experience led him to believe that a familial variety would be recognised before long. As regards blood examinations, he had recently seen in consultation with Dr. William Boxwell a patient suffering from lymphatic leukæmia with some splenic enlargement. An unusual feature of her blood was that the red corpuscles agglutinated almost instantaneously when blood was drawn, so that it was impossible to make films for examination.

Dr. E. T. FREEMAN said he had seen two similar cases—one a case of malignant disease and the other a case of septicæmia in which transfusion was intended but could not be carried out because rapid agglutination prevented a test of the blood.

Dr. R. H. MICKS said that he also had come across two cases in which agglutination had taken place rapidly, one of them a case of pernicious anæmia.

Dr. J. W. BIGGER said he hesitated to label anything as a mycosis. In a recent case he thought he saw a mycelium, but later became convinced that he was looking at the remains of various forms of tissue from which the cells had fallen away and died. Gandy-Gamna organisms were found in a great variety of cases of enlarged spleen, and he could not see how they could possibly be the cause of all the splenic conditions in which they were found. He personally thought that these organisms were only invaders. It was necessary to realise that organisms did invade the body constantly. The blood of the patient mentioned by Dr. Moorhead, whom he had seen with Dr. Boxwell agglutinated at once. He (Dr. Bigger) found that the serum of this patient was capable of agglutinating all types of human blood. As the patient was still alive, agglutination could not be going on in her body, therefore he thought it could only occur in the cold, and he thought this case was parallel to cases of paroxysmal hæmoglobinuria.

Dr. A. R. PARSONS said that Osler looked on splenic anæmia as the first stage of Banti's disease. The speaker was not an advocate of surgery in cases of enlargement of the spleen. He mentioned a case of familial icterus which he had first seen in 1908, and in which he had given medical treatment to the patients, father and son, and they were both quite well still.

Dr. J. T. WIGHAM said it was sometimes stated that patients with Banti's disease usually had quite a small spleen, while patients with splenic anæmia had a large one. He personally thought that this was of no importance, and said that malarial spleens which were big at first got quite small afterwards. He thought the President had not put forward any argument in his paper which would enable one to distinguish between Banti's disease and splenic anæmia.

PUBLIC HEALTH CONGRESS.

THIS congress of municipal associations interested in public health administration, after its formal opening by the Minister of Health on Nov. 17th, was continued throughout the week. We reported in our last issue Sir Arthur Newsholme's address on Medicine and the State. At the morning session on Nov. 20th the chair was taken by Mr. L. G. BROCK, and Dr. THOMAS BEATON opened a discussion on some practical aspects of the

Mental Health Problem.

He sketched the provision made for mental patients in the past and emphasised the lack of any facilities for treatment in the early stages. The work of the psychiatrist, he said, was very much done in the dark, and people did not want to talk of it. He described the three classes of patient—voluntary, non-volitional, and involuntary—and the main principles of the Mental Treatment Act, 1930. The new service, if it was to operate efficiently, must be under experienced guidance, and must be so organised as to give the patient confidence and encouragement. The less the contact with the machinery of officialdom the better. The out-patient clinic should be the first consideration, and should preferably be part of the work of the local general hospital, and under the direction of the medical superintendent of the local mental hospital. Its scope should include mental deficiency, mental and functional nervous disorder, and organic nervous disease. Work of this kind would do more to undermine the old dread of "asylums" than any amount of propaganda, and the clinic should become a centre from which help might be anticipated for any kind of difficulty arising out of maladjustment to life and erratic behaviour. A social service was essential and could be provided by the local Voluntary Association for Mental Welfare, which could serve as a buffer between the patient and his relatives or officialdom. In-patient treatment for voluntary and non-volitional cases could be provided in general hospitals or reception blocks of mental hospitals, but often some new building or modification of existing buildings would be required. More use should be made of convalescent homes. Special mental hospitals and convalescent homes might reasonably be expected to become self-supporting in the course of a few years.

Dr. D. BREWER urged the importance of eliminating the receiving officer, and said that the department of the medical officer of health had now full power to deal with the problem. He believed that ratepayers were more enthusiastic for social measures of this kind than for economy.

Councillor Mrs. SAUNDERS pleaded the case of the mentally affected child in a private school, and Dr. W. A. POTTS urged the importance of the mental breakdown which followed a mild infectious illness after the patient believed that he had recovered. Mr. SCOTT (secretary, Bucks Mental Hospital) asked if the coöperation of the doctors could be assured, and the CHAIRMAN replied that he need have no fear on that score. Dr. H. R. L. ALLOTT suggested that insured persons should all be periodically examined by their doctors and any deficiencies reported to their societies. In this way disasters could be avoided.

Sir HUBERT BOND expressed his agreement with Dr. Beaton, and defended the old Lunacy Acts from the charge of being the sole cause of inadequate treatment in the past. Coöperation with the voluntary hospital was of the first importance, because people would go there. The CHAIRMAN emphasised the importance of social work and referred to its successful organisation in the Hôpital Roussel in France. Miss EVELYN FOX said the workers must be carefully selected and specially trained, so that they could provide the physician with the vital information required for his work. Continuity in the social services was most important; the same worker should deal with a case throughout as far as possible. The success of after-care would be enormously increased if the worker knew the patient in hospital. The work should not be thrust on public health visitors without special training or extra help.

In the afternoon Mrs. HUME PINSENT took the chair and Dr. E. S. LITTELJOHN opened a discussion on the

Social Problem of Mental Deficiency.

He briefly sketched the history of the training and care of defectives and described a modern colony emphasising the happiness and usefulness of a defective under proper care to-day. A certain small percentage were temperamentally unstable or delinquent and should be treated apart, but the majority—85 to 90 per cent.—improved enormously in a suitable environment. During the last nine years inmates had been allowed away from the Manor House colony unattended on 34,000 occasions, yet there had not been a single complaint of behaviour. This showed what supervision and training could do. Mental defectives were a-moral but not immoral; the sexes mixed freely in a colony, but it never occurred to them to be immoral. In a bad environment, however, their suggestibility and facility might cause them to fall. The cost of dealing with the social evils they caused when at liberty was far greater than that of keeping them in colonies. He ran through the features of the Wood report and its recommendations, and then discussed the causation of mental deficiency. Probably about 80 per cent. of it, he said, was due to inheritance but only about 7 per cent. of defectives had a defective parent; it was carried by the apparently normal and related to adverse factors, such as poisons and injury. Further research was urgently needed. Considerable improvement was to be expected from recent Acts of Parliament and much might be done by an enlightened press.

Sir JAMES HINCHCLIFFE said that the expense involved in providing education for all the mentally defective was quite beyond the means of the country at present. His county had tried to get mental deficiency excluded from the Local Government Act 1929, as the treatment was still in its infancy. He advocated sterilisation. Dr. F. D. TURNER expressed agreement with Dr. Litteljohn and sketched the stages in the development of the treatment of mental deficients. At one time we had expected to cure them all; an alarmist stage had followed, coming from America after the publication of family histories, and now we were in a socialisation or resocialisation stage. Mental deficiency institutions in the past had been apt to stagnate; in future they must be more fluid and widely distributed, with their main object the passage of the defective back into the world for the low-grade but essential work of which he was capable. He must leave under licence and must not be discharged. Dr. A. W. SIKES agreed with Dr. Turner and declared that true economy lay in putting a stop to the increase of mental defect. Very little was known about the whole problem at present. Dr. J. A. FAIRER did not think there were so many defectives in the country as was often claimed; to

high a standard might be set. The CHAIRMAN emphasised the gravity of the problem, and said that more defectives might be ascertained if schoolteachers learned more about them.

On Friday morning the chair was taken by Mr. WALTER HEDLEY, K.C., and Dr. C. P. BLACKER opened a discussion on

Sterilisation of the Unfit.

The Eugenics Society, he said, did not hold that sterilisation should be applied indiscriminately or was in any way a panacea which would abolish defect or that could be an alternative to segregation; it was essentially an auxiliary to segregation. They thought it was applicable to certified defectives, recovered insane, and persons suffering from grave inheritable physical defect. The society had proposed that permissive sterilisation should be carried out on those regarded as suitable by responsible authority. The consent of the individual, the guardian, the spouse (if available), and of the Board of Control was to be obtained. The cautious attitude of the Board of Control was a guarantee that no rash action would be taken. As safeguards to the last category, two independent medical practitioners as well as the operating surgeon would have to give additional consent. The Eugenics Society, therefore, made no ill-considered or far-reaching proposals. Everybody agreed on the simple axiom that it was contrary to public policy that defectives should be allowed to breed. Ignorance of the method of inheritance of mental defect was therefore not a relevant objection to legalising sterilisation. The Board of Control had advocated forbidding the marriage of defectives; the chief object of this measure was to prevent breeding. If we knew enough about inheritance to forbid marriage we knew enough to legalise sterilisation. Legal prohibition of marriage would incite a defective to promiscuity far more efficaciously than sterilisation, for it frustrated two instincts: the sexual and the desire for a stabilised home. Sterilisation could only remove a fear of pregnancy, which of necessity had far less deterrent effect on a defective than on a normal person who was fully aware of the consequences of the actions. It was already legal to sterilise for therapeutic reasons, but the law on eugenic sterilisation was ambiguous and obscure. The operation could be done privately on people who could pay, but not officially; this made it subject to abuse.

Dr. W. F. MENZIES said that there were all shades of opinion in the Royal Medico-Psychological Association, as outside it. If the Eugenics Society were on the left wing of the moderates, the Association might be described as on the right wing. A large body of opinion thought that sterilisation might be made a condition of discharge from colonies or institutions. This would result in a small diminution of defect or "neuronic instability"—say 3 or 4 per cent. There was no evidence that the defective was more fertile than the average man, but everyone agreed that in modern civilisation breeding was taking place from below upwards. In the speaker's personal experience, American opinion was that sterilisation would only touch the fringe of the problem. The real trouble was the carrier. Mental deficiency in a few generations always cured itself. He was not opposed to sterilisation, but did not want his audience to think it would do much good.

THE NEED FOR IMPARTIAL INQUIRY.

Dr. A. F. TREDGOLD pointed out that "unfitness" was much more than mental deficiency. A fit person could earn his living without being a burden on the community and could conform to current standards of behaviour. The most important groups of unfitness were those who constantly ailed, chronic paupers and ne'er-do-wells, habitual criminals and, lastly, the insane and mentally defective. A certain proportion of cases of each type were due directly to environmental conditions, but a very large proportion were the result of inheritance; it was very difficult to distinguish them. Therefore it was quite fallacious to regard unfitness as a clinical entity and to legislate for it in the mass. Mental defectives constituted a serious problem, and in 80 per cent. their condition was due to neuropathic inheritance, but the parental neuropathy was not necessarily—or often—mental deficiency. Sterilisation would not greatly reduce the incidence of defect, although unfortunately there was a strong public belief that it would. Defectives in the upper classes very rarely came from defective parents. Nor would it greatly reduce the cost of defectives to the State; they were ipso facto unable to compete with normal people and any contribution they could make to their own upkeep must be made under sheltered conditions. The best place for the bulk of defectives was the colony; their presence in the nation must always be attended with expense, and they cost less in special institutions than loose among the population.

Propagation by the insane was very much greater than by the defective, and a considerable proportion of their progeny did not come up to normal standard. A far stronger case could be made out for the sterilisation of the insane than for that of the defective; nevertheless many cases of insanity were due to an environmental factor and not to abnormal inheritance. The definition of insanity was made more difficult by the new Act. Nobody would regard sterilisation as suitable for the habitual criminal, but there was much to be said for sterilising chronic paupers if it were possible to distinguish the hereditary cases. The physically inefficient group was responsible for quite as much national expense and deterioration as any other, and in it lay the *fons et origo* of mental deficiency. Here again, however, the trouble lay in distinguishing the hereditary case. Sterilisation was applicable only, therefore, to unfit individuals who could earn their living in the community, whose defect could be shown to be germinal, and whose danger to the race lay in their powers of propagation. The presence in the community of girls known to be sterilised would constitute a danger, as the fear of parenthood did act as a deterrent on young men. No procedure should be embarked on hastily before investigation by a competent and impartial tribunal.

Mr. Alderman LOVSEY (Mental Hospitals Association) said that the man in the street felt that he had not the information he would like on the subject, and demanded an impartial and comprehensive inquiry, preferably through the agency of a Royal Commission. He was bewildered by the abundance of evidence for and against.

Father DAVIS, S.J. (Haythrop College), said that the Catholic point of view had not been officially pronounced, but in his opinion the benefits to be derived from sterilisation would not justify it on rational, ethical, or moral grounds. A man had a natural right to his bodily integrity until he forfeited it by crime; no part of a man's body could be cut off by another man or by the State even for the benefit of others. Voluntary sterilisation was also universally condemned because a man had not the right to dispose of parts of his body except to save the whole.

GENERAL DISCUSSION.

Dr. KJÖLSTAD, who was representing the Norwegian Government, said that the subject was one which was of great interest in Norway.

Dr. W. W. HERBERT said that in time he hoped the biologist would be able to distinguish the carrier from the sound person. He considered that persons discharged from asylums should be warned that they ought not to propagate, should be taught contraceptive methods, and offered sterilisation. An official inquiry was only a way of putting off till to-morrow what we ought to do to-day. The financial question had been stressed, but not the great human suffering to children born doomed to suicide or insanity.

Dr. W. A. POTTS was in favour of sterilisation under proper safeguards, but pointed out the danger involved by the fact that it was being advocated by backward local authorities who hoped it would save them their obvious duty of ascertainment and colony provision. A proper inquiry was needed. Even if sterilisation was only applicable to one-half per cent. of cases, it should be used for them, for every great social improvement began from a small beginning.

The children of a defective mother would never be an asset to the community. Incautious sterilisation of psychotic patients might prevent the continuance of a valuable stock, for mental instability was often closely allied to brilliance.

Councillor Miss PATERSON, J.P., agreed with Dr. Blacker, Dr. Tredgold, and Dr. Potts, but suggested that we were losing valuable stock at present as a result of the limitation of families made necessary by expensive social services such as that of mental deficiency. There was only one real fundamental human right and that was the right of every child to be born with a healthy body and a sound mind. She did not want a Royal Commission; she wanted things done, because children were being born with their birthright taken away.

THE CONGRESS DINNER.

On Wednesday, Nov. 19th, Sir Frederick Willis presided over a dinner to members of the Congress and a large assembly of guests, when a very interesting speech was delivered by Sir Herbert Samuel in proposing the toast of the Public Health Services. Sir Herbert reviewed briefly and clearly the responsibilities of the medical officers in the services, demonstrating clearly the debt which is owed to them by the country. The toast was responded to by Sir Arthur Robinson (secretary to the Ministry of Health), Mr. F. H. C. Wiltshire (town clerk of Birmingham), and Mr. E. S. W. Hart (clerk to the Middlesex County Council). The health of the Chairman was proposed in witty terms by Mr. Alderman A. R. Atkey, J.P., late Lord Mayor of Nottingham. The dinner, which might fairly be styled a banquet, was a great success, and a very large company enjoyed some excellent speaking.

REVIEWS AND NOTICES OF BOOKS

Text-book of the Surgical Dyspepsias.

Second edition. By A. J. WALTON, M.S., M.B., B.Sc. Lond., F.R.C.S. Eng., Surgeon to the London Hospital. London: Edward Arnold and Co. 1930. Pp. 720. 42*s*.

WE welcome a new edition of this book. Its merits always lay in the fact that the author's views are based upon a large experience carefully analysed. In this respect its value is further enhanced, since the number of cases reviewed is greater, and, indeed, assumes considerable proportions. The reader cannot but attach importance to opinions founded on such a firm basis, and, moreover, the consideration given to the writings of other workers in this field of surgery and medicine shows that the author's reading is wide.

The new edition is thoroughly up to date, and its scope is extensive. Of cholecysto-gastrostomy, which has been recently revived for the treatment of chronic gastric ulcer, Mr. Walton has had unfavourable experience; his verdict will doubtless lessen the current enthusiasm for an operation which seems to have little to recommend it. For very large and adherent ulcers gastro-jejunostomy with perhaps a later excision of the ulcer is recommended. We could find no discussion on the place that should be accorded to jejunostomy in such cases. The book is full of statements of paramount interest to the surgeon, but where some of these are not supported by statistics they are open to criticism. For example, it is affirmed that invagination of the duodenum will stop hæmorrhage whether it comes from an ulcer on the anterior or pancreatic wall of this viscus. That it is usually essential to perform a gastro-jejunostomy when operating upon a perforated duodenal ulcer will not be accepted by everybody, but we welcome the warning against too early removal of the drainage-tube. A very valuable contribution is that dealing with reconstruction of the common bile-duct.

This book ranks high in surgical literature. The sustained effort, extending over many years, necessary to its compilation, the careful correlation of personal observations with the experiences of others is an achievement which has put every practising surgeon in debt to the author.

A Manual of Diseases of the Nose and Throat.

Seventh edition. By CORNELIUS G. COAKLEY, A.M., M.D., F.A.C.S., Professor of Laryngology and Otology in the College of Physicians and Surgeons, Columbia University. London: J. and A. Churchill. 1930. Pp. 672. 18*s*.

THE purpose of this book is primarily to provide a compact manual on the nose and throat for the needs of students and practitioners. It begins with a short, perhaps too short, chapter on the anatomy of the region, a still shorter one on physiology, and a longer and far more thorough description of methods of examination. The diseases of the nose, naso-pharynx, pharynx, and larynx are discussed as thoroughly as the conciseness of the style allows.

For the treatment of chronic empyema of the maxillary antrum, Prof. Coakley recommends intranasal opening under local anæsthesia with removal of the anterior half of the inferior turbinal, and finds a more radical operation rarely necessary. In the "radical" operation, for which he does not give the indications, he opens the antrum through the canine fossa, and completely removes the mucous membrane

from every nook and corner, stating that any small shred of mucous membrane left will invariably result in failure to secure healing; he makes no opening into the nose, but packs the cavity with iodoform gauze, renewed every four or five days for a month, and obtains complete obliteration in about three to six months; he does not give reasons for advocating this method, which entails prolonged and disagreeable after-treatment and has long been abandoned by most rhinologists. In the treatment of quinsy he advises that the abscess should be opened by means of a stiff bent probe inserted into the supratonsillar fossa, and does not mention the more usual method of opening through the area of bulging in the palate. The operation for removal of tonsils by dissection is well and carefully described, with a clear account of the author's own well-known slip-knot ligature; for the removal of adenoids he prefers the La Force adenotome. In the chapter on the larynx, the well-defined and important condition of multiple papillomata in children receives no mention; though singer's nodules are said to occur nearer to the posterior than to the anterior portion of the vocal cords, the illustration shows the prominences on the vocal processes.

In the section upon malignant disease, intrinsic growths are classified as primary, and those involving the epiglottis and aryepiglottic folds as secondary to extension from the tongue and pharynx, a classification by no means always in accordance with the facts. In a manual of this size the operations for the removal of malignant laryngeal growths are rightly not described, but, in view of the great importance of early recognition by the practitioner, the symptoms and diagnosis of the early stage of the disease might well be more carefully discussed; thus, it is misleading to mention pain as a symptom unless it is emphasised that it only occurs late in the disease. Again, impairment of mobility of the cord is given in more than one place as a diagnostic sign, whereas it is well known nowadays that this sign implies such deep extension of the growth as to render the prospect of successful removal by laryngofissure very uncertain. Attention to the technique of the operation has so improved the results of laryngectomy in recent years that the statement that "few patients survive the operation" is no longer true.

These details, however, little impair the value of the book, which is deservedly popular.

Investigations, mainly on the Physiological Actions of X-radiations.

Conducted for the Cancer Research Committee of the University of Sydney.

Grenz Ray Therapy.

By GUSTAV BUCKY, M.D. New York: The Macmillan Company. 1930. Pp. 170. 15*s*.

THE collection of papers from the Cancer Research Committee of the University of Sydney shows that a healthy state of activity and inquiry is the outcome of the effort made five years ago at the University to stimulate interest in the actions of radiations upon living matter. The papers of most general interest in this collection are those upon the differential action of X rays. This work has been attempted from several sides, Dr. Moppett's observations being the starting-point for investigations of a physical and chemical character into the part played by certain chemical elements in the cells in this differential action. The 17 original papers included in this volume are all genuine attempts at research in a difficult field.

The book by Dr. Gustav Bucky includes contributions by Dr. Otto Glasser and Dr. Olga Becker-Manheimer. In the section written by Dr. Glasser we learn that "Grenz rays are soft Roentgen rays having wave lengths of from 1 to 3 Angstrom units, and are produced in lithium glass X ray tubes with voltages from 4 to 10 kilovolts." These rays are very easily absorbed by all forms of matter; they have been given the name Grenz by Dr. Bucky because he believes them to form a sort of boundary between ordinary X rays on the one hand, and ultra-violet rays on the other. We do not much care for the name. The terms soft X rays or long wave-length X rays have the advantage that they describe some characteristic of the rays, while the term Grenz indicates a boundary that does not exist. These rays have been used by Dr. Bucky and others in the treatment of a number of diseases, not only diseases of the skin. We gather that the development of this form of therapy has been somewhat chequered, for on page 109 the author says: "But even if a method involves risks, a patient may be willing to take a chance at times if he may thus be rid of a protracted, troublesome disease." He continues: "Thus, it is not logical to dump the child out with the bath and arbitrarily to issue the fiat that a therapeutic method must be abandoned because of certain possible aftermaths." The meaning of this is baffling.

Romance of the British Voluntary Hospital Movement.

By A. DELBERT EVANS and L. G. REDMOND HOWARD. London: Hutchinson and Co. 1930. Pp. 360. 18*s*.

THE "Voluntary Hospital Movement" is a very modern phrase, but the authors of this stout volume, to which Sir W. Arbuthnot Lane contributes an introduction, carry it back to the monasteries regarded as hospitals for the sick, and to the refounding, after the Dissolution, of St. Bartholomew's as solely a curative institution. This is a large field to cover, and, on the whole, the authors cover it adequately. They are naturally much indebted to the late Sir Henry Burdett's monumental "History of Hospitals"; a book of this kind intended for more or less popular use must necessarily be, in the main, a compilation. It will tell the specialist little with which he is not already acquainted, but it should be useful as a compendious book of reference.

There was room for a book which should bring together the facts and arguments relating to the progress of the hospital movement in the modern sphere, and especially since the Great War, and much space is devoted to this side of the subject. Thus we have a sketch of the rise of the specialist hospitals, of the work of the teaching hospitals, the creation of scientific nursing, the place of the poor-law institutions, and a discussion of the technical problems affronting the voluntary hospitals, together with an account of such new methods of support as the Hospital Saving Association and the various developments of contributory schemes. The facts and figures thus brought together afford an impressive view of many sides of a great subject, that which relates to very recent legislation not being ignored. What may be called the modern history side of the subject is, indeed, the most useful part of the

volume, which contains a very large number of small illustrations.

The index is full, but by no means complete. We notice certain slips. "Angelnoth," an Archbishop of Canterbury who is supposed to have been flourishing in 1201, is a prelate unknown to history, and the house of the Society of Apothecaries is not in Pilgrim-street. The statement that "the first cottage hospital" was founded at Cranleigh, in Surrey, in 1859 by Mr. Albert Napper, F.R.C.S., is inaccurate. The Warwick Dispensary and Cottage Hospital was founded in 1823; Frodingham Cottage Hospital, in Lincolnshire, goes back to 1844; that at Ripon to 1850, and that at North Ormesby to 1857. The name of the Founder of THE LANCET is mis-spelt more than once.

Modern Skin Therapy.

By H. D. HALDIN-DAVIS, M.D., M.R.C.P., F.R.C.S., Dermatologist, Royal Free Hospital; Lecturer on Skin Diseases, London School of Medicine for Women. London: Jonathan Cape, Ltd. 1930. Pp. 128. 5*s*.

THERE is much to commend in this handy little manual. A lucid and fluent style and an engaging, if slightly cynical, outlook enliven its pages, and hold the reader's attention closely through all the ten chapters. The selection of subjects has been made with a view to meeting all the simpler requirements of the general practitioner. With those requirements in mind it is unexpected to find a long chapter on lupus, which, as the author himself admits, "is in most cases beyond the resources of any single medical man" (p. 59). The treatments of furunculosis intertrigo, carbuncle, scabies, pediculosis, and that ever-present and much maltreated disease—impetigo—are not entered upon, although they may tax the average therapeutic resources, and require expert advice. All that is worthy of consideration in the genesis and treatment of eczema has been described in plain language, and there is a refreshing absence of complicated formulæ. The author's exceptional experience in the application of X rays in the treatment of tinea tonsurans qualifies him to speak on this subject with particular force, and makes his carefully detailed descriptions of the technique he employs of great value. His last chapter on minor surgery includes an account of carbon dioxide freezing and its indications, electrolysis, and the technique for the injection of varicose veins. It is satisfactory to note that in common with nearly all other authorities, Dr. Haldin-Davis unhesitatingly condemns the X ray treatment of hypertrichosis, and reduces the field and indications for ultra-violet therapy to one of honest if diminished proportions.

Bacterial Metabolism.

By MARJORY STEPHENSON, M.A., Associate of Newnham College, Cambridge; Member of the Scientific Staff of the Medical Research Council. London: Longmans, Green and Co., Ltd. 1930. Pp. 320. 18*s*.

AN outline of the essentials of bacterial metabolism has been lacking in British bacteriological literature, and this volume supplies one. The general arrangement is good. The various chapters deal with fermentation, respiration, growth and nutrition, carbohydrate and protein breakdown, and nitrogen fixation, while there is an extensive bibliography at the end of the book. There is, however, great variation in the lucidity with which different subject are dealt. Many are excellent but a few, like th sections on oxidation, oxidation-reduction potentials and anaerobiosis—these dealing particularly with th work of Miss Stephenson's own school—are discussed in a confused manner. This is mainly due to undu prominence given to isolated and often unconfirme data. Happily the author, usually at the end emerges from the haze with clearer conception, as for example, in her concluding sentence on th respiration of anaerobes, "notwithstanding muc work, however, the main problem of how stric anaerobes live remains unsolved." There are severa omissions, particularly of work done by Britis bacteriologists on anaerobes and hæmophilic bacteria This is doubtless due to the fact that the source o much of the author's information does not refer t British work. We could find no reference to th nature of toxins or their production. Apart fro these defects, Miss Stephenson has succeeded i preparing from a heterogeneous accumulation o bacteriological data a volume which is a usefu summary of the present-day knowledge of bacteria metabolism.

Del Ringiovanire Diatermico.

By Dr. GAETANO ZUCCHI. Milano (132)—Viale Romagna N. 58. Soc. An. Istituto Editoriale Scientifico. Pp. 240.

THE author of this monograph holds the opinion that the changes accompanying old age in men are caused by deficiency in the internal secretions of the testicles, and maintains that these changes can be prevented by applying diathermy to these glands. Believing, as he does, that there is no real kinship between man and the anthropoid apes, Dr. Zucchi believes that Voronoff's transplantation is unscientific. He also criticises Doppler's operation (sympathicolysis of the spermatic artery) as dangerous. He describes some work which he has conducted on the application of diathermy to bull's testicles for the purpose of ascertaining the conductivity of gland tissue of this kind and of devising a suitable technique. In the human testicle he has observed that the senile gland offers a lower resistance to electricity, and that diathermy increases it. He thinks that this increase may serve as a prognostic index of clinical improvement. The benefits which are claimed for testicular diathermy are great. They are said to appear, in some cases, after the first treatment, and in all cases after six to eight applications. The asthenic, the nervous, the irascible and the depressed are said to show best the effects of the treatment. Greater elasticity is said to be observed in the arteries. The author states that testicular diathermy has been successfully combined with hepatic diathermy in enlargement of the liver in immoderate drinkers and that good results follow the former treatment during convalescence after influenza. In aged diabetics the glycosuria is said sometimes to disappear.

Apart from its use in cases of infection of the contents of the scrotum, diathermy has not been systematically applied in this country to the testicles of those who are the subjects of disease—not, at any rate, when the glands are clinically normal. Until the results obtained by Dr. Zucchi have been confirmed by other workers it is likely that English workers will remain sceptical. The electrodes used, which are protected by patents, are described and illustrated. Their cost is stated, and those who subscribe to the monthly journal *Le Indicazioni della Diatermia* can have them at a reduced price.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 29, 1930.

THE NEXT STEP IN MENTAL TREATMENT.

ON Jan. 1st the Mental Treatment Act will come into operation, and with it the facilities for the early treatment of mental disorders which have long been demanded by the medical profession. It is true that Parliament has hedged these facilities with safeguards which have been embodied in the rules framed by the Board of Control. Some of the safeguards will prove vexatious; they are however consequences of the Act and cannot be helped, and if the practitioner is inclined to resent them he must remember they are the price paid for getting the Act on the Statute Book. It is futile now to grieve over the prejudices which caused these limitations, the more so as the Act is a great forward step; for it will benefit persons threatened with mental illness and at the same time make it easier for the practitioner to give advice when called in. Three features of the Act are especially important to medical practitioners: (1) the extension of voluntary means of treatment; (2) the provision of temporary treatment in early cases; (3) the additional protection given to the practitioner himself.

For the first time in this country public mental hospitals will be able to admit persons who apply for treatment at their own request. In most of the institutions receiving private patients able to pay for treatment a larger number are admitted voluntarily than under certificates; this discrimination between rich and poor will now cease. It is unfortunately true that most existing public mental hospitals are already over full, and until more accommodation is provided complete advantage cannot be taken of the Act. Nevertheless, if even a few patients are so received, the fact will have a good effect; it will tend to remove the feeling of detention, and give to the patients generally a better realisation that the hospital is a part of the health service of the community. A stream of voluntary patients will do much to lessen the prejudices that now exist. But the Act goes much further than this: voluntary patients subject to certain regulations can be received in general or special hospitals and nursing homes previously approved by the Board of Control. It may be thought at first sight that there is nothing new in this, that voluntary patients have always been allowed to go where they like, and that the approval by the Board is unnecessary. It should however be recalled that Section 315 of the Lunacy Act, 1890, is not repealed, and that anyone receiving persons of unsound mind for profit is liable to prosecution unless the patient is certified as such. All those who have had the care of persons with threatened mental disease know it is impossible to be sure that patients will not lose self-control or become irresponsible, and the natural and proper desire to do the best for them may frequently mean infringement of this section. In cases such as this the patient may be willing to sign a paper saying he is remaining voluntarily. It is not expressly stated in the new Act that the holders of voluntary patients are exempt from the provisions of Section 315, but the fact of the case having been notified and that the home or house has been approved makes the position sufficiently secure. The requirement that nursing homes receiving voluntary patients should be approved by the Board will have a salutary effect; many existing places of this kind are inadequately staffed and possess few resources for dealing with these difficult cases. There remains one difficulty under the new Act which cannot be ignored: patients and their relatives may object to signing any paper or formally making application for treatment on a voluntary basis. In practice, however, it is rare for the patients fit to be received in this capacity to object when the position is candidly explained. It must not be forgotten that by voluntary patients are meant persons who understand their position and who wish to be treated. Although many of those who will be dealt with under this section are recent early cases, it is not intended to limit voluntary patients in this way. On the contrary, many of them will be persons long subject to milder forms of mental disorder, or liable to relapses, but who possess insight and realise their need of care and treatment.

The section of the Act dealing with temporary patients introduces an entirely new principle in English legal practice and promises to be of great benefit to large numbers of persons. In future it will be possible to obtain treatment for all suffering from recent and even severe mental disorder without formal certification and without any application to a magistrate, provided the patient does not object. He may be utterly confused or delirious, but if for the time being he is "incapable of expressing himself as willing or unwilling to receive treatment" he may be received as a temporary patient in a public mental hospital, a registered hospital, or in any other institution or home approved by the Board of Control for the purpose or into single care with the consent of the Board. The patient may remain under treatment for six months, which may under certain circumstances be extended for another six months. The Act prescribes conditions under which temporary patients can be received, and it is important that practitioners generally should be familiar with them. An application must be made by a relative or other authorised person. The application must be accompanied by two "recommendations" signed by medical practitioners, one of whom should if possible be the usual medical attendant, and the other must be a medical man approved by the Board of Control. In this instance (con-

trary to the procedure under the Lunacy Act) the medical men may act in consultation. These recommendations must state that the patient is suffering from mental illness and is likely to benefit by temporary treatment, and that it is expedient with a view to recovery he should be received for treatment. The prescribed forms for the application and recommendation will be obtainable from law stationers, and it is desirable for medical practitioners to procure these in advance. Hospitals and homes, other than public and registered mental hospitals, receiving voluntary and temporary patients, have to be approved by the Board. There is every reason to believe that a large proportion of recent cases may never be certified and many will recover without having been termed insane. But this happy event will depend a great deal on whether an approved home can be found which is not too costly, and in default of this whether the local authority has accepted its obligations under the Act and made provision for these cases. It is to be feared that in many localities for some time to come this will be inadequate, although the Board have already had several conferences with local authorities and hospital committees urging the necessity for action in this direction. In deciding the principles on which medical practitioners should be approved for the purpose of making recommendations under the Act, the Board have had the assistance of a committee whose chairman is the President of the Royal College of Physicians, and we have recently published a letter from the chairman of the Board pointing out the importance of obtaining a large enough panel of approved medical men to cover the whole country.

There remains the all-important question of the protection given to the practitioner who makes the recommendations. Whilst it is impossible to foresee the ingenuity of lawyers in bringing action against medical men, nor the extent to which members of the medical profession can be persuaded to give evidence against their colleagues, there is good reason to believe that the sixteenth section of the Act will afford a real protection against legal proceedings being brought against practitioners who sign recommendations under this Act or certificates under the Lunacy Acts. This clause came into force with the passing of the Act, and in future the onus of proving want of reasonable care and good faith rests on the plaintiff, and no proceedings can be brought without the leave of the High Court. The effect of this clause should restore to the medical profession that sense of security which will ensure its coöperation in working an Act which is a great step forward in medical practice, for when it is working fully large numbers of persons suffering from mental illness will be treated to recovery without any certificate that they are of unsound mind. The duty of making provision for the treatment of temporary patients will be thrown upon the local authorities. The Act will in fine make it easier to secure early treatment and at the same time will do much to make this treatment adequate.

THE GROUPING OF FILTRABLE VIRUSES.

IT was near the end of the nineteenth century that LOEFFLER and FROSCH set on firm ground the evidence of ultramicroscopic and filtrable parasitic viruses which were pathogenic for animals. The filtrable virus of tobacco mosaic was described in Russian literature by IWANOWSKI in 1892 and was rediscovered by BEIJERINCK in 1898. To these two virus diseases were added in the next 20 years a number connected with plant pathology and some 40 infections of animals. Although outstanding examples of this category were carefully studied between 1898 and 1920, much greater attention has been given to viruses during the last ten years. Fresh members are being constantly added to the group. Some of these—e.g., ectromelia, the gangrenous disease of mice, and psittacosis—have arrived too recently to be included in the seventh volume of the System of Bacteriology[1] published by the Medical Research Council, which deals with some 48 diseases of mammals and birds, of which 21 do not occur in man. The exact number at present known is uncertain, since some are not completely differentiated—e.g., the pock diseases of animals; moreover, the propriety of including certain others—e.g., pleuro-pneumonia of cattle and typhus fever—in the virus category is open to question. An attempted definition and general survey of the whole group is presented by Prof. J. C. G. LEDINGHAM and Dr. W. E. GYE in a valuable introductory chapter in which many of the characteristic features of viruses are discussed, including the types of immunity reaction and the epidemiology.

It must be acknowledged that the members of the group are heterogeneous and held together largely by negative characters which are not universally applicable. Invisibility cannot be accurately attributed to the microbe of pleuro-pneumonia of cattle or the rickettsia of typhus and the elementary bodies of Paschen in vaccinia; while those of Borrel in fowl-pox have considerable claims to be considered as visible particles of the virus. Filtrability of virus, though in some instances of a high order, is now regarded as variable in degree in many instances and is not always a measure of the size of the particles of virus, although filtration through collodion membranes has been made much more exact by the work of BECHHOLD, BARNARD, and ELFORD. The third chief criterion of a virus—i.e., inability to multiply in artificial culture media—does not apply to the agent of pleuro-pneumonia, and the propagation in cultures of tissues which do not themselves show active growth, as in the Maitlands' cultures of vaccinia, indicate that the line of demarcation between growth in dead and living media may not be very sharp. In some diseases provisionally included in the group by analogy a communicable virus has not yet been generally accepted as proven. Amongst these are encephalitis lethargica and the encephalitis following

[1] A System of Bacteriology in Relation to Medicine. Vol. VII. Medical Research Council. London: H.M. Stationery Office. 1930. Pp. 509. £1 1s.

vaccinia and measles. The collection of the whole together in one volume is, however, justified by convenience and usage. The well-known cell inclusions characteristic of some virus diseases—e.g., rabies, variola—are well dealt with and discussed critically in a separate chapter by Dr. R. J. LUDFORD. The volume contains chapters by 28 different authors, most of whom have made experimental study of the subjects of their contributions. Those diseases on which much recent work has been done, such as dog distemper, yellow fever, foot-and-mouth disease, typhus, and vaccinia are given most space. The diseases of lower animals are amongst those which have yielded the chief additions to knowledge of general importance. Even such an item as virus III. of rabbits, with apparently remote relation to human medicine, is shown to take its part in elucidating immunology, cell-inclusions, and methods of culture. The immunity phenomena in virus diseases are treated in the special chapters as well as in the introduction, and the results obtained suggest less difference from those known in diseases due to bacteria than at one time seemed probable. Antibodies which neutralise the virus have been obtained in vaccinia, herpes, foot-and-mouth disease, cattle plague, fowl-pest, swine fever, Borna's disease of horses, poliomyelitis, and in other instances. Formolised or carbolised virus, which is not infective, has been proved to give specific protection in varying degrees, when used as a vaccine, in rabies, foot-and-mouth disease, distemper, fowl-pest and yellow fever.

That the so-called virus diseases present points of contact with many diverse pathological conditions needs no proof. The properties of the infective extracts of the Rous sarcomata are shown by Dr. GYE to resemble closely other viruses, and the resemblance of these tumours to mammalian new growths is well known, though not insisted on in the chapter here cited. The much-contested relations between the strains of *B. proteus* X and the virus in the typhus group of diseases is fairly discussed by Dr. A. FELIX, especially with reference to the new facts in regard to the forms of tropical typhus and sporadic typhus in the United States, though the author's own views are not concealed. The volume closes with a chapter of 44 pages by Dr. F. M. BURNET on the bacteriophage and allied phenomena. He describes and discusses the fascinating and complex results of experiments, but leaves unsettled the question of the parasitic nature of the phage, though admitting that the objections to D'HERELLE'S well-known view of it as a living independent agent are based on general and theoretical considerations rather than on directly opposing facts. Dr. BURNET considers that the therapeutic value of phage is not established except in fowl typhoid but that suggestive results have been obtained in some other diseases. The results claimed by D'HERELLE in cholera are very good but are not unchallenged. A chapter which will be very welcome to animal pathologists is that in which Dr. J. HENDERSON SMITH briefly and clearly describes the position as regards virus diseases of plants. Dr. R. ST. JOHN-BROOKS gives a short account of diseases of insects which are due to viruses. This volume of a great work well fulfils its purpose, providing a critical statement of present knowledge without undue emphasis on the past stages through which progress has passed.

CHANGING SURGERY.

FROM time to time some of the greatest surgeons have expressed a belief that surgery had reached the limits of efficiency as a method of treating disease; and yet as the years pass we cannot be blind to the fact that surgical craft and surgical science have made great strides. The delicacy of technique of the average abdominal surgeon is immeasurably superior to that of his predecessor of 25 years ago. He has recognised that it is vital to conserve every possible drop of blood, to prevent undue exposure of the viscera, to diminish the afferent nocuous nerve stimuli, to avoid the sacrifice of efficiency to speed without prolonging the operation a moment beyond what is absolutely necessary; and the recognition has made it feasible to resect large parts of the stomach and colon almost with impunity even in the aged. This being so, the fact that we have no knowledge of the future, no vision of the direction in which craftsmanship may advance, does not justify us in predicting that no change for the better can or will take place. Unforeseen technical advances in collateral sciences can often be adapted for use in surgery. A rapidly alternating diathermy current has rendered possible the ablation of certain brain tumours which a few years back were considered inoperable, as their removal was liable to be accompanied by uncontrollable hæmorrhage. The diathermy cautery has made vastly more simple and safe the extirpation of tumours in the tonsillar region. We need not suppose that the technical side of surgery has reached finality.

Nevertheless Mr. C. H. FAGGE has done well to call attention in a presidential address[1] to one important factor in limiting the field of surgery—namely, the small power of repair of specialised tissue. So long as the repair of a wound is due to proliferation of fibrous tissue an impassable barrier of scar tissue will result; thus the best we can do to cure a hernia is to leave a scar where actually contractile muscle should be, and, because of the small power of regeneration of organs and tissues, surgery largely consists in the ablation of diseased parts of the body. Surgery is, in fact, a mutilating method of treatment, for from its very nature surgery is often called upon only when treatment short of removal of the offending part has failed. Medicine is ever searching to anticipate and render unnecessary the use of the knife; every thoughtful surgeon is aware that his science is an ephemeral thing, bound to give way to less violent measures with the advance of knowledge. It is a welcome portent that such realisation is becoming more general on all sides; yet the natural limitations of surgery are not perhaps so strict as Mr. FAGGE would have us believe.

[1] THE LANCET, Nov. 15th, p. 1072.

Elastic fibres will penetrate a scar, epithelium regenerates, many large gastric ulcers heal with so much reconstitution of the stomach wall that their former situation becomes almost impossible to perceive post mortem. In other mammals large portions of muscular tissue have been removed and the muscles have regained their normal size. Motor nerves which have been divided and implanted into muscle have been observed to form new end-plates. The parietal loculi of the common bile-duct have hypertrophied after cholecystectomy to the extent of giving the animal a new gall-bladder as far as function goes. It cannot be denied that regeneration will take place in the kidneys. May we not still hope that, as the result of some new discovery, the fibrous barrier we now obtain in the most aseptic wound will be reduced to a vanishing-point, and ultimately cease to be a barrier at all?

Meanwhile it is all to the good that the limitations of surgery in its present stage of development should be fully realised. The prevalent tendency to restrict the extent of surgical intervention is also good, for the safety and ease with which the surgeon has learnt to remove organs or large portions of them has sometimes led to too radical an outlook. New conceptions arising from more intimate knowledge of disease have restricted the operations of surgery in many septic affections such as acute osteomyelitis, cellulitis, carbuncle. We are entering, in Lord MOYNIHAN'S words, the era of physiological repair by the craft of surgery. Diligent search is being made to substitute some method less radical than cholecystectomy or partial gastrectomy for cholecystitis or gastric ulcer. It is in such studies that surgery advances and technique becomes finer, so that it may be used to greater advantage on the fewer occasions when intervention is necessary—witness especially the progress in thoracic and cranial surgery. In the future no doubt the number of operations will lessen, while the field of surgery will enlarge so as to include what are now regarded as medical diseases. It may be that the present-day distinction between physician and surgeon will disappear, and one individual will combine the knowledge and technical skill of both, to the great benefit of the healing art. In neurology this has already happened. In the case of the organs of special sense it has always existed.

ANNOTATIONS

THE EASTMAN DENTAL CLINIC.

THE opening of the Eastman Dental Clinic on Wednesday of last week is an important event in the record of the efforts made to provide for the dental needs of the children of London. For a long time the only institutions available for the care of children's teeth other than extractions were the dental hospitals, and if time and distance had not limited the attendance they would have been overcrowded. The institution of a large number of clinics in London and its suburbs by the London County Council has made conservative dentistry accessible to large numbers of children, but as the scheme is far from being comprehensive or complete, the important work of treatment of defective growth of the jaws and abnormalities in position of the teeth is scarcely attempted, and these conditions, together with the treatment of diseases of the gums and some surgical affections of the jaws, form a very valuable part of the work of the special dental hospital. Mr. Eastman's object is to demonstrate, in a particular area, the beneficial effects on health of thorough and complete preventive and remedial treatment of the mouth and teeth from the earliest years. For this purpose the sumptuous building and equipment generously provided by Mr. Eastman are more than adequate, and the maintenance has been guaranteed by Lord Riddell and Sir Albert Levy, the chairman and honorary treasurer of the Royal Free Hospital, which the new building adjoins, and with which it is closely associated as regards management and contact. The orthodontic department is to be a special feature, and will go far to meet a growing demand for the treatment of the various forms of abnormal jaw development, which are more intimately connected with general health than is sometimes appreciated. Further possible developments of the clinic leap to the mind. Its association with the Royal Free Hospital suggests a school for the training of women dentists, but for that purpose certainly a child clientèle only would not be adequate. For the training of dental nurses for employment in school clinics throughout the country the institution offers good facilities and the employment of such assistants to school dentists, with strict limitation of function, might well be more extensive than it is; but until the demand develops it would obviously be unwise to train more than can be easily absorbed. Another possibility is research, for which there will clearly be ample accommodation and equipment, and probably clinical material which it would be a pity to waste.

RESEARCH ON THE COMMON COLD.

EARLY in 1928 the John J. Abel fund of $195,000 was established in the medical school of Johns Hopkins University for research into the cause of the common cold. The first definite results from this research are reported in the current proceedings of the Society for Experimental Biology and Medicine.[1] Healthy young women volunteers were secured for the experiment. They were isolated with great care from all chance infection. The experiments, moreover, were carried out in the months of June and July, 1930, when the incidence of colds in Baltimore was at a low level. Nasopharyngeal washings were taken from persons who were in the first 48 hours of a common cold infection. Half of each washing was put through a Berkefeld V candle and in each case the filtrate contained filter-passing anaerobes. The other half was filtered either through a Berkefeld W candle or an improved Seitz filter, when all attempts to demonstrate micro-organisms, either aerobic or anaerobic, in these filtrates failed. The experimental subjects were inoculated intranasally and the pharynx swabbed with small quantities of the same filtrate. In the first group of ten volunteers half received Berkefeld V filtrate and half Seitz filtrate. Two subjects in

[1] Long, Perrin H., and Doull, James A.: Etiology of Acute Upper Respiratory Infection (Common Cold).

each group developed colds. From one of the latter serial passages were made through Seitz filtrates to two other volunteers. In another experiment three successful transmissions were made in series through Seitz filtrates and a fourth passage was made through a Berkefeld W filtrate. These observations confirm and extend previous work, tending to prove that the infection of the common cold is due to a filter-passing virus incapable of growing on any known culture material.

THE CAUSES OF HOOKWORM ANÆMIA.

AN adequate answer to the question of what causes hookworm anæmia has been brought nearer through independent investigations by A. J. Huart of Leiden,[1] and by F. Fülleborn and W. Kikuth of Hamburg.[2] Huart infected dogs with very many larvæ of *Ancylostoma caninum* and *A. braziliense*. Blood appeared in the fæces on the ninth day, sometimes amounting to a bloody diarrhœa; while after death the intestinal contents varied from a blood-stained mucus to large amounts of clotted blood with the underlying mucosa sown with bites. Whether blood was found in the hookworms themselves depended on the interval between the death of the host and the examination. If the latter was delayed the worms were free from blood; if it was made immediately after death the great majority of them contained it. Now G. H. Whipple showed over 20 years ago that a blood-filled hookworm placed in water could be watched rapidly expelling blood, so that whether in Huart's dogs the intestinal blood had mainly been swallowed and promptly wasted by the worms, or had mainly come from their abandoned and oozing bites, is immaterial for the present purpose. In these grave hookworm anæmias, produced by as many as 3000 worms in young dogs of 3 kg., there was severe bleeding into the intestinal lumen. How severe such bleeding may be is shown in the case of one of the Hamburg dogs which died of an acute hookworm anæmia due to *A. caninum*. Its bowels had not been opened for three days. The iron found in its intestinal contents corresponded to 455 g. of the impoverished blood then in its vessels, or to one-eleventh of its body-weight. This presumably represents the drain produced by 1100 worms in three days. There is, then, no question that in these acute hookworm anæmias bleeding occurs into the intestine in great quantity. To conclude that it does not occur in chronic cases is unwarranted. It is noteworthy that viewed as food for the worms the whole of this intestinal hæmoglobin was sheer waste. Clayton Lane has, however, found iron in the intestinal wall and body wall of the hookworms of man, so that, in addition to wasting hæmoglobin, they use it. Indeed, the food required by rapidly growing worms and by adult females laying 6000 to 10,000 eggs daily must be considerable, and it may confidently be concluded that hæmoglobin forms part of it. Blood is used as well as extravagantly wasted by the worms.

The Hamburg work, moreover, showed abundance of pigment in spleen and bone-marrow, the liver being unmentioned in this respect; and although in this instance no iron could be found in the liver, the pigment found in spleen and marrow must have been derived from hæmoglobin just as malaria pigment is so derived. In malaria, another great cause of anæmia, there is destruction of red corpuscles in the circulation. Do hookworms produce a toxin which destroys red corpuscles in the circulation? That hookworms do in fact produce toxins is shown partly by the eosinophilia which normally accompanies their presence, and partly by the intense degeneration with casting of the epithelium found by Hoeppli of Hamburg in the convoluted tubes of the kidney of dogs in acute hookworm infection. As to what particular toxins the worm produces, evidence steadily accumulates that anticoagulins are present in its anterior part—namely, that part containing the large glands which open in or close to the mouth. This strongly supports the view that blood is the essential food of hookworms, that they function as miniature leeches. But for the presence in them of a hæmolytic substance evidence is conflicting, and after their fresh experiments Fülleborn and Kikuth leave the matter open. But, as Huart notes, hæmolytic substances can be demonstrated in alcoholic and ethereal extracts of all normal organs. Furthermore, the Hamburg investigators fed mice with dozens of hookworms each, or injected them with their fresh or dried extracts to an extent which represented as many as 300 worms apiece, without producing the least anæmia. Acute hookworm anæmia is, then, essentially due to the grave intestinal hæmorrhage which accompanies it, yet in view of the damage produced in the kidney, it is rash to brush aside toxic action as a contributory cause.

As regards the more usual chronic anæmia, it is equally unreasonable to brush aside bleeding as a negligible factor in its causation. On the other hand, the toxic changes in the kidneys in acute canine cases are strongly reminiscent of those noted for man by B. K. Ashford and his colleagues in their report on the Porto Rico Anæmia Commission for 1905–06. Fresh evidence for the effects of this toxic renal damage seems to be offered by the observation of A. W. and J. N. Taves, quoted by A. A. Osman,[3] on the value of alkaline therapy in reducing the time needed to remove the gross lymph effusions of grave hookworm disease, so allowing this condition to be viewed alongside ordinary chronic parenchymatous nephritis. There is, then, abundant evidence of toxic damage in both acute and chronic hookworm infection, and its consequences should attract investigation; but there is no evidence that it is the important factor in causing hookworm anæmia, and in some circumstances there is clear evidence that it is not.

GEOGRAPHICAL INCIDENCE OF DIABETES.

Dr. C. A. Mills of Cincinnati has made a survey[4] of the incidence of diabetes mellitus in various countries. He finds it uncommon among the Chinese, in whom it is mild and accompanied by supersensitiveness to insulin. It is mild also, he says, in Japan and in India except among the wealthy leisured classes. It has been observed that the incidence is greater among Chinese who forsake their native diet for European foods, and among Irish inhabitants of Boston, emigrants from a country where the incidence is low. Dr. Mills thinks the incidence is largely affected by climatic conditions, and has collected figures which show that in the U.S.A. the diabetic death-rate is lowest in the southern States, while the western plateau and mountain States come next, followed by the northern States from Michigan west, the middle States from the Atlantic to the Pacific coasts, and finally the north-eastern States, with a rate 2·2 times as high as that of the southern group. That this cannot be explained on racial grounds has been shown by Lehman, who found that diabetes was as prevalent among negroes in the south

[3] THE LANCET, Nov. 1st, p. 945.
[4] Arch. Internal Med., Oct., 1930, p. 569.

as among white people. The further members of the negro race are taken from their natural tropical environment the higher becomes the death-rate from diabetes. In Canada the incidence seems to be considerably lower than in the United States, but there is the same variation in the diabetic death-rate from east to west as in the northern States. In Europe the distribution of the death-rate is peculiar; all the countries above the fiftieth parallel, with the exception of Ireland, have a diabetic death-rate above 9·6, while all below that parallel have a lower rate. Moreover, the rate is said to be increasing much more rapidly in the northern European countries than the southern. In Asia the rates were found to be considerably lower, where they could be obtained, being 3·19 in Japan, 2·7 in the Straits Settlement, and 6·5 in Ceylon; in South America the rate is everywhere low. In summarising his observations, Dr. Mills points out that the death-rate from diabetes seems to increase with the distance from the equator; the apparent exceptions of Japan and northern China he finds explicable on the grounds of their long tropical summers. He thinks it undoubtedly true that some races, notably the Chinese, are more prone to the disease if they forsake their native food for a foreign diet containing more sugar; but he considers the racial factor as a cause of varying incidence may be discarded, on the grounds of the difference in the diabetic death-rate between negroes in the northern and southern States, and between Irish in Boston and Ireland. In a further paper dealing with the relation of sugar consumption to the ætiology of diabetes mellitus, Dr. Mills recorded that he was unable to find any constant connexion between the two.

DENTAL CARIES AND DIET.

THE Committee for the Investigation of Dental Disease reports[1] an investigation by Mr. A. Deverall and Miss M. Reynolds into the influence of dietetic measures on the incidence and progress of caries in children's teeth. The investigation, which is under the supervision of Mrs. M. Mellanby and Dr. H. C. T. Langdon, has been in progress for nearly three years, and it is now possible to give some indication of the results which are being obtained. The total number of children under observation is approximately 860, housed in three similar institutions outside Birmingham. These were formerly under the poor-law authority, but are now under the local education authority. The ages of the children vary from 2 to 16 years. The basal diet is, on the whole, similar in all three institutions, and is one that would be generally regarded as thoroughly adequate. There is no significant difference in the character of the districts from which each institution draws its supply of children. The children have been grouped as follows for purposes of supplementary diet:—

(*a*) No addition to basal diet	20	children.
(*b*) Vitamins A and D (cod-liver oil and Radiostoleum)	225	,,
(*c*) Vitamin A (prepared from mammalian liver)	16	,,
(*d*) Vitamin D (Radiostol)	224	,,
(*e*) Olive oil	136	,,
(*f*) Treacle	261	,,

Every child is submitted to a detailed dental and physical examination at intervals of six months, the findings being carefully recorded. The data which have been accumulated up to the present time relate for the most part to children whose temporary teeth, with many of the permanent teeth, had already erupted at the beginning of the investigation, an average of about 19 per cent. of the teeth being already carious. This proportion was similar in all groups. The figures relate therefore to the influence of diet on the progress of caries in teeth which are already formed, and not to the effect on teeth in course of development. It was found, after four inspections representing one and a half years, that the percentage of teeth developing caries during this period in groups (*b*) and (*d*) was approximately half that in the control groups.

BRONCHIAL OBSTRUCTION.

WRITING on the mechanism of physical signs, Dr. Chevalier Jackson[1] discusses the signs produced by partial or complete bronchial obstruction by foreign body or neoplasm, and recognises three types of bronchial obstruction as follows: (1) The stop-valve obstruction, in which the bronchus is completely blocked so that no air can get either in or out, with the result that the residual air is absorbed and collapse of the affected portion of the lung follows with the usual signs of dullness, absent breath sounds, and displacement of the mediastinum to the affected side. (2) The check-valve obstruction can be demonstrated by bronchoscopy and may prevent the flow of air from entering the lung, but allow it to re-escape, thus producing atelectasis, or by acting in the opposite direction air can enter but not leave the lung, so that an area of emphysema is produced. Sometimes when a tumour is situated near the bifurcation of a bronchus it will block one branch during inspiration and the other during expiration so that the part of the lung supplied by the bronchus which is blocked only during inspiration will collapse, but the portion of lung supplied by the bronchus which is blocked only during expiration will become emphysematous. (3) The by-pass valve obstruction. Here the bronchus is only narrowed so that some air can enter and leave. An asthmatoid wheeze is heard at the open mouth of the patient in many cases though not audible at the chest wall.

One type of obstruction may alternate with or follow another and this can be seen by bronchoscopy. The importance of this method of examination and of treatment through a bronchoscope is becoming more recognised and the paper will be useful to those interested in this branch of medicine.

BOVINE TUBERCLE BACILLI IN HUMAN PHTHISIS.

SINCE the two types of human bacilli have been clearly differentiated, almost all investigations have gone to show that ordinary adult phthisis is caused by the human bacillus and that for practical purposes the bovine bacillus may be ignored. In the current number of the *Journal of Pathology and Bacteriology* (vol. xxxiii., p. 1145) Dr. A. Stanley Griffith has collected together the available information which puts rather a different light on the question. In 926 examintations made in foreign countries all yielded human bacilli, which in three instances were mixed with bovine bacilli. The English investigations, mostly made by Dr. Griffith and his colleagues showed three examples of bovine bacilli in 327 sputa tested. On the other hand, in recent years, Dr. W. T. Munro, of the Glenlomond Sanatorium, an

others in Scotland, have found quite a surprising number of bovine infections.[1] Of 468 cases, 450 yielded human bacilli, 17 bovine bacilli, and 1 both. In a number of cases the bacilli were isolated from the sputum and tested on more than one occasion; a number were also tested by Prof. W. J. Tulloch. In two fatal cases autopsies were obtained and bovine bacilli were obtained from the lungs. There can, therefore, be no doubt that a fair proportion of cases of ordinary adult phthisis in Scotland are due to the bovine bacillus. The mode of infection is more difficult to be sure of. No evidence was obtained that any of the patients had acquired infection from a previous case. The clinical histories indicated rather a primary alimentary infection though, as Dr. Griffith points out, bovine bacilli are known in children to infect occasionally through the respiratory passages. If bovine infection accounts for 4 per cent. of cases of phthisis in Scotland, it is easier to understand how they may get into a fresh person by inhalation. The disease produced is not clinically differentiated from that caused by the human bacillus. Previous work has shown, though not very clearly, that bovine bacilli are relatively more important in other forms of tuberculosis in Scotland than in England; these new figures provide further reason for looking to the dairying industry.

READING IN HOSPITAL.

FROM the needs of wounded and interned soldiers during the war arose a keen realisation of the importance of books to the sick and unoccupied. The Red Cross War Library grew out of the work of Mrs. Gaskell and Mr. Hagberg Wright, and after the Armistice the joint council of the Order of St. John and the Red Cross granted a capital sum for the supply of books in hospitals, primarily to ex-Service men. The work has steadily extended to the civil population, and now over 2000 hospitals are supplied. Thanks to public gifts in money and kind, to the voluntary work of collectors throughout the country, and to volunteer workers in the wards and at the Central Library at Lancaster Gate, this service has hitherto been provided without any charge to the hospitals, but the time has now come when the organisers are obliged to make an appeal for assistance. We reported not long ago[2] a conference at Cambridge of members of the Library Association; the subject was discussed again at a meeting in connexion with the Public Health Congress last week. Dr. H. L. Eason urged the great importance of the personal distribution of books by a skilled librarian or voluntary worker, preferably somebody outside the ordinary routine of the hospital. Patients, he said, would not be allowed to help themselves indiscriminately from their medicine bottles, and the books should be given out to them by somebody who knew both book and patient. The President of the College of Nursing assured the meeting that if nurses had been an obstacle in the past they were so no longer, and the hospital librarian would receive a cordial welcome everywhere. Mr. C. E. A. Bedwell, house governor of King's College Hospital, suggested that if the nurses were now educated it was time to go on to the education of the chaplains, in whose hands the distribution of literature so often lay. Still more important, and certainly more delicate, is the provision of books for patients in mental hospitals, who have to spend many months in the limited social environment of their ward. Their case was eloquently put by Mr. L. G. Brock, chairman of the Board of Control, Dr. Doris Odlum, and Miss E. L. Macaulay, all of whom emphasised the great therapeutic value of reading and the necessity for a supply of clean and up-to-date books, distributed by a librarian with some psychological training. Fashions in thrillers and love stories change almost as quickly as fashions in hats, and patients will not read the popular books of the generation before last. Dr. Odlum pointed out that many of the patients in these institutions would be subscribers to public libraries if they were at home, and she suggested that some arrangement should be made with the librarians for the supply of books to them in hospital. She agreed with Dr. Eason that it was important for the books to be taken to the patient and not to be available only for those who were well enough to go to the library, and pointed out the value of persuading a patient to start reading —if only a paragraph a day—in bringing him or her back to social life. The proper use of books as a branch of therapy has been neglected too long; the hospitals are now alive to the need, but, as Dr. Eason confessed, it is largely a question of money.

[1] Five were reported by Dr. Munro, in THE LANCET, 1928, i., 384.

[2] THE LANCET, Oct. 4th, p. 777.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS.

THIS society has met twice in the course of the year. During the month of June, under the presidency of Sir Percy Sargent, a study was made of neurological surgery in Paris. Visits were paid to the clinic of Dr. André Thomas, who showed cases of surgical interest, including a demonstration of the pilo-motor reflexes, to our knowledge of which he has contributed so greatly. At the Salpêtrière cases were shown by Prof. Alajouanin. Mr. de Martel performed several neurological operations, and Dr. Clovis Vincent did a laminectomy for an intramedullary tumour of the cord. At the November meeting just held in London Mr. Bathe Rawling and Mr. C. P. G. Wakeley performed operations at the West End Hospital for Nervous Diseases, Regent's Park, while Dr. Worster-Drought and Dr. Carnegie Dickson demonstrated cases and pathological specimens and the like. Mr. Lambert Rogers made a communication on the nature of the foramen of Magendie. The annual dinner was held at the Langham Hotel in the evening.

HOSPITAL FOR TROPICAL DISEASES.

WITH the opening of new wards and of a clinical lecture theatre at the Hospital for Tropical Diseases in Endsleigh-gardens, another landmark has been reached in the history of that remarkable venture. Mr. William Lunn, Under-Secretary for Dominion Affairs, who formally opened the additions on Thursday of last week, said quite truly that, with one possible exception, no other branch of medicine has grown and developed in so short a space of time. It was only in the last year of the nineteenth century that, under the inspiration of Patrick Manson, the governors of the Albert Dock Hospital consented to the attachment of a school of tropical medicine. Growth was so vigorous that on coming of age the combined school and hospital was well able to occupy the magnificent building in Endsleigh-gardens, designed by Mr. Stanley Hamp, which was in the gift of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society. And five years ago, when the school was transferred to Keppel-street to become a part of the London School of Hygiene

and Tropical Medicine, the nominal divorce was no catastrophe to the hospital, which obtained the space it then needed for expansion and improvement, while it retained the coöperation in daily work along with a free exchange of facilities with the other. Before the formal opening Sir Walter Fletcher delivered an address on the work of the hospital and on its value as a centre for clinical teaching and research in tropical medicine. He commented on the threefold work of the hospital. Its patients are drawn from the contacts of our seafaring trade, from the coasts of India, Ceylon, and Burma, from the Gold Coast, and from the Malay States. All classes are helped without regard to colour, to creed, or to social rank. They include officers and men of the mercantile marine, planters, engineers, missionaries, traders, the explorers who develop the Empire, and the servants of the State who administer it in all its various and distant parts. Its second great function was the development of Manson's idea to found a school for affording instruction in tropical medicine to medical officers in the colonial service, and the lecture theatre was to perpetuate Manson's name. The hospital had further inestimable value in the training of nurses to meet the special problems of disease in tropical climates. Finally, it was a centre of research inseparable from the daily work of the healer or teacher, and the only source of progress in the cure and prevention of disease. Manson had himself taught the lesson that the clinician dealing with disease must acquire his own skill in the technical methods of the laboratory. But in spite of the work of Manson and of Ross malaria had not yet been conquered. There were to-day more, not fewer, sufferers from malaria in India, and even in the tercentenary year of the introduction of Jesuits' bark, physicians were, Sir Walter said, still ignorant which constituent of the bark was the most effective against malaria. He wished the hospital well, not only for the sake of sufferers from disease, but for the sake of the better development and greater happiness of every part of the Empire. The new wards, pathological laboratories, and demonstration theatre have been added at a cost of £13,000, raised by the efforts of Sir Leslie Wilson.

ERNST FUCHS.

THE death last Sunday in Vienna of Hofrat Prof. Ernst Fuchs in his eightieth year removes one who had come to be known as "the grand old man" of ophthalmology. Few can have had a wider circle of friends and acquaintances, and many, in countries as far apart as Austria and China, India and America, will feel sad that they will see him no more. His dinner parties at his delightful home in Vienna in pre-war days were usually of the nature of an international gathering. Fuchs was an excellent linguist and an ideal host. A great traveller, there can be few countries of any note he had not visited. He was a very hard worker and a prolific writer. His Text-book of Ophthalmology, one of the best medical text-books ever written, has run through some dozen German editions, half a dozen English ones, and has been translated into many other languages. Fuchs, like many great men, was a very humble one. He would ask anyone working in his clinic who possessed special knowledge to impart it to him. He would discuss sympathetically any difficulty or problem with those far inferior to himself in knowledge and give of his best to them. Few, if any students, left his clinic without a feeling of regret and a real affection for the man himself. Fuchs was formerly a wealthy man but the war left him impoverished. How he faced that difficulty at an advanced age, and overcame it by working abroad, is a testimony both to his personal courage and to the esteem in which he was held outside Austria. In this country his name will be put in the niche of fame alongside those of Bowman, Donders, von Graefe, and Nettleship.

GRÜNFELDER'S TOE REFLEX.

Dr. Hildegard Rothe [1] has published the results of investigations made at the Berlin Children's Hospital into the reflex recently described by Grünfelder. This reflex, which is of interest to otologists and to pædiatrists, consists in dorsal flexion of the great toe combined with a fan-wise spreading of the other toes. As described by Grünfelder,[2] it is elicited by continued pressure on an area of the skull at the intersection of the lambdoid, occipito-mastoid, and parietomastoid sutures, which corresponds in the infant with a corner of the posterior lateral fontanelle; and it is found in the presence of disease of the middle ear in children up to the age of five years. It is especially in infants and young children that inflammation of the middle ear is difficult to determine and apt to escape recognition, and here Grünfelder's reflex may be useful if it proves reliable. Dr. Rothe has looked for it in about 150 children with disease of the ear, and in the same number of children with healthy ears. She finds that it is usually spontaneous, but that it is increased, and sometimes elicited when otherwise absent, by pressure on the region mentioned by Grünfelder; it does not always take the form originally described, but sometimes consists in dorsal flexion of the great toe with plantar flexion of the other toes, and sometimes in a fan-wise spreading of the little toes without marked dorsal flexion of the great toe; it is therefore not always equally easy to recognise. The reflex is crossed—that is, it is seen in the left foot in disease of the right ear, and vice versa. Dr. Rothe confirms Dr. Grünfelder's statement that it is found early in otitis media before visible changes in the drum membrane, and she associates it with increase of pressure in the tympanum. She found it present 98 times in 100 cases of acute otitis media before perforation, 12 times in 47 cases of suppurative otitis after perforation, and 3 times in 15 cases of mastoiditis with discharge; but not at all in 4 cases of Eustachian catarrh, and only 3 times in 150 cases of other illnesses without disease of the ear. When the reflex occurred after perforation of the drum there was usually insufficient drainage, with pulsation of discharge, redness, or swelling of the drum. In one case antrotomy was followed by fall of temperature and disappearance of the reflex. Of the three children with other diseases who showed the reflex, one was suffering from encephalitis, one had external otitis and one had rhinopharyngitis without showing any sign of aural disease on repeated examination. These findings suggest that the reflex is indeed a reliable indication of disease of the tympanum in young children.

Dr. C. S. Myers, who has been director of the National Institute of Industrial Psychology since its inception, has been appointed principal of the institute in order that he may devote the whole of his time to research and educational activities. Mr. G. H. Miles, D.Sc., who has been assistant director for several years, has been appointed director and will take charge of the whole of its practical activities.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCXIII.—AFTER-TREATMENT OF SOME COMMON OPERATIONS.

PART II.*

OPERATIONS FOR SUPPURATIVE CONDITIONS.

AFTER operations for suppurative appendicitis, and those on the colon, 25 c.cm. of anti-gas-gangrene (*B. welchii*) serum should be given subcutaneously and may be repeated every three days in 10 c.cm. doses in bad cases. In adults, it is unnecessary to drain the peritoneum in most cases of gangrenous appendicitis, provided that the appendix in perforating has not discharged its contents into the peritoneum; a strip of corrugated rubber is inserted through the abdominal wall, going only down to the outer aspect of the peritoneum. This should not be removed before the fifth day. In children it is wiser to drain the peritoneal cavity in every case where a gangrenous appendix is found.

In suppurative peritonitis a tube is inserted into the pelvis large enough to allow of its lumen being cleaned and dried out each day with a long probe and dry ribbon gauze. This tube is turned daily and is kept in position until the purulent discharge ceases; there seems to be no advantage in removing the tube early, for this causes the abdominal wall muscles to close the track, and a residual abscess may result. When the tube is removed the track should be left open and not plugged with the so-called wick of gauze. I always fix an abdominal tube to the skin with a loop of silkworm gut which can be slipped over the end of the tube to allow it to be turned, after which the loop is replaced. If an abdominal tube should slip out prematurely, a not uncommon accident, no attempt should be made to push it back, for it is nearly always impossible to replace it in its original track; immediately after the tube has come out an adjacent coil of ileum takes its place. If the tube is then reinserted it passes into the pelvis on the wrong side of this coil, kinks it, and causes it to adhere to the old track of the tube. In this way the dangerous complication of acute obstruction of the small intestine is produced. If, then, such a tube comes out and needs replacement, an anæsthetic must be given, the wound must be reopened sufficiently for the introduction of one's finger into the pelvis, and a tube is replaced in its original relationship to the dangerous coil of intestine.

Acute mechanical obstruction of the small intestine is, perhaps, the most serious complication of pelvic peritonitis; it can usually be prevented by delivering, during the operation, the last coil of ileum from the pelvis and carefully peeling from it, and from the under side of its mesentery, every trace of lymph. Acute obstruction of this type occurs, as a rule, after the first week; its onset is sudden, and is indicated by two symptoms—colicky pain and vomiting—and it leads to very rapid exhaustion. The vomiting may not be present if the patient is being starved. Immediate operation is necessary, by reopening and perhaps enlarging the wound; the adherent coil of ileum is then delivered and examined, and it is usually not necessary to do more than remove the adhesions which are causing the kinks. Sometimes, however, so long a piece of intestine is involved in complicated bends and twists that it is better and quicker to do a rapid entero-enterostomy than to attempt to unravel it. In cases that have been allowed to go on to fæcal vomiting and severe distension, an enterostomy should be performed by inserting a small flanged tube into the coil above the obstruction; it is a simple matter to make the opening watertight by infolding sutures, and the coil may be replaced into the abdomen with safety, so that the subsequent fistula may close itself within a week or two.

A less common variety of obstruction is due to the parietal peritoneum not having been sewn up sufficiently closely round a drainage-tube, so that a knuckle of intestine escapes to lie either under the muscles or under the skin, and it becomes strangulated. Early operation, possibly involving resection of the coil, is necessary for this complication.

Drainage-tubes inserted into the pelvis should have very small lateral holes, because it is not uncommon for a fringe of omentum, an appendix epiploica, or the fimbriated end of a Fallopian tube to strangulate through holes of large enough size. Such an occurrence is revealed when the removal of the tube is attempted, and it calls for ligature and division of the adherent structure.

Spontaneous fæcal fistula occurs from time to time after operations for acute appendicitis, usually after the fourth day. The drainage-tube should be withdrawn and the patient placed in the supine position; this allows the track to become angulated and encourages its closure. Such fæcal fistulæ usually close spontaneously within a fortnight if the colon is regularly cleared of its contents, but occasionally an operation has to be performed to close the fistula.

Two varieties of *secondary hæmorrhage* may occur after an operation for appendicitis performed through a para-rectus incision; in one type there is external bleeding, in the other the hæmorrhage is into the colon and is evacuated from the rectum. The former variety usually results from erosion of the deep epigastric vessels or their tributaries, and calls for immediate exploration of the wound and ligature of the vessel above and below the bleeding-point. The internal type of hæmorrhage is due to ulceration of the cæcum at the site of the base of the appendix; the abdomen should be opened, the cæcum freed and delivered, and the ulcerated and bleeding area should be infolded by deep sutures.

Residual abscesses are usually the result of removing drainage-tubes too soon; they are particularly liable to occur in children, and are most commonly placed in the recto-vesical pouch. It is true that such an abscess can sometimes be left to develop until the appearance of mucus in the rectum shows that the abscess is adherent to the rectal wall, through which it is then opened, but I believe that it is better not to wait for this stage but to drain the abscess from above as soon as it is diagnosed; its signs will be the recurrence of fever and the palpation of a mass on rectal examination.

A fairly common position for residual abscess, again in children, is above and in front of the bladder; here it is easily palpable, but the swelling is apt to be overlooked, owing to its close proximity to the pubes. Abscesses in this position are adherent to the abdominal wall, and should be drained through a fresh incision without reopening the general peritoneal cavity.

Senior Surgeon to Out-patients, St. Mary's Hospital; Surgeon, Paddington Green Children's Hospital.

* Part I. appeared last week.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL.

PRESIDENT'S ADDRESS.

AT the opening of the 132nd session of the Council on Nov. 25th, Sir Donald MacAlister, the President, alluded to the death of Sir Francis Champneys, a former member of the Council, who held a unique place in the important branch of practice to which he had devoted himself, and whose counsel was sought and valued since his retirement; to the appointment by the University of St. Andrews of Prof. David Waterston as its representative; and to the knighthood conferred on Sir Norman Bennett, a former Crown member of the Council.

INDIAN MEDICAL DEGREES.

"The India Office," said Sir Donald, "has communicated to us the report of a conference of provincial and university representatives, held at Simla during the summer, for the purpose of considering the creation of an All-India Medical Council. After a full and frank discussion of the position, it was agreed that the creation of such an All-India organisation, for the purpose of maintaining a uniform standard of qualifications for the graduates of Indian universities, is essential and acceptable in principle. Resolutions concerning the constitution and functions of the proposed Council were adopted, and commended to the Indian Government as the basis of central legislation; and it was urged that without undue delay the necessary steps be taken to bring the new law into operation. The Council cannot but express its satisfaction that a solution of the vexed question of Indian medical standards, applicable to the whole of British India, should be practically envisaged by the Government of India; and that the responsibility for maintaining these standards, especially in relation to their extra-Indian aspects, should be assumed by a central Indian body having statutory authority. The application of Part II. of the Medical Act, 1886, was made in 1892 by Her Majesty in Council to India as a whole, without reference to its Provinces. The Council has accordingly, throughout its discussions on the subject of Indian medical qualifications, continued to look to the Central Government for the information and the guarantees without which its functions under the Act cannot be properly performed. It therefore counts with confidence on the speedy establishment of a Central Board or Council for India, comparable with the Medical Boards or Councils of other parts of the Empire with which this Council is in regular official communication, and to which it can refer for authoritative information on all questions of local professional qualifications and standards.

"Communications have been received from India suggesting, that pending the establishment of the All-India Council, special and exceptional measures should be taken by us for the recognition of medical degrees granted by the Universities of Bombay and Rangoon. The Executive Committee have given careful consideration to these applications, but have come to the conclusion that it would not be expedient or indeed just to accede to them until the question can be dealt with as a whole, under conditions which would justify the Council's guarantee of their sufficiency."

AUSTRALIA AND CANADA.

"As regards the Commonwealth of Australia and the Dominion of Canada, the position at the present time happens, for historic reasons, to present a different aspect. The several States of Australia, and the several Provinces of Canada, may by Order in Council enter into relations of reciprocity with this country separately. But no such Order in Council has been made applying the Medical Act, 1886, to the Commonwealth as a whole, or to the Dominion as a whole. If at any time Australia or Canada should choose to establish a Central Board and a single standard of qualification, reciprocally recognised by the several States or Provinces, and valid over the whole territory, it would remove certain disabilities and difficulties encountered now by their own medical graduates, and simplify the procedure of recognition and registration in this country. It would then rest with His Majesty in Council, if so advised, to apply Part II. of the Medical Act, 1886, to the Commonwealth or to the Dominion, as it is now applied to British India. As the method and the results of establishing reciprocity between the parts of the Empire are somewhat complex, and owing to circumstances diverse in different cases, I have, at the request of the Privy Council, had a memorandum drawn up by the Registrar, setting forth the particulars of the existing law. This has been received by the Executive Committee and approved for circulation."

FRANCE.

Further correspondence had taken place with the French Government on the question of permits to British practitioners to practise in hospitals established in France for British patients. "The French law," said the President, "appears to be definite, that such British practitioners must possess French qualifications; but negotiations are still going on, and the question is not yet closed. As I pointed out in May, the British law expressly permits French practitioners, not registered in this country, to act as medical officers in hospitals established here for 'the relief of foreigners in sickness.' What is desired is that, if practicable, some corresponding concession should be authorised in France."

Committee Work.

The interim report from the Departmental Committee on Maternal Mortality and Morbidity had been referred to the joint committee of the Education and Examination Committees which already had under consideration the report of the Medical Officers of Health Committee on education and examination in preventive medicine. Inspectors and Visitors of Final and Qualifying Examinations had been active during the recess in attending on the several licensing bodies, and an interim report on certain features of the examinations might be presented. The Public Health Committee was to report on certain proposed changes in the rules now in force for diplomas in public health. The Pharmacopœia Committee would present a report setting forth the progress made in drafting the text of the next British Pharmacopœia. It now appeared impracticable to complete the text by the end of the year as had been hoped. Meanwhile the Committee had authorised the issue of a first report of the Pharmacy Subcommittee, giving a list of proposed changes in the method of preparation of

certain pharmacopœial articles. Effective coöperation with the revision committee of the United States Pharmacopœia Convention had been assured. The problem of attestation and evaluation of certificates of attainments, &c., presented by students from overseas, applying for admission to medical schools and universities in this country, had been the subject of inquiry and discussion by the Special Committee appointed for this purpose. Valuable progress had been made, and negotiations opened up with authoritative bodies abroad, more particularly in the United States. These promised to put the question on a satisfactory footing, and to meet the convenience of medical schools and examining bodies in both countries.

At the conclusion of his address a vote of thanks to the President was proposed by Sir Leslie Mackenzie and seconded by Sir Norman Walker. The Council then passed to the consideration of disciplinary cases.

PAINTING AND THE HEALING ART.

LLOYD ROBERTS LECTURE.

Prof. William Rothenstein, Principal of the Royal College of Art, South Kensington, delivered the eighth Lloyd Roberts Lecture before the Medical Society of London on Nov. 19th, the President of the Society, Dr. R. A. Young, being in the chair.

Prof. Rothenstein, who took for his subject Painting and the Healing Art, said that nothing seemed to him more absurd than the distinction which was made between material science and idealistic art, which were both devoted to the pursuit of truth for its own sake. Neither art nor medicine could be called exact studies, but science, art, religion, and, indeed, philosophy, which all dealt with the real things of life, invited the most frequent charlatanism. There seemed little doubt, however, that in mediæval times artists were the precise thinkers, and he found it constantly difficult to believe, when he realised the extreme intellectual power of the mediæval artists, that they had in them even the elements of charlatanism. It was the more difficult from the point of view of art, when looking at the mediæval period, to believe that scientific men, particularly doctors, could have been associated with the tenets of astrology to the extent that the historian would have us believe. The historian of to-day might blunder similarly. Anyone looking at the mass of literature exposed on the railway bookstalls would find it difficult to believe that we had real writers and real thinkers.

THE ARTIST AS HUMANIST.

In the same way, he continued, in mediæval times the more serious side of life, as represented by the sciences—for example, medicine—was only familiar to the few, while the manifestations of quackery were obvious to the many. The humanistic side of life had always had its appeal among creative people, and this was as strong in the past as it is to-day, and came out in works of art produced under high patronage. Church and State used the artist's powers for purposes of advertising. Kings commissioned him to show the terrible things that would happen if anybody went against them, as the Assyrian and other sculptures in the British Museum show. In the same way the Church used the artist to show what would happen to disobedient people, the awful tortures that would be inflicted on those who did not obey the Church, and the blissful future of those who did. It seems very unlikely that physicians, physicists, and men of science of every kind were really devoted to alchemy and astrology to the extent illustrations in mediæval books lead us to believe; and popular histories may be misleading.

After reference to the knowledge of medicine and surgery possessed, from the earliest days, by Eastern peoples, the lecturer went on to show that mediæval pictures, painted by artists at the behests of the Church, showed profound sympathy for human suffering by depicting the actions of the saints in performing so many of their miracles. The number of pictures of saints performing miracles to remove or relieve sickness was, he believed, larger than the number of pictures devoted to other subjects. The artists believed in the truth of the underlying motif of these pictures, and pursued it for use in the service of any master. A student of early painting showed that there were more paintings illustrating the lives of the saints, subjects which allowed of an enlightened humanism, than motives from the Old or the New Testament. In the days of the Middle Ages, when terrible wars were devastating Europe, artists used all the latitude allowed them by the Church to inculcate pity for the suffering in the depicting of miracles, and the portrayal of these scenes included dignified and noble figures who often represented the scientific men of the period. Prof. Rothenstein could not believe that the dignity of these personages could be associated with humbug and charlatanism. The best way to understand the past was to understand the present. There were in mediæval times movements going through the world that those engaged in art and those engaged in healing were alike subject to. A desire to alleviate the general misery and a feeling for the beauty that was in the world—when the world was a much more cruel place than now—was shared alike by men of science, artists, and writers, while the emotional truth of a subject might be greater at times than the precise truth.

ART, SCIENCE, AND TRUTH.

During the Renaissance when medical science was beginning to assert itself, when the scientific spirit was ready to express itself freely, artists became interested in the more scientific aspects of art—namely, in perspective and anatomy. He doubted if the new Greek learning, coming suddenly into Italy, threw so great a light upon the directions of human endeavour as historians thought. The Greek learning allowed men who had suspected certain scientific truths to express them without being burned alive, and art enjoyed similar freedom. With reference to the study of anatomy, anatomical knowledge was not so necessary as many surgeons believe, because appearance may express what lies behind appearance. Ruskin preached the value of geological knowledge, but the artist worked with the eye, and a fine eye would see and express much that it did not understand from the scientific angle. Both the artist and the scientific man had intuitions. Both Newton and Einstein might conceive their intuitions of truth in a flash; they must spend months or years in proving their intuitions to be true: the artist had this advantage, he could express his at once. The medical man of any period, with a fine knowledge of the human heart, and through the practice of profound observation of what happens in life, was probably as good a medical man as many physicians of to-day, though without their equipment. It is profound knowledge of what happens every day

in this life which enables a man best to deal with its manifestations, and it was possible that a medical man of to-day with high scientific attainments might be following principles and formulas to no purpose, whereas another man with finer intuition, though less book knowledge, might in the end be of more service to mankind. The artist and the healer were actually at one; they were not pursuing different purposes; their common search was for truth, and both depended on intuitive faculties.

SOME APT ILLUSTRATIONS.

Prof. Rothenstein emphasised the points of his lecture by showing on the screen lantern slides of a number of paintings, and of the famous piece of sculpture, the "Dying Gladiator," all illustrating the devotion of the artist to the humanistic side of life. He pointed out that to make the enemy as noble as the friend was a sentiment which goes right through Italian painting, the dignity of humanity having first place.

The following are the subjects thrown on the screen with the names of the artists, and Prof. Rothenstein made running remarks while they were being shown. Fra Angelico and Domenichino, "The Distribution of Alms," the picture by Fra Angelico being the famous one of St. Nicholas. Carpaccio, "The Birth of the Virgin," when the lecturer pointed out that the feelings of order and tranquillity, of harmony and repose, showed a fine sense of contemporary medical care. In a drawing and a painting by Signorelli, he called attention to the extraordinarily living and vivid expression of the nude, and to the display of scientific understanding in the foreshortening. To the picture by Bellini "Circumcision by Rabbis," in the National Gallery, he drew attention as a fine, and even noble, representation of the operation, while of the picture by Lorenzo Lotto, "Portrait of a Doctor," it was difficult, he said, to believe that a man of such grave and splendid appearance could have been anything but a truthful scholar. Another picture by Domenichino, "A Saint Performing a Miracle," led to the comment that the artists in scenes of this kind probably painted their scientific friends; while of a picture by Ghirlandajo, depicting a man suffering from rhinophyma, he said it was difficult to imagine a modern person with courage to sit for such a picture. In a picture by Breughel, "the Blind leading the Blind," he said that the accuracy of representation was beyond praise; while he commended the realism and serious character of three pictures by Rembrandt, "Christ at a Sick Bedside," the "Lecture on Anatomy," and the fragment of a "Lesson of Anatomy." Of two famous pictures by Rubens, "The Descent from the Cross," and a portrait of his wife, the lecturer spoke with admiration. He pointed out that in the first the artist had been able to show wonderfully by depicting the loss of vitality the difference between the dead figure and the living figures. Of the portrait he said that the large eyes and prominent neck had been criticised as symptoms of the well-known association of goitre and a disease of the eyes, but he did not find such criticism sound. He held that the full neck and large eyes were used to exaggerate the subject's beauty; art and science parted company here, and to criticise a slight exaggeration of human loveliness is using the scalpel too early. Of one of the many pictures by Velasquez representing dwarfs, he said that the method of presentation was humanistic, no spirit of ridicule entering in.

Prof. Rothenstein's address was followed closely by a large and appreciative audience.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE annual meeting of Fellows and Members was held in the theatre of the College on Nov. 20th, Lord Moynihan, the President, being in the chair. Five members of the Council, two other Fellows, and fifty Members attended the meeting.

THE ANNUAL REPORT.

The President referred to the decision to hold a Primary Fellowship examination in Australia next year; the first awards of the Diploma in Gynæcology and Obstetrics, the Macloghlin scholarships, and the Mackenzie Mackinnon research fellowships; the award of the honorary gold medal of the College to Prof. G. Elliot Smith and Mr. R. Lawford Knaggs; and generous grants which had been made by Lord Melchett, Sir Louis Baron, and Lord Beaverbrook for the endowment of research scholarships in the College.

Dr. Richard Gillbard asked what were the receipts during the past year from the granting of Fellowship and Membership diplomas, what were the figures for the attendance of members of the Council at meetings, and whether it was possible for men to become Fellows without having previously passed the Membership examinations. Dr. David Roxburgh asked the reasons for holding a Primary Fellowship examination in Canada, suggesting that such examinations would lower the standard of the Fellowship.

The President replied that the net receipts from the granting of diplomas in the past year had been £5692 on Membership diplomas and £2326 on Fellowship diplomas; he commented on the diligent attendance of members of the Council as shown by the figures given in the report. The question of examinations in Canada had been dealt with fully at the annual meeting last year; it was one to which the Council had given the most careful attention, and there was a consensus of opinion that these examinations were to the advantage both of the College and of surgery.

DIRECT REPRESENTATION OF MEMBERS.

Mr. Ernest E. Ware then moved:

That this forty-second annual meeting of Fellows and Members of the Royal College of Surgeons again affirms the desirability of admitting Members, who constitute nine-tenths of the College roll, to direct representation on the Council of the College. That the result of the recent poll of Members resident in the United Kingdom and the Irish Free State (taken by the Society of Members in response to reply of the Council, Dec. 12th, 1929), which is as follows:

Cards sent out	12,766	Against representation	156
Cards returned	166	Majority in favour ..	6676
Cards not valid	58	By personal canvas in favour	106
In favour of representation	6832		

provides indisputable evidence that this change in the constitution of the College is desired by a very considerable number of the Members of the College.

Mr. Ware emphasised the justice of his appeal, which accounted for the persistence with which similar resolutions had been moved for over 40 years, and commented on the absence of rancour at recent annual meetings. Direct representation of Members would strengthen the position of the Council of the College. The statements made by the President at the last annual meeting and by the Council in their reply to the resolution then passed had been taken

as evidence that the Council viewed this question with an open mind; thus encouraged, the Society of Members had taken a poll of the majority of Members of the College; lack of funds had rendered a poll of the complete body of Members impossible. He remarked on the convincing majority shown by the figures embodied in the motion, and stated that it was desired that a certain number of Members should be elected by Members to sit on the Council of the College.

Dr. Windham L. Gillbard, seconding the motion, referred to the fact that 55 per cent. of the Members to whom cards had been sent had replied, and that, of those who had replied, 96 per cent. were in favour of the direct representation of Members. Dr. Arthur Haydon, speaking in favour of the resolution, advocated a geographical representation of Members on the Council. The College, he said, ought to be in a position to defend its Members against competition from unqualified practitioners. Dr. F. W. Collingwood said that men who were doing such important work as the Members ought to have a better status in the College. Dr. T. Wilson Parry, admitting that from a legal point of view Members had no case, appealed to the ethical justice of the College. Other speakers in support of the resolution were Dr. Howard Stratford, Dr. Richard Gillbard, and Dr. Edwin D. Kite.

The President said the question of direct representation of Members had always been regarded by the Council as a matter of the gravest importance, and had always been debated without ill-feeling. The Council this year had decided to meet in committee to consider the resolution passed at this meeting, the proceedings of which would be duly reported to them.

The question was then put and carried by 43 votes to 1.

ROYAL SOCIETY OF MEDICINE.

ANNUAL DINNER.

THE annual dinner of this Society took place on Thursday, Nov. 20th, at the May Fair Hotel, the chair being occupied by Dr. T. Watts Eden, President of the Society. H.R.H. the Duke of York was the guest of honour and the Bishop of Birmingham (Right Rev. W. E. Barnes) was also a specially invited guest. There was a large and distinguished attendance. The toast of "The King" having been duly pledged, the Duke of York proposed "The Royal Society of Medicine."

His Royal Highness referred to the great history of the Society, with that of its precursor, the Royal Medico-Chirurgical. In the rush of everyday work it was good for Fellows to meet annually in this way to renew their good fellowship, and in a tavern, where many great movements had originated. He diagnosed, especially in view of its undoubted appetite, that the health of the Society was good, so that it might be good advice to take "cures" at a tavern instead of going to Bath and Harrogate. He especially admired the aim of the Council to stimulate and encourage its Fellows in their labours, however scattered they might be in the outposts of Empire. There was every reason to be proud of the wonderful library, and of the new method of sending to remote places photographs of important scientific documents and treatises. The "Proceedings" must also be a most valuable publication, especially to those unable to attend the meetings. Realising that this great Society had been built up by the enthusiasm and devotion of members of the profession, the better to equip themselves for their warfare against pain and disease, he felt honoured that he had been asked to propose the toast.

The President, in responding, said that a new conception was growing up in the public mind concerning the primary function of the doctor—namely, that it was to keep the citizen in good health, that of attending to his ailments being secondary. Such a conception had been powerfully stimulated by the series of informative reports which had been issued by the Ministry of Health in recent years. Some time must be allowed, however, to give opportunity to the profession to adjust itself to this new conception. One of the most important tasks of the sections of the Society was to examine new methods and scrutinise the data on which such methods rested, so as to assess their value for practical application. The acknowledged differences of medical opinion met with was a constant topic of comment by the public, some of whom regarded it as a weak spot in the profession, but the speaker thought it fairer to regard it as an evolutionary phenomenon, leading, all hoped, to eventual progress. And the medical was not the only profession in which lack of uniformity of opinion was marked; witness the theological. Dr. Watts Eden referred briefly to the increasing complexity of the terminology in which the discussions at the different sections were now carried on. The need for a clearing-house of medical opinion was greater now than ever before; research was in the air, and the demand for it was great, but the profession never forgot that it exists to render practical service to the community. The Society had means, collectively, of examining the whole of the field, much of which was always new, and of arranging the patchwork results of research into useful patterns.

The toast of "The Guests" was proposed by Dr. F. M. R. Walshe, who, after expressing the special gratification of the Society in the presence of His Royal Highness, said that he would depart from custom in the toast that had been confided to him, knowing how deep-seated in the Anglo-Saxon temperament is the abhorrence of public eulogy, so that when the public orator at an ancient University introduces the recipients of honorary degrees, he does so in a Latin speech, public praise being tolerable to its subject only when spoken in a tongue that no one present can understand.

"I am resolved," he continued, "that our guests shall not suffer embarrassment at my hands, and I feel that I shall best consult their pleasure by explaining their hosts to them. This is not the bizarre suggestion it may appear. For if that grotesque figment, the doctor of the novelist, the playwright and the journalist truly embodies the public conception of us, we are sadly misunderstood. A number of unexpected components go to make up the doctor of modern fiction. First and foremost he must be a surgeon; a surgeon of incomparable skill and strong sex appeal. He lets blood copiously with long sensitive fingers and the calm of the strong silent man. When he is not being followed round the wards of his hospital by flocks of adoring students, he runs a busy general practice. He has neither wife nor encumbrances. He charges his patients no fees. Finally, he is invariably a source of ignoble jealousy in his colleagues. I have never seen it explicitly stated, but I am convinced that he wears a fur-lined overcoat and travels first class on the railway. In this, indeed, he comes nearest to the true surgical tradition. Even the less wholly extravagant medical

creations of that gay exploiter of the half truth, Mr. Bernard Shaw, are but changelings and bear no more resemblance to the doctor than does a presentation portrait by a modern artist really depict the features of its defenceless subject. It would not be candid of me to maintain, however, that we are not ourselves somewhat to blame for the popular errors concerning us. The medical profession rarely speaks with an authentic corporate voice, though it is possible that a guileless public may so regard the sententious twaddlings of that modern Mrs. Harris, 'the Harley-street specialist' of the press. But there are other reasons which make it inevitable that we should be misunderstood. For instance, some of the most familiar words in the language have a special meaning for us; a meaning that has no currency elsewhere. Take that simple word 'evidence.' To us, this implies the concise statement of some fact of careful observation. To the lawyer, on the other hand, it means a statement, any old statement, uttered by any light-hearted gossip to whom the courts in their inscrutable wisdom may decide to listen. Finally, to the politician—but there are lengths to which candour may not be pushed, and before this audience I dare not utter the hearty monosyllables that alone are adequate to a definition. I will not go on elucidating the little differences that render us doctors such a puzzle to our fellow-men. In legislation and in jurisprudence to be incomprehensible is to command respect, and in modern art and poetry to be unintelligible is the hall-mark of true genius. Therefore, I hesitate to withdraw from our profession what of mystery still surrounds it, and content myself with giving you the toast of 'Our Guests.'"

Dr. Barnes, in responding, said that the ancient Egyptians had at their evening feasts, on such an occasion as the present, a memento in the shape of a mummy, and perhaps this Society regarded its guests as either examples of past success or as objects of potential experiment. Perhaps, as a guest, he was expected to tell members of the profession how they were judged from the outside. First, he wished to express the indebtedness of the whole community to the medical profession; especially because of the advances made in medicine and surgery during the last century. He had recently been reading the diary of a Somersetshire parson of a century ago, and was struck by the comparative softening of manners in the present day and the decrease of coarse viciousness; but he was most impressed by the alleviation of pain and suffering due to the progress of medical science and the establishment of our public hospitals. Surgery especially had been transformed by anæsthetics and aseptic practice, and progress in technique merited the term magnificent. The exactness and skill of British surgeons was inferior to none in the world. But though he and his relatives owed much to surgery, it must be regarded as a rough and rather crude way of dealing with the diseases of the human body. Was it a vain dream to look for the time when disease would be overcome either in Nature's way by increasing the resistance of the body to hostile organisms, or by remedying defects in internal chemistry? We were, as yet, only at the beginnings of knowledge concerning vaccines and vitamins. Laymen need not be troubled because doctors disagreed; in fact when they agreed too closely there seemed ground for suspicion. Medicine could not yet be called an exact science, and an exhilarating feature of scientific research was that one never knew in what region the next discovery would be made. At the end of the nineteenth century it seemed to many that the great era of physics had closed, yet the fact was that an even greater era than that of Faraday, Maxwell, and Kelvin was only just beginning; the period of those great minds was but the twilight before the dawn in the matter of present discovery and promise. At any time there might come in medicine a group of discoveries in biochemistry which would make it possible to confer on the body an immunity from ill-health such as now was enjoyed only by exceptional individuals. In spite of various kinds of disorder, the bishop declared, it was good to be alive. Never since the Golden Age of Greece had mental energy been more fertile than now. Naturally, old beliefs had crumbled and traditional standards of conduct had been sharply challenged, but, he declared, the gain outweighed the loss. Those who believed, as he himself did, that the Moral Law was part of the fundamental structure of the Universe would not fear its failure to withstand frank criticism; if religious dogmas proved to be untrue, let them pass. Dealing with the subject of eugenics, Dr. Barnes said that medical skill and public hygiene would ultimately be disastrous if they preserved inheritable mental and physical defects in humanity; it was known that dysgenic mutations could occur, in plants as well as in animals. Medical science destroyed the power of hostile environment, but usually it left inheritable characters untouched. The existence of mentally and therefore socially dysgenic mutations was a grave menace to the welfare of the community; already mental deficients constituted 1 per cent. of the community, and more accurate genetic knowledge was needed. A beneficent millionaire might well provide laboratories and a chair in genetics at our great universities. Investigations had shown that life had existed on the earth for quite 1000 million years, and it seemed that the intensity of the sun's heat had changed but little in that vast time; so that we could look forward to 500 million more years during which humanity could flourish on the earth. But civilisation, as measured by the art of writing, was not yet 10,000 years old; what, then, would happen in the inexhaustible future? Would medical science actually conquer disease, and would the descendants, enjoying this powerful brain and perfect body, create an Utopia? He could ask these questions without anxiety, and hear the answers without dismay, for he felt certain not only that man's permanent habitation was not on the earth, but also that his spiritual achievements were imperishable. In the average man as known to-day there was much that was worth preserving. In regard to aspirations and achievements, moral loyalties, love and service, his own faith was that they would not vanish as though they had never been; they were eternal, they were beyond time and space, for they were in that realm which the Christian had learned to call the Kingdom of God.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

BERLIN MEDICAL SOCIETY.

THE Berlin Medical Society celebrated its seventieth anniversary at a meeting attended by representatives of the Government Health Department, the City of Berlin, the Medical Faculty of the University, and of other medical societies. The president, Prof. Goldscheider, gave an account of the development of medical science during the past 70 years. The honorary secretary, Prof. Adam, described the history of the society which issued from a fusion of two smaller societies. The

number of members was at first 180 but is now about 1600, although many other special societies have meanwhile been created, of which the Society for Internal Medicine, founded by a number of physicians leaving the Berlin Medical Society in 1881, is the biggest. The society originally held its meetings in various places, but in 1892 rooms were hired in the Langenbeck House belonging to the German Surgical Association. Eventually the two societies together erected new premises called the Langenbeck-Virchow House which was inaugurated in 1915 during the war. The first president of the society was the celebrated ophthalmologist Græfe, who was succeeded by Langenbeck, Virchow, Senator, Orth, and Kraus. Prof. Goldscheider entered on office last year.

A CARDIAC HORMONE.

Prof. Zuelzer recently reported to the Berlin Medical Society on his clinical experiences of eutonone, a cardiac hormone discovered by him in the liver. Eutonone, he says, increases the muscular action of the heart—that is to say, the tone is increased. It has no cumulative action like digitalis, so that in severe cases six or eight injections may be given without undesirable symptoms. In healthy hearts which are still able to answer ordinary demands, though already unfit for great strain—for instance, in everyone over fifty—the reserve power is improved. Eutonone is also efficacious, it is claimed, in acute infectious diseases. Prof. Zuelzer said that during the last epidemic of influenza he treated in his hospital a series of pneumonia cases with no other cardiac remedy and found that in these cases the heart was undamaged, whereas in patients treated with other compounds cardiac murmurs often developed. Its administration is further appropriate before severe operations and for training; after being treated with eutonone fast runners showed greater efficiency, less fatigue, and no cardiac palpitations. By its dilating action on the coronary arteries eutonone is useful in angina pectoris; most of the cases of moderate severity lost their pains within two or three weeks. In chronic myocarditis the destruction of the heart muscle cannot, of course, be repaired, but the reserve power of intact parts of the heart muscle is strengthened so that the patients loose their troubles. Dyspnœa disappears and patients who came to the hospital with severe orthopnœa were able to sleep on the same or the next night without morphia.

PSITTACOSIS.

The epidemic of psittacosis which broke out some time ago in Germany led to severe measures which reflected great nervousness in official and medical circles as well as among the lay public. As a result of this nervousness a consignment of 180 valuable parrots was destroyed by gas under the order of the Hamburg health authority without any previous examination, although none of them showed any symptom of disease. The proprietor of the parrots has now brought an action for damages against the city, alleging that there was no reason to destroy the parrots at once; even if they were suspected, quarantine would have been sufficient. He says that the manager of the celebrated Hagenbeck Zoological Garden in Hamburg intended to buy the parrots after their arrival which shows that there was no suspicion that they were ill.

STATISTICS OF RHEUMATISM.

Statistical records show that of the invalids in the Berlin municipal hospitals for the incurable 7 per cent. suffer from chronic rheumatism. As to acute cases it is stated that in the Charlottenburg municipal hospital, for instance, 4·3 per cent. of all the patients received during the last three years suffered from rheumatic diseases. The number of 7 per cent. invalids is much smaller than in other countries—e.g., 9 per cent. in Sweden, 12 per cent. in Denmark, and even 18 per cent. in England are recorded. Invalidity began in 66 per cent. before 60, in 38·5 per cent. before 50, and in 15·5 per cent. before 40 years of age. The average duration of the illness is in Berlin 15 years and of invalidity 10 years. In the city of Berlin the expense of the individual arthritic invalid amounts to 14,500M, and for all the rheumatic invalids together to 3,295,000M. A familial history of the disease was obtainable in 35 per cent.; exogenic causes were chills, infection, and trauma. Among women working with laundry or in draughty places like market halls increases liability to rheumatism. Among men, the rheumatic occupations are those of stoker, baker, mason, and coachman.

A NEW SANATORIUM FOR LUPUS PATIENTS.

There are very few sanatoriums for lupus in Germany compared with the great number of sanatoriums for tuberculosis of the lungs and of the bones and joints. There is, indeed, only one sanatorium of the kind at Giessen under the direction of Prof. Jesionek, the dermatologist of Giessen University; the second sanatorium for lupus at Graudenz, Western Prussia, became Polish after the war. The German committee for the combat of tuberculosis has now erected a new sanatorium in Müncheberg near Berlin. At the opening the president of the German Health Office, Prof. Hamel, said that lupus is much more widespread in Germany than is generally believed; in Westphalia alone 2000 lupus patients, and in all Germany about 50,000 are registered. The new sanatorium has arrangements for modern treatment, especially for the different irradiation methods and for the Gerson diet. The number of beds is 30 for adults and 15 for children.

RADIOGRAPHY IN OBSTETRICS.

Dr. Baumann reports on the value of radiography to the obstetrician, especially when manual examination fails. By radiography the position of the fœtus, the disproportion of the head and the pelvis, the success of turning, twin pregnancy, deformities of the fœtus, such as hydrocephalus and anencephalus, can be made visible. In narrow pelvis not only the size of the fœtus is ascertained but also the size and the form of the head and its presentation.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

STATISTICS OF B C G.

IN a communication made to the Académie de Médecine on Nov. 4th, Prof. Calmette brought the statistics of B C G up to date with certain figures of exceptional interest. At the present time every seventh infant born in France is vaccinated with B C G—i.e., 8000 to 9000 infants every month. The total number of persons thus vaccinated in France up to Oct. 1st, 1930, is 280,000, and this figure does not include 112,000 infants vaccinated in the French colonies and protectorates. About an equal number have been thus vaccinated outside French territory, and every European country, with the exception of Austria, Great Britain, and Portugal, has introduced B C G vaccination. The countries in which it has been most extensively adopted and yielded instructive results are Greece, Poland, Roumania, Spain, and Sweden. In Roumania more than 60,000 infants

have been vaccinated. In Sweden, in the province of Bothnia, where there is much tuberculosis, 4009 infants were vaccinated between September, 1927, and May 1st, 1930. In the same place and period, it is stated, there were 8342 infants who lived under the same conditions and who, not being vaccinated, served as controls. During these three years, the mortality for the non-vaccinated was 22·2 per cent., whereas that for the vaccinated was only 6·6 per cent. Prof. Calmette presented a table of statistics gleaned from Germany, Belgium, Bulgaria, Spain, Greece, Hungary, Poland, Roumania, Russia, Sweden, Czecho-Slovakia, Yugoslavia, the Argentine, Brasil, Canada, U.S.A., Mauritius, and Uruguay. As he pointed out, a comparison of the tuberculosis death-rates among vaccinated and non-vaccinated infants is apt to be misleading, because it is exceptional for the cause of death to be determined by a doctor, whereas if a comparison is made of the general death-rates in the two groups, every death from tuberculosis is counted in one or other of the two groups. Another interesting comparison was that made between two different age-groups—the first month of life and the last eleven months of the first year of life. B C G vaccination not having had time to be effective during the first month of life, no difference could yet be expected in the death-rates in the vaccinated and non-vaccinated groups. But there should be a difference in the second age-period in favour of the vaccinated if B C G possesses the merits claimed for it. The correctness of this hypothesis, said Prof. Calmette, has already been proved in Bulgaria, where the death-rates in the first month of life have been approximately the same for the vaccinated and non-vaccinated, whereas in the second age-period, from one to twelve months, the death-rate was 11·4 per cent. for the non-vaccinated and 5·6 per cent. for the vaccinated. In France, in the Department of Guebwiller (Upper Rhine) there were 478 births in 1925; none of the infants born in this year was vaccinated. Everyone of the 445 infants born in 1928 was vaccinated with B C G. The death-rate during the first month of life among the infants born in 1925 was 2·7 per cent.; for the infants born in 1928 it was 2·76 per cent. But in the age-period from one month to a year, the 1925 death-rate was 5·1 per cent., the 1928 death-rate only 1·37 per cent. Though it might be argued that the mothers who got their infants vaccinated would also in other respects care better for them than the mothers who did not get their infants vaccinated, this possible source of error can be eliminated in the case of the dispensary infants. These (constituting the majority) were under the supervision of visiting nurses who would devote equal care to the vaccinated and the non-vaccinated.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

THE NEW RECTOR OF ABERDEEN UNIVERSITY.

THE medical profession may well be gratified that the students of Aberdeen University have chosen as their Rector Sir Arthur Keith, whose name is one of the most brilliant on the list of medical graduates of the University. It has not, I believe, happened before that two graduates of Aberdeen occupied the distinguished posts of Chancellor (Lord Meston) and Rector (Sir Arthur Keith). They both won their spurs away from Aberdeen; but the University has not lost sight of them.

AN EDUCATIONAL EXPERIMENT AT DUNDEE.

Dundee Education Committee have decided to try an experiment for a year with the unemployed youth of the city. It was found that out of 82 boys wholly unemployed, only 4 were attending evening classes and of 111 girls, only 6. It is now proposed to spend approximately £1000, of which 75 per cent. would be paid by the Ministry of Labour, on providing a course for girls. The subjects for the girls suggested by the director of education include cookery, needlework, English with history and geography, based on the posters of the Empire Marketing Board, writing of letters, calculation of bills, physical exercises with team games, singing, and also lectures on personal hygiene and mothercraft. A corresponding sum is to be spent on the lads' course. Their course would include benchwork, measuring and weighing, and occasional lectures on physiology and personal hygiene in place of the domestic subjects in the girls' course. These institutes will enable the Health Committee to keep touch with an important section of the young community.

HYGIENE UNDER OTHER NAMES.

The medical mind is so occupied in blazing new trails in preventive medicine that some already in use are apt to be forgotten. Mr. Gilzean, convener of the general purposes committee of Edinburgh town council, says that in Edinburgh the attendances at the baths last year were 750,000, the total including 75,000 school-children who were admitted at a nominal charge. In the poorer quarters of the city the public wash-houses were used last year by 640,000; the income was £17,000, and the expenditure £22,000. For recreation, there were 58 parks, 35 playgrounds, 79 football pitches, 4 rugby pitches, 6 hockey pitches, 8 cricket pitches, 9 golf-courses, 35 bowling-greens, 80 tennis-courts, 11 putting-greens, 3 quoiting-courses. The gross expenditure on parks was £74,000. The income from various sources amounted to £19,000, leaving a charge on the rates of practically £1000 a week. He thought that this expenditure was justified up to the hilt. Last year in connexion with organised games under the direction of the public parks committee over a million persons took part.

These facts, though not directly medical, indicate how the concept of health preservation has infected the whole community. No doubt other cities can show equivalent figures, but it is worth putting these on record since an active layman has taken the trouble to procure them. No one can trace the effect of these activities in any death-rate; but that only means that the death-rate is a very imperfect measure of the progress of preventive medicine.

CLINICS FOR THE BLIND.

The standard of certification of the blind varies widely in different places, and in order to secure more uniformity the Department of Health recommends that local authorities should arrange for the establishment of clinics on a regional basis, as in the parallel case of hospital services, on the Glasgow model. The Department considers that, in addition to the Glasgow clinic, there should be four regional clinics at Edinburgh, Dundee, Aberdeen, and Inverness. With a view to securing uniformity, the Department proposes to convene a meeting of ophthalmic specialists as soon as these surgeons have been appointed to the clinics. On April 1st of this year there were 8897 blind persons in Scotland, or one to 549 of the population. In the case of blind persons between 50 and 70 years of age, the corresponding proportion was 1 to 1183. In areas where the incidence

of blindness generally, or the incidence in the 50–70 years age-group, is above the ratio for Scotland as a whole, it may be desirable to re-examine all the registered blind, or at least the doubtful cases. In these matters the services of a properly organised regional clinic would prove indispensable.

SCOTTISH CRIME.

There seems to be a steady decrease in the number of persons proceeded against in the Scottish criminal courts. In 1929 the number dealt with for cruel and unnatural treatment of children fell to 193, compared with 617 in 1914. The number proceeded against for drunkenness and breach of the peace was the lowest since 1918. The general decrease was seen mainly in crimes against property without violence and in miscellaneous offences. Only one person was sentenced to death in the year, and he was reprieved; on the other hand those sentenced to penal servitude numbered 51, the highest number since 1922. The number of persons dealt with under the Probation of Offenders Act, 1907, has again increased, and stands at 3918 in 1929, which is the highest since 1917. This is held as affording some ground for satisfaction.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

GALWAY BOARD OF HEALTH.

THE expected result has followed on the recent inquiry made by the Department of Local Government and Public Health into the working of the County Galway Board of Health. The Minister has, by sealed order, dissolved the Board of Health, and transferred its powers and duties to a commissioner appointed for the purpose. In the letter announcing this decision the Minister states that for some considerable time he had grave doubts of the capacity and efficiency of the Board. He gives several examples of this lack of efficiency. The Board had failed, in spite of repeated representations, to provide suitable hospital accommodation in Clifden and Ballinesloe. Some months ago the Board committed itself to a policy of abrogating its authority as regards disciplinary questions concerning dispensary medical officers. More recently it had opposed the policy of reorganisation of public health services consequent on Acts of the Legislature. In particular it had obstructed the carrying out of the functions of the county medical officer, by refusing to appoint an assistant medical officer and two public health nurses. As a result the county tuberculosis scheme had partially fallen into abeyance in the past few months, with most unsatisfactory consequences to patients who had been under treatment. In view of the attitude of persistent inertia adopted by the Galway Board of Health, the Minister had little option as to his action. Moreover, experience of administration by paid commissioners in all areas in the Irish Free State where it has been tried has proved uniformly successful. The most notable example is the city of Dublin. Under commissioner rule there the social services were widely extended, and many overdue reforms carried out, while at the same time the rates were reduced by about 25 per cent.

DAMAGES AGAINST A COUNTY MEDICAL OFFICER OF HEALTH.

An unusual claim was made against Dr. Maguire, county medical officer of health, before County Court Judge Moonan at Roscommon last week. Two members of a family named Campbell claimed damages amounting to £200 against the county board of health and the medical officer for the destruction of clothes and other property. It was given in evidence that one occupant of the house had died of typhus fever, and another, suffering from the same disease, had been removed to hospital. The medical officer of health proposed to remove certain clothes and other articles for disinfection. A third member of the family, Patrick Campbell, appealed to the medical officer not to remove the clothes for disinfection, as such a proceeding would cause unnecessary publicity, and would injure the family business; he asked that the infected articles should be burned. He went so far as to give the medical officer an indemnity against any claim if he should agree to burn the articles. This course was adopted. The plaintiffs maintained that Patrick Campbell had no authority from them to authorise the destruction of their property. For the defence it was urged that Dr. Maguire was merely carrying out his statutory duties, and that he believed that Patrick Campbell had full power to act for the family. The judge dismissed the case against the Board of Health, but gave decrees for £90 and £75 respectively against Dr. Maguire, expressing the hope that the Board would not allow their medical officer to be at any personal loss.

APPOINTMENTS IN DUBLIN HOSPITALS.

Mr. James Owens has been appointed surgeon to Mercer's Hospital, in succession to the late Mr. R. C. B. Maunsell. Dr. L. Abrahamson and Dr. James O'Connor have been appointed honorary physicians to the House of Industry Hospitals, in succession to Dr. J. F. O'Carroll and Dr. G. E. Nesbitt, resigned.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced: Surg. Comdr. J. F. Ainley to *Victory*, for R.N. Hospital, Haslar; Surg. Lt. Comdrs. R. W. Higgins to *Ganges* and A. A. Pomfret to *President*, for three months' post-graduate course; and Surg. Lt. R. C. May to *Harebell*.

ROYAL ARMY MEDICAL CORPS.

Maj. R. H. Lucas retires, receiving a gratuity.
Maj. P. S. Stewart retires on retd. pay.
Lt. D. A'Brook resigns his commn.
Lt. (on prob.) T. M. Corcoran, from the secd. list, is restd. to the estabt.

ARMY DENTAL CORPS.

Capts. J. McL. Foreman and J. Wren to be Majs.
Lt. A. Brazenor to be Capt.

ARMY RESERVE OF OFFICERS.

Maj. J. B. Meldon, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.
Capt. J. A. G. Burton, from Supp. Res. of Off., to be Capt.

TERRITORIAL ARMY.

Maj. H. G. Wimbush (late M.G.C.) to be Lt., and relinquishes the rank of Maj.
Capt. G. E. Lloyd to be Maj.
Lt. H. B. Stallard resigns his commn.
J. E. Crooks to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. O. Teichman, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

ROYAL AIR FORCE.

The undermentioned Flight Lts. are transferred to the Reserve, Class D (ii): M. Clancy and C. P. O'Toole.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. R. Dutton retires.

PUBLIC HEALTH SERVICES

THE TREATMENT OF VENEREAL DISEASES AMONGST SEAMEN.

By A. O. Ross, M.D., D.P.H.,
MEDICAL OFFICER, SEAMEN'S DISPENSARY, LIVERPOOL.

DURING the past few years the control of venereal disease among seamen has given rise to much discussion, culminating in the resolutions which were adopted by the second conference on the Health and Welfare of Merchant Seamen held at Geneva in October, 1929. These resolutions call upon the League of Nations to evolve a system whereby treatment of venereal disease in seamen shall be regularly carried out, both at sea when a surgeon is carried and at clinics on shore. The main reason for the necessity of treatment at sea is the economic one that a seaman earns his pay by going to sea and rapidly becomes destitute should he remain ashore.

From six years' experience as a whole-time medical officer in charge of a venereal diseases clinic dealing with seamen of all nations, and whose attendances number over 50,000 annually, I propose to give the outline of a plan for treatment, based on actual contact with the problem.

Gonorrhœa.

Acute gonorrhœa up to six weeks can be treated as efficiently at sea as on shore by means of urethro-vesical lavage, provided the lavage solution is kept weak and that the temperature is within the limits of 100° to 110° F. The installation of a common irrigator in ships demands that one person is made responsible for the sterilisation of the nozzle and for the cleanliness of the reservoir and tubing. Oxycyanide of mercury is the irrigating solution of choice in a dilution of 1/12000 to 1/8000 because of its cleanliness. In conjunction with euflavine gr. ½ by mouth 3 times a day it has been used as the routine lavage solution in this clinic for four years, and in the majority of cases the urine is rendered clear within one week. This compares favourably with other lavage solutions which commonly take at least twice as long to achieve that result. The use of the small hand syringe should never be permitted as there is abundant evidence to prove that this instrument is responsible for the bugbear of chronic anterior folliculitis.

The later stages of gonorrhœa are best dealt with by the shore specialist, and the necessary time can usually be spared by the seaman between trips. The danger of issuing irrigators to ships is that the men will imagine that they are cured and will not report at the shore clinic. Some men therefore who would have attended till cure was completed at a shore clinic may by reason of this false sense of security become potential dangers to the uninfected community.

In ships carrying surgeons there is rarely any reason for the man infected with gonorrhœa to stay ashore even in the chronic stage, provided the ship's surgeon makes use of the medical officer of a clinic as a consultant and bacteriologist combined. In this connexion it is well to remember that gonorrhœa and syphilis frequently coexist, the syphilis being latent in about 5 per cent. of cases. The need for the serological examination of the patient's blood early in the disease and again four months later should never be forgotten. Again, it might be well for all supposedly cured gonorrhœa cases to be referred to a shore clinic at the end of each voyage. In this way, two heads being better than one, the number of potential carriers of the gonococcus could be reduced.

Form V44 should be carried in the medical stores and used when referring any patient to a clinic, or transferring a patient to another ship or to hospital for in-patient treatment.

Syphilis.

In ships without surgeons a penile ulcer should be treated with a solution of normal saline (as described in the Ship Captain's Guide) and the advice of a competent medical officer sought as soon as port is entered. Secondary and tertiary syphilis can be treated orally, but here again the danger is that disappearance of symptoms may lead the untutored to imagine that the disease has been cured. The captain might make it his duty to report all cases of venereal disease occurring on the voyage to the inspector of the port sanitary authority on arrival at the home port. The inspector could then interview the men individually and tactfully urge them to attend at the shore clinic.

In ships with surgeons the treatment of syphilis (diagnosis confirmed if possible by micro-examination and serological tests) depends upon the capability of the surgeon. In all cases intramuscular administration of bismuth should be possible, but the provision of any form of arsenobenzol is of doubtful value. If a surgeon is not skilled in intravenous therapy it is unlikely that he is acquainted with the early signs of arsenobenzol intolerance, and thus to issue sulfarsenobenzol might result in serious trouble in patients with idiosyncrasy to arsenobenzene preparations, though at first sight the provision of sulfarsenobenzol for intramuscular use seems to present an easy way out of the difficulty. Where the ship surgeon is trained in the administration of this preparation a supply should be carried and used according to one of the well-defined courses of treatment in use on shore. Each dose of arsenobenzol and bismuth should be entered in the patient's V44 which should be given to him on paying-off, or on change of surgeon.

Our larger shipping companies have it in their power to demand that any surgeon entering the service of the company shall hold a certificate of proficiency from a clinic of standing—i.e., a clinic which has at least 500 fresh cases of venereal disease per annum—vide Ministry of Health Statutory Rules and Orders, 1930, No. 69—and eventually the ships will become staffed with surgeons who are capable of treating any case of syphilis in the ship's company.

There remain for consideration the men who come ashore for treatment for syphilis—i.e., from ships where bismuth alone has been administered or where no surgeon is carried. These men certainly want to spend as little time as possible on shore, and thus intensive treatment is indicated. I have been using the method originally used by Parnell and Fildes in the Royal Naval Hospital at Haslar in 1917–19. In addition to the purely N.A.B. course of 4·2 g. I have added intramuscular bismuth and simultaneously have increased the N.A.B. to 5·7 g., although I believe that 4·2 g. of N.A.B. give results just as good. A scheme is here given.

Day.		Grammes N.A.B.	Grammes Bi.
1	..	0·45 + 0·6 g. sodium thiosulphate	0·30
4	..	0·6 + ,, ,, ,,	,,
8	..	*0·45 + ,, ,, ,,	,,
11	..	*0·6 + ,, ,, ,,	,,
15	..	0·45 + ,, ,, ,,	,,
18	..	0·6 + ,, ,, ,,	,,
22	..	0·45 + ,, ,, ,,	,,
25	..	0·6 + ,, ,, ,,	,,
Short course			
29	..	Nil.	
32	..	0·75 + ,, ,, ,,	,,
36	..	Nil.	
39	..	0·75 + ,, ,, ,,	,,

* After the third and fourth doses, symptoms of intolerance are to be especially looked for, and before administering the dose the Abelin reaction should be performed.

There are two great advantages in this scheme which in therapeutic effect is at least equal to any other course.

1. The time spent ashore is 25–39 days.
2. The result of this course on the types of syphilis

as expressed in terms of the Wassermann reaction and its relapse time are here tabulated, and it will be noted that one can give a very definite prognosis that in the earlier cases of syphilis (A. B. C. types) the Wassermann relapse, should it occur, will not appear till after the six months, and thus in times of financial stringency a man can go to sea for six months before returning for a second course.

—	W.R. before treatment.	Duration of treatment.	% Neg. at 3 mths.	W.R. relapse.
A. Sero-neg. primary .	—	25–39 days.	100	1 year at least
B. Sero-pos.	++	..	100	9 mths. ,,
C. ,, ,, secondary	++	..	95	6 ,, ,,
D. ,, ,, late ..	++	..	70	Indefinite.

It is essential that this course be followed sedulously and not modified. Any irregularity in dates nullifies the prognosis. Similar courses should be given every three to six months until a minimum of 30 intravenous injections has been given.

Commentary.

The routine treatment of acute gonorrhœa can be accomplished at sea in all ships if irrigation apparatus and intelligent supervision are provided. The treatment of chronic gonorrhœa in ships carrying surgeons can be continued at sea provided advantage is taken of the advisory and bacteriological services of shore clinics. The complete treatment for syphilis can be given at sea provided that ships' surgeons are trained in giving intravenous novarsenobenzene and a full record is kept of the case on Form V44 which should remain in the possession of the patient. Intramuscular bismuth can be given by surgeons otherwise unskilled in the treatment of syphilis, and at the end of the voyage the patient should be transferred for novarsenobenzol treatment to a shore clinic (V44 being issued).

In ships without surgeons the instructions given in the "Ship Captain's Medical Guide" should be followed and advantage taken of the advice of shore clinics (which can be obtained through the port sanitary inspectors) until a home port is reached and the ship's company is paid off. The captain or ship's surgeon should never give the patient reason to believe that he is cured, without clinical and bacteriological proof.

Shore clinics may help by offering seamen intensive treatment for a period of four to six weeks every three to six months until the minimum of 30 intravenous novarsenobenzol injections has been given.

I have to thank Dr. A. A. Mussen, Medical Officer of Health, City and Port of Liverpool, for permission to publish this article.

MENTAL HOSPITAL REPORTS.

The SOUTH YORKSHIRE MENTAL HOSPITAL at WADSLEY, near SHEFFIELD, had 1912 patients on the books on Dec. 31st last. There was a recovery-rate of 37·6 per cent. and a death-rate of 10·5 per cent. Autopsies were held on 91·9 per cent. of the fatal cases. Many of those discharged recovered were sent out first on a trial period with money grants. New open-air dormitories became available during the year, but the institution is still crowded in the day-time. There were four cases of typhoid, two of diphtheria, three of erysipelas, one of dysentery, and one of scarlet fever, and an epidemic of influenza with some pneumonia. Thirty-two cases of tuberculosis are under care. The visiting surgeon saw a number of patients and performed several operations. The X ray department is now in full use, and a new sanatorium for cases of tuberculosis and dysentery is being built. During the year 24 men had parole within the grounds and another ten outside it. The out-patient clinics at the Sheffield general hospitals recorded 125 new cases and 22 after-care cases at the Royal Infirmary and a total of 105 cases at the Royal Hospital. The laboratory carried out a large number of routine investigations, including a systematic search for typhoid carriers and a routine Widal test on all new admissions. The Meinicke reaction is also tested on all new cases. General paralytics are treated by induced malaria; of the 21 inoculated during the year five have been discharged and five have improved but are not fit for discharge. Three cases are under treatment by sulphosin. There are 44 post-encephalitics, nine new cases having been admitted during the year. In the ultra-violet light department 39 cases were treated, including a number of skin diseases. The visiting dentist now attends weekly and saw 442 patients last year in the new surgery. During the year 11 attendants and nine nurses obtained their R.M.P.A. certificate, bringing the total to 63 attendants and 32 nurses certificated.

The ROXBURGH DISTRICT BOARD OF CONTROL had 384 patients resident in its institution on May 15th last, an increase on the preceding year. In about one-third of the admissions there was no hope of recovery, yet there was a recovery-rate of 34 per cent. The death-rate was 7·2 per cent. and 11 post-mortem examinations were made. The general health was good and there were no epidemics. A dental surgeon has visited regularly and seen all new cases. Occupational therapy has been commenced and 116 men and 89 women have been in regular employment. There are, however, a large number of senile cases and 61 defectives.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 15TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 107 (last week 92); scarlet fever, 2377; diphtheria, 1491; enteric fever, 45; pneumonia, 831; puerperal fever, 50; puerperal pyrexia, 128; cerebro-spinal fever, 8; acute poliomyelitis, 10; acute polio-encephalitis, 1; encephalitis lethargica, 11; dysentery, 7; ophthalmia neonatorum, 98. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 18th–19th was as follows:—Small-pox, 186 under treatment, 1 under observation (last week 161 and 6 respectively); scarlet fever, 1923; diphtheria, 2207; enteric fever, 15; measles, 85; whooping-cough, 109; puerperal fever, 21 (plus 6 babies); encephalitis lethargica, 121; poliomyelitis, 1; "other diseases," 35. At St. Margaret's Hospital there were 13 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 23 (0) from measles, 4 (0) from scarlet fever, 13 (0) from whooping-cough, 39 (9) from diphtheria, 55 (17) from diarrhœa and enteritis under two years, and 25 (5) from influenza. The figures in parentheses are those for London itself, against which it may be noted that there was no single death during the week from either small-pox, enteric fever, measles, scarlet fever, or whooping-cough.

The fatal cases of enteric fever outside London were reported from Wigan and Sheffield. Measles accounted for 6 deaths at Hull, 4 at Bristol, 2 each at Birmingham and Newcastle-on-Tyne. Leeds reported 2 deaths from whooping-cough. Three fatal cases of diphtheria were reported at Liverpool and at Leeds. Diarrhœa accounted for 6 deaths at Liverpool, 5 at Sheffield, and 3 at Birmingham.

The number of stillbirths notified during the week was 279 (corresponding to a rate of 42 per 1000 births), including 55 in London.

CORRESPONDENCE

PREVENTION OF SCARLET FEVER IN SCHOOLS.

To the Editor of THE LANCET.

SIR,—The paper by Dr. J. A. Glover and Dr. F. Griffiths which appeared in your journal on Oct. 11th, under the title An Outbreak of Scarlet Fever at a Preparatory School, will lead some to believe that very little can be done to check an outbreak of scarlet fever in a school. The authors are medical officers from the Ministry of Health and it will be assumed that they speak with knowledge and authority. It is to correct this impression of our helplessness in face of an outbreak of scarlet fever in a school that I venture on writing this note.

What do the authors say? Shortly, it is this. In a modern school house near the sea, with about 50 boys, ages varying from 8–14 years, scarlet fever breaks out, seven cases occurring between Nov. 12th and 21st; each patient is promptly removed to hospital. No more cases occur for more than two months, but about ten days after the reassembly of the school after Christmas four more cases are found in rapid succession. The school authorities then seek the advice of the Ministry of Health, especially on the question of preventing further spread of the disease. The authors did not advise immunity methods, and for the following reasons: the production of passive immunity by injection of scarlet fever antitoxin is not recommended on the ground that this immunity is too evanescent for use in a boarding-school and because the injected persons become sensitised to horse serum. (This last is of little practical significance for subsequent serum administration.) Active immunity by the Dick method, they say, takes too long and is too uncertain. The small experience of this method in English schools has not been encouraging (it would be interesting to know what their record of this is), though for the use of a hospital staff it may be very valuable.

Instead they undertook an elaborate bacteriological investigation, swabbing on three separate occasions increasing numbers of boys and staff (i.e., Jan. 31st, 19 boys; March 14th, all the boys remaining at school and certain of the staff; May 21st, all the boys and all the staff), and found on each occasion a number of carriers. Profuse carriers were isolated.

In spite of this the epidemic continued on its course unabated. Eighteen more cases occurred in the Lent term, and four cases in the summer term; in all 33 boys contracted scarlet fever out of about 50, so that we can take it that the disease exhausted all the available susceptible material, the remainder becoming immunised. The practical result of the authors' advice to this school as regards stopping the epidemic was thus insignificant; theoretically this investigation has a scientific interest, as it illustrates by bacteriological methods modes of spread of scarlet fever of which we were aware previously only clinically.

Now let us see what the Dicks themselves say about preventing an outbreak of scarlet fever at school. I quote from Schamberg and Kolmer's "Acute Infectious Disease," 1928:

> The Dicks have recently (*North-west Med.*, 1926, xxv., 200) stated "that the skin test for susceptibility to scarlet fever used in connexion with preventive immunisation with the toxin and the prophylactic administration of antitoxin, makes possible the control of scarlet fever epidemics. In an institution where adequate facilities for throat and nose cultures are available it is possible to get the *epidemic under control within 48 hours.*"

They then proceed to describe the procedure which is exactly similar to the one recommended for controlling a diphtheria outbreak.

I had some personal experience with this method, but applied without the bacteriological investigation at a girls' day school in 1928; this was a good class high school and preparatory school of 250 girls in Salford (ages 5–17 years). Fifteen cases had occurred in the autumn term, and the usual methods of disinfection, isolation, inspection of milk, &c., were undertaken without checking the disease. At the end of January I was approached and Dick-tested 135 girls—their parents having given consent—and found 86 of them susceptible to scarlet fever; 78 of these were inoculated (the other eight refused to go on) at weekly intervals with 500, 2000, and 8000 skin test doses of scarlet fever prophylactic, the more strongly marked reactors getting 250, 1000, and 5000 S.T.D. Of these girls, 73 were retested three weeks later after the third dose and 47 were found to have become negative; 26 still gave positive reactions, but these were considerably fainter. Eighteen of these were given a fourth inoculation. In the Lent term there were only two more cases of scarlet fever in the school, in the group which was not tested. In this school just over half the girls were tested; this work was undertaken, as it happened, at the time of the Australian accidents with diphtheria prophylactic, and I had to address the parents on the day the news was in the daily papers. I have no doubt that with more efficient canvassing the proportion of consents could be increased. But even so, although of course there were probably a number of susceptibles left in the 114 girls who were not tested, the proportion of immunes in this group would in all probability be higher than in the group tested, for the reason that most of the girls who had had scarlet fever previously would fall into this group (the girls who had scarlet fever in the previous term were in this group). We can take it then that the majority of susceptibles were rendered immune and that the whole school population (herd) became much more resistant to the spread of the infection, so that if a certain equilibrium had been reached—i.e., cases occurring at intervals—the disease thus spreading slowly, the raising of the resistance of the school herd would tend to upset these conditions in the direction of checking the spread of the disease. It is thus not so important as may appear at first sight to immunise everybody in a population for the purpose of checking an outbreak of a disease, as it is to immunise even a part of it. The larger the proportion of the whole it is, of course, the better will be the result.

I am, Sir, yours faithfully,

D. EDGE,
Medical Superintendent, Ladywell Sanatorium (Infectious Diseases), Salford.

Nov. 24th, 1930.

A SOCIETY OF PHYSICAL MEDICINE.

To the Editor of THE LANCET.

SIR,—The statement on p. 1147 of your last issue that "on Nov. 14th, a society was formed, but its proposed policy did not satisfy a considerable group of those affected" does not convey the correct facts. As the Society constituted on Nov. 14th made no statement of policy, there could be no question of its policy not satisfying any group. Both at the publicly advertised meeting on Nov. 14th (which was

attended by about 40 representatives of every branch of physical medicine), and at the previous meeting on Oct. 24th, when the resolution to form a Society of Physical Medicine was first taken, the question of the Royal Society of Medicine was fully discussed. It was agreed at both meetings by the large majority that to establish an independent and individual society was the only satisfactory and practical course. This policy is, perhaps, not in agreement with the wishes of those general physicians who have little more than an academic interest in physical medicine, but it *is* the policy favoured by the great majority of the younger and active physiotherapists in whose hands lies the future of this important branch of medicine. It is, therefore, the policy that must prevail.

I am, Sir, yours faithfully,

R. KING BROWN,
Acting Hon. Secretary, the British Society of Physical Medicine.

Nov 21st, 1930.

VALUE OF RAMISECTION IN CASES OF SPASTIC WEAKNESS.

To the Editor of THE LANCET.

SIR,—The report on Ramisection in THE LANCET of July 19th, under the authorship of a number of distinguished medical men, is so full of inaccuracies that a reply is demanded.

In the first place the authors have not worried about accurate references and have attributed the operation of ramisection to J. I. Hunter and N. D. Royle. This is incorrect. I published my first paper on Jan. 26th, 1924, on A New Operative Treatment of Spastic Paralysis and its Experimental Basis. Hunter's contribution to the experimental side of this work was not made until nine months after the operation had been performed on the human subject. His paper, The Significance of of the Double Innervation of Voluntary Muscle Illustrated by Reference to the Maintenance of the Posture of the Wing, was published on June 14th, 1924. These are the original references and are found in the *Medical Journal of Australia*.

Next let me deal with adverse reports. The operations of sympathetic ramisection are difficult and require special knowledge of the sympathetic nervous system. This is possessed by few and the results of the trial operations are necessarily disappointing if the correct tissues are not divided. Bankart, for example, has reported in the *Journal of the Royal Society of Medicine* the results of ramisection in which he failed in a number of cases to get even vaso-motor changes. The explanation is obvious.

The next point is that I chose the worst patients for operation and in this remark I am supported by my friend Dr. Gordon Pugh of Queen Mary's Hospital, Carshalton, where my operations were performed. Now let me deal with the patients.

Case 1 of the report.—This patient had had encephalitis lethargica and exhibited the sequelæ including athetosis. The latter is not mentioned in the report. On this patient I performed my 2nd operation of sympathetic ramisection and this I have discovered since is not a suitable procedure for athetosis. I recently (Oct. 6th, 1928) introduced a new operation, thoracic sympathetic trunk section, by which all the sympathetic fibres going to the upper limb are divided in addition to having effects in the cerebrum.

Case 2.—This patient had had encephalitis lethargica and fell backwards when she attempted to walk. The operation of "double lumbar ramisectomy" is described as producing no improvement, yet she was walking according to the case records on Feb. 25th, 1928, and further could walk comfortably sometimes. She retrogressed subsequently on account of the progressive cerebral sclerosis associated with encephalitis, but that does not justify the statement that no improvement appeared.

Case 3.—This patient was a boy with left spastic hemiplegia of which the onset was sudden. Flaccid paralysis followed after a restless night and developed into spastic paralysis. The patient could not run. He could not use his hand and his thumb was tightly flexed in his palm. The day following the operation (May 11th, 1927) this patient could control voluntarily his fingers and thumb and could supinate eight days later. Yet the results are attributed to re-education. He was able to run in July, 1927. On Feb. 7th, 1928, Mr. Trethowan said, according to case-history, that the hand was very good. Such results in re-education of spastic paralysis have never been obtained in any of the clinics I have visited in various parts of the world.

Case 4.—This patient had severe spastic paraplegia with loss of voluntary control of his lower limbs. He had previously had obturator neurectomy and adductor tenotomy performed by Mr. Elmslie without results so was, apparently, not a good subject for a trial operation. Ramisection produced immediate improvement in range of movement and alteration in reflexes while I was in Carshalton, but these are not mentioned in the report.

Case 5.—This patient was seen by Mr. Trethowan who said he presented "a not very bad case of spastic quadriplegia, able to walk with a little help." The important point is that the patient was unable to walk before operation and walked unaided three weeks after ramisection. The report goes on to say "there is no evidence to show that bilateral lumbar ramisection in this case produced any result, such improvement as was ultimately seen being accounted for by the lengthening of the tendo Achillis on both sides which was subsequently performed." When I saw this patient in October, 1930, I found that the lengthening of the tendo Achillis had led to a severe double talipes calcaneo-valgus. The patient has thus lost the support of the calf muscles, cannot raise his heels off the ground, and had consequently re-lost his balance. The necessity for lengthening the tendo Achillis in this patient was disputed by the signatories when I said it should be done. Now it as been done with what the committee calls "improvement" but what I would classify as a calamity. The patient now uses hip and knee muscles well but the support at the heel is lacking.

Case 6.—I saw this patient also. She had athetosis and as such was not suitable for my old operation of sympathetic ramisection. In spite of that she has improved even with regard to opening her hand.

Finally, the opinion is expressed in the report that "the diminution of tone was no more than may be seen after *any* major surgical procedure with post-operative shock." I simply ask the signatories which operation in the lumbar region produces a diminution of tone in the lower limbs and for what length of time. My first patient exhibits changes in tone in the limb on side of operation seven years after operation. Surely the committee does not infer that he still has surgical shock?

Very sweeping conclusions are drawn from six cases. Surely it would be more advantageous for the committee to defer judgment until they had examined a greater number of patients. I have seen the results of approximately 600 operations and I would refer any honest seeker after truth to my paper in a recent number of the *British Medical Journal* on the results of ramisection as experienced by my patients.

I am, Sir, yours faithfully,

N. D. ROYLE.

Nov. 15th, 1930.

DENTAL CARIES AND DIET.

To the Editor of THE LANCET.

SIR,—It seems to me that undue hopes with regard to a certain method of preventing dental caries may be aroused by your leading article of last week. About a decade ago, the theory of a vitamin-C deficiency as the cause of caries was taken up with extraordinary enthusiasm in America, but under the fire of criticism during the last two or three years this theory has, I think, been largely disposed of, and probably accounts for the change over to the vitamin-D theory. In this country we have been rather regaled with investigations and inferences, firstly on fat-soluble A and later on vitamin D, in attempts to explain the prevalence of caries. But here again neither of these theories has stood up to the fire of criticism. Further, they have been tried in a very practical way, but what do we find? According to the *Dental Surgeon* (April 5th, 1930) "we are already meeting with cases where children are devastated with caries, who have been dieted with cod-liver oil, and where the fond and anxious parents have pinned their faith to this food—in vain."

That a diabetic diet—in which sugar and carbohydrates generally are reduced to a minimum—will correspondingly reduce the incidence of caries, is recognised by those of us who hold that sugar lodging about the crevices and retention areas of the teeth is the principal cause of dental caries, and the accuracy of this view no doubt accounts for the good results recorded among children on the diabetic diet, especially when this contains meat, fruit, and vegetables. Apart from statistical investigations and the clinical evidence which shows this theory to be true, recent investigation [1] by Prof. R. W. Bunting and his collaborators shows that when the amount of sugar is reduced in children's diet *B. acidophilus* tends to disappear and dental caries correspondingly becomes arrested.—I am, Sir, yours faithfully,

Harley-street, W., Nov. 23rd, 1930. J. SIM WALLACE.

DIAGNOSIS OF PULMONARY TUBERCLE.

To the Editor of THE LANCET.

SIR,—In his Mitchell lecture, reported in your issue of Nov. 22nd, Dr. Burrell gives a welcome survey of the difficulties inherent in the diagnosis and management of early cases of pulmonary tuberculosis, and affords a very present help and encouragement to some of us who, labouring in the wide spaces of general medicine, may sometimes find it hard to maintain the confidence in our opinions which is essential to a successful issue when grappling with this particular problem. In this connexion it may be of interest to mention two or three points which have been impressed upon me during the years of practice.

Whereas, for the most part, the clinical picture presented by persons who have suffered from hæmoptysis, other than that of tuberculous origin, is sufficiently characteristic to render mistaken diagnosis unlikely, in my experience one of the most tricky and misleading conditions is the early morning hæmoptysis resulting from gingivitis, which is not seldom diagnosed as being due to early tuberculosis, more frequently perhaps than is hæmoptysis from any other non-tuberculous lesion. It seems that the very simplicity of the condition is the reason that it is overlooked; the consequences of a mistake so glaring are correspondingly grave.

An interesting point made by Dr. Burrell is that physical signs are very occasionally the first indication of disease. It is difficult to account for the absence of all symptoms in these cases which are of importance because unexpected and because, as Dr. Burrell says, it is becoming the custom in some schools to belittle the value of physical signs. Some time ago, during examination for life insurance of a young man whom I had known for some years, I came upon a crop of persistent moist sounds over a patch of lung internal to the angle of the left scapula. There were no other signs of disease, and the patient looked and felt perfectly well. A postponement of the insurance was followed by a X ray examination which confirmed the suspected diagnosis of tuberculosis, and subsequently cough developed with tubercle bacilli in the sputum. Eventually he made a good recovery and is now an apparently healthy married man.—I am, Sir, yours faithfully,

Torquay, Nov. 22nd, 1930. A. E. CARVER.

[1] Dental Cosmos, October, 1928, and April, 1930.

THE CHARTERHOUSE RHEUMATISM CLINIC

To the Editor of THE LANCET.

SIR,—All those working on the rheumatic problem will be interested in the figures published in your last issue (p. 1151), but I suggest that they would be still more interested if the Charterhouse Clinic would produce similar figures which could be analysed by ordinary statistical methods. In the first table, the types treated are too diversified to enable any definite conclusions to be made from the figures given, as they include types of rheumatic disease not generally attributed to infection. If a scientific evaluation of vaccine therapy is to be effected, I suggest that the inquiry should be confined to one main group, such as rheumatoid (infective) arthritis, and that the results should be presented in such a manner that they can be examined by the usual mathematical methods. An inquiry such as this has been proceeding at the Devonshire Hospital for several years, on the following lines:

Type of case = Infective arthritis (all cases of subacute rheumatism, fibrositis, osteo-arthritis, &c., rigidly excluded); Total number of cases = 330; Total replying to postcard = 273; Period covered by inquiry = January, 1928 to January 1930; Vaccine = *Streptococcus viridans*; No difference in figures considered significant unless greater than the possible variation due to chance.

In view of the tendency of this type of case to spontaneous exacerbation and remission it is necessary in attempting to estimate the value of treatment, to compare the number of cases improved after treatment with those improving before treatment was commenced, and to obtain similar data in a control series of adequate size. As far as a comparison is possible, the total improved among the patients under treatment at the Charterhouse Clinic is much the same as on discharge here, 92 per cent. as against 91·35 per cent. The total *subsequently* improved in vaccine treated cases was 61 per cent. as compared with 77·4 per cent. at the Charterhouse Clinic. This difference is probably accounted for by the fact that all our cases were of infective arthritis. On admission 48 per cent. of our vaccine-treated patients stated that they were improving. These two figures (48 per cent. and 61 per cent.) may be regarded as strictly comparable, as both (the condition on admission and the reply to the postcard) represent the subjective condition as given by the patient. The difference between these two figures (61% − 48% = 13%) is barely significant when the standard of deviation is considered. When the figure of 13 per cent. is compared with a similar figure in a control series of 550 non-vaccine treated cases, the difference (3 per cent.) is obviously of no significance. I am, Sir, yours faithfully,

PHYLLIS M. CONGDON, M.D., Dipl. Bact.,
Bacteriologist, Devonshire Hospital, Buxton.
Nov. 25th, 1930.

OBITUARY

DAME MARY SCHARLIEB, D.B.E., M.D., M.S. Lond.,

CONSULTING GYNÆCOLOGIST, ROYAL FREE HOSPITAL.

THE critical state of Dame Mary Scharlieb's health has been known to the public as well as to her immediate circle for a long time; her death occurred on Nov. 21st at the residence of her son, Dr. H. J. Shirley.

Mary Dalcomb Scharlieb was born in London in 1845, the daughter of William Candler Bird. The mother survived by only a few days the birth of the infant, who was temporarily confided to the care of her grandmother; for her father, who had just become a member of a firm in Manchester, departed to make a new home there. Mary Bird soon, however, joined him and was educated at boarding schools in Manchester, New Brighton, and finally in London. Her father made a second marriage, and she acted as governess to three small half-sisters, the children of a kind and wise step-mother, until, when she was 20 years old, she met her husband, William Mason Scharlieb, a student at the Bar, who was intending to practise in Madras. Marriage followed quickly on engagement, and in 1865 the young couple left for India.

DAME MARY SCHARLIEB.

[*Photograph by Elliott and Fry.*

Dame Mary in her short and interesting "Reminiscences," describes how, after the birth of her second child, she received the impetus which determined her career. Her husband was editing the *Madras Jurist*, and she assisted him in collating material and writing précis for this journal. In 1871 there came to her notice in his way Fayrer's work on medical jurisprudence, and the description of the suffering of Hindu and Mahometan women in childbirth, under the *purdah* rules, so affected her that she determined to assist as a nurse at the lying-in hospital at Madras. One year of such work sufficed to assure her that a knowledge of midwifery alone would not make her a competent adviser to native women, and she determined to return to England and take advantage of the movement for the medical qualification of women which had been led by Sophia Jex Blake and Elizabeth Garrett Anderson. The commercial bad fortune of her father indirectly led to the achievement of her wishes. Mr. Bird's firm fell on evil days, and William Scharlieb offered hospitality to his wife's father and step-mother and their children. As a consequence, under new family arrangements, Mary Scharlieb became free to pursue her medical studies in Madras. In 1878 she obtained the diploma of L.M.S. and M. from the Madras Medical College, and she was supported by the Madras Government in her intention to graduate in medicine in England. Accordingly she returned to London and joined the London School of Medicine for Women, which had shortly before been affiliated to the Royal Free Hospital. At this period she received much practical help from Prof. (now Sir) Edward Sharpey-Schafer, then assistant professor of physiology at University College; while Florence Nightingale, Sir Henry Acland, and Elizabeth Garrett Anderson gave her warm encouragement.

This was a stirring period in the medical education of women. In 1875 the London School had started with a three years' curriculum—the statutory period of that date, but the medical schools attached to the teaching hospitals refused to admit the women students, and the examining boards would not accept their certificates of attendance. The question whether the Medical Acts were intended to confine the practice of medicine to men having been settled in favour of the broader view, Russell Gurney, M.P. for Southampton and Recorder of London, succeeded in the House of Commons with a short permissive Bill giving medical examining boards the power to admit women to their examinations. In the same year the treasurer of the new school, James Stansfeld, M.P. for Halifax, entered into negotiations with the Royal Free Hospital, to which institution no male students were attached, and the authorities of the hospital were found willing to admit women students to the wards on a guarantee against possible loss of subscriptions. Between 1877 and 1882, the period covered by the original agreement with the Hospital, the School made progress, and while the number of students was still small their quality was high; among Mary Scharlieb's co-students, when she entered were, for example, Helen Prideaux, Annie McCall, and Julia Cock, who later filled the post of Dean. At the intermediate examination in medicine at the University of London, in 1881, the Gold Medal and exhibition in anatomy were awarded to Helen Prideaux, whose tragic death occurred three years later, while Mary Scharlieb in the same year took first-class honours in materia medica and forensic chemistry, following up these successes by obtaining, in the examination for the M.B. degree, the gold medal and exhibition in obstetric medicine, with honours in medicine and forensic medicine.

After a short period of post-graduate work in Vienna, where she attended special courses at the Frauenklinik and under the famous Politzer, Mary Scharlieb returned to London, preparatory to following her original intention of practising in Madras as an obstetric physician. It was now that Queen Victoria received her at the instance of Sir Henry Acland, and commanded from her a plain account of the sufferings caused to Caste and Gosha women by their inability to avail themselves of the services of male doctors. The Queen was deeply affected by the shocking narrative, which later was repeated, at special request, to the Prince of Wales (King Edward VII.). The Royal interest thus manifested in her plans was of great value to Mary Scharlieb when she arrived again in India in 1883. She was immediately made lecturer on her subjects in the Madras Medical College, was appointed to an examinership in the College, and

later became medical superintendent of the Royal Victoria Caste and Gosha Hospital, whose foundation was due to her energies, assisted by Lady Grant-Duff and Surg.-General Furnell. For the next four years she conducted a large medical practice in Madras single-handed, for there was no other woman practitioner available, and no male doctor would have been permitted to assist in her ministrations to Indian women. But by 1887 excessive work had so told on her health that she was obliged to recognise the sense of the medical advice which ordered her to England without delay.

She returned to London and has put it on record that she was received with helpful kindness by many of the leading members of the medical profession aware of her intention of carrying on gynæcological and consulting practice. She was appointed joint lecturer on medical jurisprudence in the School of Medicine for Women, and, although she failed to obtain a place on the staff at Great Ormond-street, she was appointed physician to out-patients at the New Hospital for Women, which, thanks to the energies of Mrs. Garrett Anderson, had developed from a small dispensary into the hospital in the Euston-road which is now known as the Elizabeth Garrett Anderson Hospital. Here she worked for many years with notable success. But she had the resolution also to continue academic study, for she proceeded to the M.D. degree in 1888, while in 1896 she was the first woman to obtain the M.S.

Her Indian work now stood her in good stead, and her operating theatre in the Euston-road hospital was often visited by colleagues who came to see her methods. To their judgment, to some extent, must have been due the next step in her career, for in 1892 Dame Mary was appointed gynæcologist to the Royal Free Hospital, where a vacancy had just occurred. This was the first time that a woman had held any position on the visiting staff of a general hospital, and not only men viewed the appointment with some apprehension. But she disarmed criticism alike by her surgery and her attitude towards all with whom she worked, colleagues in the wards and the nursing staff. In 1902, at the age of 57, she was appointed gynæcological surgeon. In 1905, at the age limit of 60, her services were so valuable to the hospital that she was reappointed for another year. She was again reappointed in October, 1906, and again in 1907. She resigned her post at the end of 1908, when she was appointed consulting gynæcological surgeon to the hospital. When her resignation was accepted, the board gave a full and long expression of their indebtedness for her valuable surgical work and for the services she had rendered so long to the hospital. They mentioned that her relationship with the board and her medical colleagues was the most harmonious possible during her term of office and they expressed their very great regret that she could no longer hold the post. She never lost touch, however, with the hospital, and as President of the London School of Medicine for Women she interested herself very much in the welfare of the staff and the students, keeping up her connexion with those who were entering the medical profession. Perhaps even stronger than her enthusiasm for surgery was that for the due training of medical women.

Her professional work outside the hospital was notable. Before women were admitted to the medical societies she had been an active member of the Association of Registered Medical Women which met at the hospital in Euston-road, and there she frequently spoke and read scientific papers. Later, when t Obstetric Society opened its doors to women, she too part from the first in debates, and with the formati of the Royal Society of Medicine she became a pr minent member of the Obstetric Section. From t start until quite recently she carried on a lar consulting practice, performing major operations, a enjoying the confidence of a large number of sufferi women. She was a member of the Royal Commissi on Venereal Diseases which finally reported in 191 and in the following year she was made C.B.E. 1926 she was made D.B.E.

In the social and philanthropic sides of life Dar Mary Scharlieb had many interests. She was honora treasurer of the Royal Medical Fund Guild, and the Women's League of Service for Motherhood, s was a justice of the peace, doing admirable work the Children's Court, and she supported numero philanthropic institutions. But always she found tir to lead a full private life and many friends have hap memories of her hospitality. Her husband died 1901. She had three children, two sons and daughter, the younger son, Dr. Herbert John Shirle C.M.G., and the daughter entering the medical pr fession. Her elder son, a soldier, who had also earn the distinction of C.M.G., predeceased her abo a year ago, while her daughter, Dr. El Scharlieb, died in 1926. Until the death of h daughter Dame Mary and she had lived in the sa house in Harley-street in which the mother co menced practice; when the house was pulled do she went to live with her son, who by changing h name avoided confusion with his mother. Dr. Shirl during the later years of his mother's practice help her in every way, especially as an anæsthetist in h operation cases and in the after-care of patients. It from Dr. Shirley we learn of the peaceful end, Dame Mary's mind remained perfectly clear and s was free from all acute pain.

Mary Scharlieb leaves behind her fragrant memori An exponent of high endeavour, every action w dictated by the desire to benefit humanity, followi the Christian example as she viewed it. Pity suffering supplied the first impulse; intention give to suffering her best aid encouraged her, as middle-aged woman and the mother of a fami during the tedium of class-rooms; and a who hearted devotion to her science lay behind t strenuous and successful routine of her daily li She took holiday rests in quiet places, using t leisure now and again to publish a book in popu style on subjects related to medicine or on soc affairs with which her experience fitted her to de She wrote a modest autobiography under the title "Reminiscences." And she is said to have confess to two social ambitions—to be presented at Co and possess a diamond necklace; when both wish were attained she confessed "Now I have my t vanities."

Dame Mary Scharlieb was a good citizen, a devot wife and mother, a great surgeon, and a very hum person.

HERBERT SNOW, M.D. Lond.

Dr. Snow, who died on Nov. 20th at St. Leonar on-Sea, was nearly 84 years of age. He was on surgical staff of the Cancer Hospital, Brompt from 1876 to 1905, and published a compendi treatise on cancers and the cancer process. He at that time a keen critic of the theories then vogue, and set out in our own columns sound reas

why cancer could hardly be due to a micro-organism, and why the so-called parasitic protozoa were nothing more than a kind of endogenous cell-formation. Later in his career he promulgated theories of cancer which in their turn were criticised, and the latter part of his life was largely given up to an attempt to demonstrate the futility of physiological research as a means of promoting medical science. From 1908 on he was consulting surgeon to the National Anti-vivisection Hospital at Battersea.

EWAN RICHARDS FRAZER, M.B. Oxf.

Dr. E. R. Frazer, whose death on Nov. 15th was announced in our columns last week, was the son of Mr. John Frazer, of Sydney, and was born in 1867. He entered Balliol College, Oxford, in 1887, intending to study history, but was soon attracted to the study of pathology by his friendship with James Ritchie who was then collaborating with Burdon Sanderson. After taking his B.A. in 1892 he went on to the London Hospital for his clinical work, graduating in medicine at Oxford in 1898, and obtaining the Conjoint diploma in the same year. He visited Copenhagen, studying there under Salomonsen at a time when Dreyer was acting as his first assistant. Frazer was then regarded as a coming man in pathology, and papers on pathological subjects continued to appear from his pen, although his systematic study was interrupted by his return to Australia on the death of his brother. In another way, however, pathology at Oxford owes him a lasting debt, for it was due to his generosity while still an undergraduate that the school of pathology was provided with a department of its own. The donation was made under the following circumstances.

"Seated one night by my fireside," writes Prof. Arthur Thomson, "for he often dropped in to have a smoke and chat with me, Frazer surprised me by saying that he was anxious to do something to help the medical school. I confess, at first, I did not quite see the drift of his remark, until he explained that he had a considerable balance lying to his credit at the bank, and that he did not know what to do with it. At that time the University was sorely in need of money, for in spite of the efforts of Sanderson and Ritchie, the University was without a pathological laboratory, wherein provision could be made for the appropriate teaching of the subject, I set the facts before him, with the result that he handed me a cheque for £5000. Knowing full well the difficulties that had arisen in regard to the establishment of other departments in the early medical school, I suggested the propriety of his putting the money in trust with me and his lawyer, until such time as the University was willing to comply with such conditions as we thought necessary to impose before the University obtained possession of his gift. This was a new departure, but we had previously learned that opposition had been raised to building grants on the grounds that the departments concerned were not in any way to be associated with experiments on animals. In this way the trustees of the benefaction were in a position to arrange terms with the authorities of the University.

"It was not altogether an agreeable business for a comparatively young man, as I was then, to lay down conditions to a Vice-Chancellor, but it was all finally settled in an amicable manner, and Frazer's £5000, supplemented by a contribution from the University, enabled the school to be provided in 1901 with a department, in which the late Prof. Ritchie so successfully carried out the teaching of pathology until the time that we were deprived of his services by his appointment to the chair of bacteriology in Edinburgh. Since then, and until the University profited by the benefaction of the Sir William Dunn trustees in 1926, Prof. Dreyer, appointed Ritchie's successor, continued to occupy the original building, which is now utilised as the up-to-date department of the professor of pharmacology, Dr. J. A. Gunn.

"The incident," Prof. Thomson concludes, "is in my experience unique, and well worthy of being recorded to the memory of the big-hearted undergraduate who recognised in such substantial measure the debt he owed to his alma mater."

Recently Dr. Frazer had lived in comparative retirement at East Grinstead and in London, but not long ago he founded a scholarship to be held at Balliol College by a student of natural science from Winchester College, in memory of his eldest son who was killed while ski-ing in Switzerland. Dr. Frazer was in his sixty-fourth year.

JOHN HAMMOND TEACHER, M.D., F.R.F.P.S. Glasg.

WE have to record that Prof. Teacher died on Nov. 21st at Glasgow, where his life was spent from boyhood. A son of the late William Teacher of that city, he was born in 1869, and was educated at the Academy and at the University. Graduating in arts in 1888 and in medicine four years later, he first held resident posts at the Western Infirmary and then was appointed assistant curator of the museum, left to Glasgow University by William Hunter. In 1899 he published a catalogue of the anatomical and pathological specimens in this collection, and in the same year was appointed assistant to the professor of physiology. In 1903 he received the Bellahouston medal on graduating as M.D., and published his important thesis on chorion epithelioma in the *Journal of Obstetrics of Gynæcology of the British Empire*. He now became assistant to the professor of pathology, and this led on to the lectureship in pathological histology (1908). He joined the staff of St. Mungo's College as professor of pathology in 1909, and succeeded to the St. Mungo (Notman) chair of pathology in the University in 1911. During this period he was also working for the hospitals, first at the Western Infirmary and the Royal Hospital for Sick Children, and from 1909 onwards as pathologist to the Royal Infirmary. His research and interests were varied. Although not an anatomist in the stricter meaning of the term, his name was well known to all anatomists and embryologists. He followed with sustained enthusiasm the drawn-out search for material which could throw light on the conditions and problems of early development; in this he made full use of the opportunities afforded by his work as a pathologist, and was able to call on skilled experts for help in deciphering the results of his labours. In this way he came to be associated with Prof. T. H. Bryce and Dr. Munro Kerr in the establishment of present-day views about the early stages of the embedded ovum as well as on the nature of the embedding itself. Perhaps the most widely known of the products of this collaboration is the famous Bryce-Teacher ovum, which at one time stood as the youngest known stage in human development. This ovum was first brought to public notice some 22 years ago. Its position as the earliest ovum is no longer unchallenged, but the ovum retains and will always

have a great value in descriptive as well as historical embryology. The careful calculations on well-founded data which went with it, moreover, have altered the views generally held about the ages to be assigned to human embryos. For these contributions to our knowledge—and for others less widely known—Teacher's name will be held in remembrance for many a year among anatomists and embryologists.

As a pathologist he saw the whole development of the Glasgow school since Coats first convinced the University that his subject needed and deserved academic recognition. For many years he was one of the solid elements of British pathology, whom everyone respected as a sound and reliable worker and to whom everyone referred for information on his special topics. As long ago as 1894, in collaboration with Coats, he published an account of a monster, and his subsequent interests were largely obstetrical and gynæcological. Apart from his studies on the ovum he will be chiefly remembered for his work on chorion-epithelioma and the symmetrical cortical necrosis of the kidneys associated with pregnancy. More recently he pointed out in his interesting and practical way that post-operative vomiting may leave active gastric juice in the lower end of the œsophagus, leading to ante-mortem digestion and sometimes hæmatemesis. "He had a lot of nervous idealism in his composition," writes a colleague. "It ran out perhaps more in his passion for yachts than in the post-mortem room, but he really cared about pathology and set himself a standard of thoroughness which was wholly admirable."

Prof. Teacher married in 1904 Rachel, daughter of the late J. M. Hutcheson, of Greenock.

GEORGE HUGH KIDD MACALISTER, M.D. Camb., M.R.C.P. Lond., D.P.H.

Dr. Hugh Macalister, who died in London o Nov. 2nd after a long illness, had been Princip of King Edward VII. College of Medicine at Singapo since 1918. Born at Dublin in 1879 he w the younger son of Dr. Alexander Macalister, lat professor of anatomy in the University of Cambridg and the brother of Edith, the wife of Sir Donal MacAlister. Hugh was educated at Charterhouse an St. John's College, Cambridge, continuing his medic course at Guy's Hospital and graduating in 190 He then held resident house appointments at Guy before he became assistant bacteriologist there, an later at the Lister Institute. He went to India i 1914 as pathologist to the Imperial Laborator at Muktesar, and four years later migrated t Singapore, where he was professor of clinical medicin and lecturer on therapeutics, as well as principal o the school. Although well qualified in many branche of medicine and pathology, it is as an administrato that his name will be chiefly remembered, for h planned and raised funds for the new buildings of th Singapore College, which, in his hands, became highly efficient school. He was an active membe of the Pathological Society of Great Britain, and hi papers cover such various ground as dysenter carriers, paroxysmal hæmoglobinuria, and immunisa tion in tuberculosis. For the last two years of th war he was on service in Mesopotamia with the ran of Captain I.M.S. His particular recreation wa climbing. Principal Hugh Macalister marrie Margaret, daughter of William Moir, and leaves hi widow with two young daughters.

MEDICAL NEWS

University of Cambridge.

On. Nov. 14th the degrees of M.B. & B.Chir. were conferred on John Vaughan-Bradley.

Society of Apothecaries of London.

At recent examinations the following candidates were successful :—

Surgery.—E. Jacomb, Charing Cross Hosp. ; L. A. Riddell, Univ. of New Zealand ; and W. K. Schnarr, Guy's Hosp.

Medicine.—R. P. Davies, London Hosp. ; L. A. Riddell, Univ. of New Zealand ; and W. K. Schnarr, Guy's Hosp.

Forensic Medicine, Hygiene and Insanity.—G. W. Hinchliff, St. Mary's Hosp. ; H. G. Hind, St. Bart.'s Hosp. ; W. A. Naidu, London Hosp. ; W. W. Parry, Guy's Hosp. ; L. A. Riddell, Univ. of New Zealand ; L. Sachs, St. Mary's Hosp. ; and S. H. Thaler, Guy's Hosp.

Midwifery.—S. J. Bellgard, St. Mary's Hosp. ; G. I. Benjamin, Univ. of Madras ; C. L. Ferguson, London Hosp. ; W. G. Kingston, Middlesex Hosp. ; E. H. W. Lyle, King's College Hosp. ; M. S. Mules, Royal Free Hosp. ; and H. C. Pain, Univ. of St. Andrews and Middlesex Hosp.

The following candidates, having completed the Final Examination, are granted the diploma of the Society entitling them upon registration (under the Medical Acts) to practise medicine, surgery and midwifery : R. P. Davies and E. H. W. Lyle.

University of Liége.

On Nov. 15th the degree of M.D. *Honoris causa* was conferred on Dr. G. H. F. Nuttall, F.R.S., Quick Professor of Biology in the University of Cambridge.

Australian and New Zealand Medical Association.

The winter dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, Dec. 12th, at 7.45 P.M. for 8.0 P.M. Mr. T. P. Dunhill will preside, and the High Commissioner for Australia will be the official guest of the association. All medical visitors from Australia and New Zealand, whether members of the association or not, are invited to be present. The address of the secretaries is 26, Queen Anne-street, London, W. 1.

Royal Dental Hospital Dinner.

The annual dinner of the Royal Dental Hospital was hel at the Trocadero Restaurant, London, on Nov. 22nd with Dr. Harvey Hilliard in the chair. About 180 member of the staff, past and present students and visitors wer present. The toast of the Hospital and Dental Schoo was proposed by the Chairman, who emphasised th importance of systemic disease to dental work. He ha become more and more impressed by the extent to whic disease of the mouth had its origin in general disease o dysfunction—especially of the digestive organs—and h pleaded for closer coöperation between doctor and dentist for the benefit of both and of their patient. Even a simpl caries indicated that the patient was not in perfect health and to fill a carious tooth was to treat a symptom and ignore a cause. Their hospital, he said, was the mother o dental hospitals and schools and the home of denta anæsthesia. Referring to the new in-patient department he said that more beds were needed, and that he would lik to see the institution of research beds with a researc physician and of travelling scholarships. Sir William Goschen, responding to the toast, commented on the grea strides made of recent years in hospital administration and nursing. He expressed his profound belief in the voluntary system, and said that one thing that did not change was th love for one's hospital. Mr. Harry Stobie, Dean of the Denta School, also in reply, referred to recent resignations and appointments, and to the resuscitation of the Students Society. The health of the visitors was proposed by Mr. A. T Pitts, who attempted to classify them on a zoological basis but feared that those whom he classed among the edentata might resent the allusion to their personal deficiency Sir John Rose Bradford replied on behalf of the guests, and the health of the Chairman was proposed by Dr. A. W Oxford. After Dr. Hilliard's reply the evening concluded with a muscial programme.

A Hospital Lottery.

It is stated that the Government of New South Wales intends to introduce a lottery for the benefit of the hospitals of the State. It is believed that £500,000 per annum can thus be raised.

AT a Court meeting this month Dr. Hugh Stannus Stannus was sworn as Master of the Worshipful Company of Founders.

A New Roman Catholic Hospital.

The Institute of Trained Nurses of Our Lady of Compassion has acquired 18 houses in Barkham-terrace, Lambeth-road, opposite Bethlem Hospital, upon the site of which it is proposed to erect at a cost of £100,000 a hospital of 100 beds and a training school for nurses.

Cheyne Hospital for Children.

A small private ward is now available at this hospital in Cheyne-walk, Chelsea, S.W., for the reception of children of 3 to 13 years of age requiring a prolonged course of treatment, whose parents, whilst unable to afford a full nursing home fee, are able to pay more than the small maintenance charge for patients in the general wards of the hospital. Private patients eligible for admission include those suffering from osteomyelitis, anterior poliomyelitis, dislocated hip, surgical tuberculosis, certain forms of infantile paralysis, rickets, rheumatoid arthritis, chorea, and heart disease. Children will be admitted by arrangement with, and for treatment by, a member of the hospital medical staff; practitioners not acquainted with members of the staff should apply to the secretary. A weekly charge of from £3 3*s*. to £5 5*s*. will be made by the hospital.

Radon for Midland Hospitals.

The National Radium Commission has lent half a gramme of radium to the University of Birmingham for the production of radon at a rent of £120 a year and £30 a year for insurance. The Faculty of Medicine of the University will establish a rota for radon supplies, beginning in January next, embracing all hospitals recognised by the Faculty as teaching institutions connected with the University; general or special hospitals in the area, not recognised as teaching hospitals, but of a similar type and working on similar lines; and municipal and poor-law institutions. It is suggested that for the first year the charge for the supply of radon should be 1*s*. 6*d*. per millicurie.

Hospital for Sick Children.

The Prince of Wales, as President, has launched an appeal for £500,000 for the reconstruction and re-equipment of the Hospital for Sick Children, Great Ormond-street, London. The new building is to occupy the present site, it having been found impossible to acquire another equally suitable in the neighbourhood. The work will be carried out in instalments as means permit, but there will be no interruption of the hospital's activities. The wards will all face south and have balconies. The main block for patients will be set back 250 ft. from Great Ormond-street, and between it and an out-patients' block there will be a garden. The existing chapel and out-patients' hall will remain, and the staff will be housed in a separate building fronting Guilford-street.

Leeds Maternity Hospital.

Mrs. Stanley Baldwin last week opened extensions of this institution which have cost over £64,000, of which £8000 is still required. Beginning as a nursing home, the hospital is now one of the chief maternity hospitals in the country. In a speech following the opening ceremony, Dr. Arthur Hawkyard, Lord Mayor of Leeds, recalled that Dr. William Hey, who was Mayor of Leeds in 1787 and again in 1802, was in the habit of publicly dissecting the bodies of criminals from Wakefield gaol. Three courses of these anatomical lectures produced £112, which was given to the Leeds Infirmary.

Donations and Bequests.

Mr. Joseph Squiers, of Birmingham, left, among other bequests, £100 each to the Queen's Hospital, Birmingham, the Birmingham Skin and Lock Hospital, the Birmingham Ear and Throat Hospital, the Birmingham Eye Hospital, the General Hospital, Birmingham, the Birmingham General Dispensary, and the Royal Institute for the Blind, Edgbaston. After the death of his wife, the Birmingham Hospital for Nervous Diseases, the Royal Cripples Hospital, Birmingham, and the Children's Hospital, Birmingham, will each receive £1250 to endow an Ellen Squiers Cot or Bed. —Among other bequests, Miss Jessie Jane Donald, of Glasgow, left £1000 each to the Western Infirmary, Glasgow, the Royal Infirmary, Glasgow, the Victoria Infirmary, Glasgow, and the Scottish National Institute for Blinded Soldiers and Sailors; £500 each to the Glasgow Royal Cancer Hospital, the Royal Hospital for Sick Children, Glasgow, the Princess Louise Scottish Home for Limbless Sailors and Soldiers, and the Glasgow Ear, Nose, and Throat Hospital.—Mrs. Matilda King, of Clifton, Bristol, £1000 to Handel Cossham Memorial Hospital, Kingswood, Bristol; £1000 to the Bristol Royal Hospital for Sick Children and Women, St. Michael's-hill, Bristol, and £300 to the Bristol Medical Missionary Society.

Irish Medical Schools and Graduates Association.

The general meeting of this association will be held at the Piccadilly Hotel on Thursday next, Dec. 4th, at 7.15 P.M. On the same evening at 7.45 the association will dine at the hotel, with Dr. W. P. Kennedy in the chair and Sir Frederick O'Connor as official guest. Tickets may be had from Mr. James Carver, St. George-in-the-East Hospital, London, E.1.

King Edward VII. Hospital for Officers.

This hospital, which was founded by Miss Agnes Keyser ("Sister Agnes") at 17, Grosvenor-crescent, London, during the South African War in 1899, has now been incorporated by Royal Charter. At the first meeting of the council last week a message was received from the King expressing his wishes for the continued welfare of the hospital under the new conditions.

Deptford Babies' Hospital.

An appeal is being made on behalf of this hospital of 20 beds maintained by voluntary workers in a densely populated and poor district. It is wholly inadequate to the need, and money is urgently required to enable the work to continue, but a larger modern building is demanded by the situation. The hospital is housed in two ancient cottages one of which is said to have been occupied by Nelson. The kitchen is entered by the door of a ship's cabin, and the street door is secured by a portion of a chain from the *Victory*.

Visits of Hospital Governors.

The governors of Cameron Hospital, West Hartlepool, have adopted a plan for regularising their visits to the wards. A rota is to be prepared of those governors who wish to act as official visitors, divided into 12 groups. Governors so appointed will be entitled to visit the hospital officially once during their month, and they will be accompanied on their tour by the matron, the secretary, or the sister-in-charge.

Wingfield Orthopædic Hospital.

Sir William Morris has given £47,000 for the rebuilding of this hospital, at Headington, near Oxford. The existing buildings consist of war-time huts, and it had been proposed to erect four open-air wards of 20 beds each, at a cost of £12,000. The hospital and its clinics are conducted by the Berks, Bucks, and Oxon Association for the cure of cripples, and there are 130 beds and three private wards. The last annual report stated that the number of patients had increased by 20 per cent. and the new patients attending the clinic by over 30 per cent. Sir William Morris's gifts to hospitals now exceed £364,000.

Medical Fees in Accident Cases.

The County Councils Association has had a letter from the Minister of Health about proposals made to him by the British Medical Association for the payment of doctors' fees for attendance on road accidents. The secretary has reported that the following resolution was passed by the association in 1925: "That, where necessary, members of police forces should be authorised to summon medical assistance in cases of emergency, such as accidents or sudden illness in the street, and that the doctor's fee for such attendance (but not for any subsequent attendance) should, if not obtainable by him from the person attended, be paid by the police authority, and be a charge upon the police fund." The County Councils Association has now decided that, while appreciating the circumstances to which its attention has been drawn by the Minister of Health, it is strongly opposed to the assumption by county councils of any responsibility, otherwise than as is stated in the foregoing resolution, for payments to doctors in respect of services rendered by them in connexion with road accidents.

Proposed English Hospital Sweepstakes.

Sir Gordon Campbell, chairman of St. Bartholomew's Hospital Appeal Committee, and a number of his friends have prepared for consideration a concrete, though tentative, plan to benefit hospitals. "We suggest," they say, "that there should be one or more sweepstakes each year for the benefit of the hospitals; that 33 per cent. of the gross takings should be available for the hospitals concerned, and that expenses should be limited to clerical staff and the printing and distribution of particulars and tickets. On the question of conducting a sweepstake on these lines outside this country, in the event of the necessary legislation here being unobtainable, our views are that, considering the large number of our countrymen who reside on or are visiting the Continent, there should be no insurmountable difficulty in such a sweepstake being organised and conducted on the Continent by a responsible committee resident over there." In order to test opinion, Sir Gordon and his friends are considering the advisability of issuing a questionaire on the subject to the supporters of St. Bartholomew's.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

HOME-GROWN FRUIT.

IN the House of Commons on Wednesday, Nov. 19th, Viscount ELMLEY moved :—

"That this House deplores the present condition of the fruit-growing industry and the heavy losses incurred this year by growers, and calls upon His Majesty's Government to put into effect schemes which, without penalising the consuming public, will secure to the grower an economic return for his crop."

He said that a great deal of jam was being sold to-day as fresh jam which was made from preserved fruit, and that meant that people were not getting what they contracted to buy. He and many others were very uneasy about the public eating jam which had been preserved in sulphur dioxide for two years. Those who had seen this pulped fruit preserved with sulphur dioxide would agree with him that it was most unpleasant looking stuff. He realised that it was not possible for the Minister of Agriculture to send a commission to every country to inquire as to the conditions under which this stuff was made, but he asked the Minister to state the amount of sulphur dioxide which was allowed in fruit.

Mr. DE ROTHSCHILD, in seconding the motion, said it was certainly not right that children—and it was children who consumed most of the jam—should be fed on jam made from stale pulp preserved with SO_2. He urged the Minister of Agriculture to confer with the Minister of Health on this matter in the interests of public health.

JAM MADE FROM PRESERVED PULP.

Dr. ADDISON (Minister of Agriculture) said that he remembered that as a child he was given brimstone and treacle. After all this pulp preserved with SO_2 was brimstone and treacle in a diluted form. The Government could not insist upon the marking of this stuff because quite inadvertently they were prevented by the Merchandise Marks Act from insisting upon a description of such an imported article which underwent a material change after it reached this country. This fruit pulp preserved in SO_2 was boiled down and made into jam, and it was held that thus it had undergone an important change and was sold as home-made jam. It was home-made jam, but not made from British fruit. He hoped it might be possible in a friendly way to negotiate some verbal alterations of the Act which would enable the Government to deal with this difficulty. He thought that the way to help the fruit industry was on the lines of improved organisation, especially in the direction of the small producer.

Dr. FORGAN said he was glad that the Minister of Agriculture hoped to put an end to the use of foreign preserved pulp for jam-making in this country. It was contradictory that they should prevent children from drinking cream containing SO_2 while they allowed them to eat jam containing the same preservative. It might be well to hold an inquiry into the matter as well as into the sale of graded jam in this country. It might be that the dioxide in the pulp was changed in some way when the fruit was made into jam, but chemical analyses of numerous samples of jam had revealed the interesting fact that the chemical composition of the sugar in the jam was so altered that the food value was reduced almost to vanishing-point, and some jams made with pulp were actually harmful to the digestive organs. Either the Ministry of Agriculture or the Ministry of Health ought to investigate this subject. That debate had been concerned primarily with the interests of the producers, but he thought that the consumers' interests ought also to be considered. There had been a slogan for some time past of "Eat more fruit," but speaking as a medical man he found that the doctor had not been kept away from th homes of the people, because not nearly enough fru yet was consumed, and one reason for that was tha although the producers were not getting a fair pric for their produce the prices to the consumer wer in many cases, unnecessarily high. If they coul help the producer and at the same time reduce th price of fruit they would be contributing ver materially to an improvement in the health of th people, particularly in regard to dentition, which wa a disgrace to this country.

The motion was agreed to without a division.

MOTORISTS AND THIRD-PARTY INSURANCE.

On Tuesday, Nov. 25th, Mr. REMER asked leave t introduce the Road Traffic Act 1930 (Amendment Bill, a measure to compel insurance companies t issue third-party insurance certificates to moto drivers having no convictions for careless, reckless or dangerous driving against them. He said tha insurance companies were very largely refusing t issue insurance certificates to people who had pre viously insured with them, the reason given bein that those persons had a bad insurance record The effect of this was to give insurance companie the power to say whether a person should drive car or not, as the Road Traffic Act made it a condi tion of the issue of a driving licence that the applican should be insured against third-party risks. H contended that the decision as to whether a perso was to drive a car or not should not be left to th discretion of insurance companies.

Mr. C. WILLIAMS opposed the Bill. He said tha although it would compel insurance companies t issue certificates for third-party insurance to certai people, it did not state the terms on which they shoul do so. This would mean that those insurances woul only be granted at prohibitive rates, which was contradiction of the terms of the Bill.

Leave was granted to introduce the Bill by 24 votes to 100, and the Bill was brought in and read first time.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 19TH.

Maternal Mortality.

Mr. RHYS DAVIES asked the Minister of Health whether the rate of maternal mortality differed as between women insured under the national health insurance scheme and those outside its scope; and, if so, what was the difference in percentages.—Mr. GREENWOOD replied: I regret that no statistics are available on this subject.

Suicides in Great Britain.

Mr. KINLEY asked the Home Secretary the numbers of suicides in Great Britain for each of the past ten years to the latest date.—Mr. SHORT replied: The numbers of suicides in England and Wales have been as follows:—1920, 3373; 1921, 3715; 1922, 3844; 1923, 3919; 1924, 3679; 1925, 4054; 1926, 4408; 1927, 4863; 1928, 4846; 1929 (provisional figures), 4907. I have no information as to Scotland, and any question should be addressed to the Secretary of State for Scotland.

THURSDAY, NOV. 20TH.

White Lead Poisoning.

Mr. GRAHAM WHITE asked the Home Secretary the number of cases of lead poisoning notified, and the number of deaths since the imposition of the new regulations dealing with the use of white lead.—Mr. SHORT replied: The regulations under the Lead Paint Act came into force on Oct. 1st, 1927. During 1928, 87 cases were reported, including 20 deaths; during 1929, there were 75 cases, including 10 deaths; and during the nine months ending Sept. 30th last, there were 43 cases, including 9 deaths.

Mr. WHITE: Could the hon. gentleman say whether he is satisfied that these regulations are sufficient to meet the needs of the case?

Mr. SHORT: I may say that they are constantly under review, having regard to the facts on cases that are brought to our notice.

Erskine House Hospital.

Mr. NEIL MACLEAN asked the Minister of Pensions the aximum accommodation at Erskine House and the number f limbless ex-Service men treated there during 1925, 1926, 927, 1928, and 1929 respectively.—Mr. ROBERTS replied: he present number of beds at Erskine House available or Ministry of Pensions cases is 63. During the years 925–1929 limbless and other surgical cases were treated t the Ministry of Pensions surgical centre at Bellahouston, hich will shortly be transferred, under the present surgical ontrol, to Erskine House.

Manufacture and Sale of Absinthe.

Major OWEN asked the Home Secretary whether he was repared to introduce legislation forbidding the manuacture, sale, and use of absinthe in this country.—Mr. HORT (Under-Secretary, Home Office) replied: No, Sir.

Major OWEN: Is the hon. gentleman aware that legislaon has been passed already in France, Belgium, Switzerand and Germany forbidding the sale and manufacture f this drink, and is this country going to lag behind these ther countries in this matter?

Mr. SHORT: I am aware of the facts stated by my hon. riend, but so far as I am aware there is no ground on which o take the action he suggests.

Supply of Milk to School Children.

Dr. HASTINGS asked the President of the Board of Educaon if he could give the relative proportions in which ertified, grade A (T.T.), pasteurised, and ordinary undesigated milk were supplied to children in elementary schools.—ir CHARLES TREVELYAN replied: I regret that I am unable o give this information. In approving arrangements for ie provision of milk by local education authorities the oard call the attention of the authority to the importance f their satisfying themselves as to the purity and quality f the milk, but they have no information as to the relative roportions in which the different grades of milk are supplied.

Tuberculosis on Tyneside.

Mr. EDE asked the Minister of Health if he had received report from his representative who recently investigated ie prevalence of tuberculosis in the county borough of outh Shields; if so, what action he proposed taking; and he would consider at an early date calling a conference the authorities for dealing with tuberculosis on the yneside, with a view to securing the inauguration of a entralised and comprehensive scheme at the earliest ossible moment.—Mr. GREENWOOD replied: The answer o the first part of the question is in the affirmative. I have ready communicated with the town council and have ade certain suggestions for increasing the hospital proision available for the treatment of this disease in South ields. As regards the last part of the question, if the cal authorities concerned consider that a conference ould be desirable, I shall be glad to do anything in my ower to facilitate it.

Mr. EDE: May I take it that the right hon. gentleman ould be willing to call such a conference if requested and range for one of his officers to attend?

Mr. GREENWOOD: Oh, most certainly.

Drug Advertisements in Medical Papers.

Mr. FREEMAN asked the Minister of Health whether he ould consider the desirability of amending the Medical ct of 1886 with a view to controlling advertisements of rugs in medical papers.—Mr. GREENWOOD replied: I am ot aware that there is any ground for proposing to extend e control which I understand is already exercised over dvertisements of this character by the proprietors of the edical journals concerned.

Treatment in Mental Hospitals.

Mr. KINLEY asked the Minister of Health whether the eatment of patients in public mental hospitals was laid own by the Board of Control or whether the medical ficer in charge had full or partial liberty in matters of eatment.—Mr. GREENWOOD replied: The answer to the st question is in the negative and to the second that the ethod of treatment of patients is within the discretion the medical officer of an institution.

Dissection of Paupers' Bodies.

Mr. DAY asked the Minister of Health whether his attenon had been drawn to the fact that the public assistance mmittees of several counties had decided that in future odies of friendless paupers were to be available for disction at medical schools; whether any regulations existed which a friendless pauper, who was dying in a hospital, as notified of the fact that his body would be handed er for the purpose of dissection unless he protested; and were any arrangements made by the authorities to satisfy themselves that when the dissected body was buried the correct remains of the body were properly interred.—Mr. GREENWOOD replied: The answer to the first and third parts of the question is in the affirmative. As regards the second part, any inmate of an institution may express a desire that his body shall be interred without anatomical examination, and Section 7 of the Anatomy Act, 1832, provides that such a wish shall be respected.

Closing of Bellahouston Pensions Hospital.

Mr. NEIL MACLEAN asked the Minister of Pensions (1) when the Ministry of Pensions first received intimation from the Glasgow Corporation to remove from Bellahouston where suitable alternative accommodation was looked for; and why such alternative accommodation was refused and Erskine House selected; and (2) whether he was aware of the dissatisfaction among ex-Service men in Glasgow at the publication of his decision to have ex-Service patients requiring indoor treatment removed to Erskine House from January, 1931; and whether he would reconsider his decision.—Mr. ROBERTS replied: Repeated intimations have been received from the Glasgow Corporation that the site of the hospital is required for civic purposes, and, though they generously extended the department's occupation on several occasions, I have, as already stated, now decided that existing requirements do not justify further occupation of the site beyond January next. After careful consideration I have come to the conclusion that Erskine House is entirely suitable as alternative accommodation for the treatment of ex-Service men in the West of Scotland, and I am unaware of any ground for altering this decision.

TUESDAY, NOV. 25TH.

Education of Mentally Defective Children.

Major CHURCH asked the President of the Board of Education if local education authorities compiled complete records of the careers of children after leaving school who had been segregated for education purposes in schools for the mentally defective.—Mr. MORGAN JONES (Parliamentary Secretary to the Board of Education) replied: The Board urge all local education authorities which provide schools for mentally defective children to compile records of the after-careers of children who have left, so far as they are able, and nearly all authorities do so; but they are not in a position to ensure that these records shall be complete. An analysis of the records for seven areas will be found in paragraph 88 of the Report of the Board's Chief Medical Officer for 1925.

Imports of Cream.

Brigadier-General CLIFTON BROWN asked the President of the Board of Trade how much unsterilised cream had been imported into this country since Jan. 1st, 1930, and from what countries it came.—Mr. W. GRAHAM replied: During the ten months ended Oct. 31st, 1930, the total quantity of cream imported into this country amounted to 116,733 cwts. of which nearly 99 per cent. was consigned from the Irish Free State, Denmark, the Netherlands, and Switzerland. I am unable to state what proportion of this cream was unsterilised.

Experiments with Poison Gas.

Mr. SINKINSON asked the Secretary for War how many soldiers were being experimented upon by being gassed at Porton; and what was the extra allowance in pay given for having gas tried upon them.—Mr. T. SHAW replied: No soldiers are "gassed" at Porton in the ordinary sense of the word. But volunteers, averaging some six a week, undergo tests with the object of proving the efficacy of preventive and curative treatment for skin burns and of confirming the adequacy of the protection afforded by respirators. The volunteers receive extra leave, and in certain cases pay of 1*s.* or 6*d.* for each test.

Mr. TURNER asked the Secretary for War whether any of the experiments undertaken under the direction of the Chemical Warfare Committee had reference to the offensive possibilities of poisonous or asphyxiating gases in warfare.—Mr. T. SHAW replied: The research and experiments now being conducted have solely defensive measures in view.

Physical Condition of Army Recruits.

Major GLYN asked the Secretary for War if he would furnish a return showing the general average physical condition of recruits at all the Army depôts, Royal Engineers, Royal Artillery, cavalry, foot guards, infantry of the line, tank corps, and departmental services on joining the Service, with any notes the Director-General of Army Medical Services might care to make as to the usual disabilities and defects that were most noticeable, and indicating the physical development of these men after three and six months' training at the depôts and with their units.—

Mr. T. SHAW replied: The standard of physical fitness required of recruits for enlistment in the Army is laid down in the instructions for the physical examination of recruits. For the recruiting year 1928–29, which is the latest period for which information is yet available, the main disabilities leading to the discharge of recruits were: disease of the middle ear; defects of lower extremities; disease of heart; and defective vision. An investigation which is at present being carried out in the London area appears to show that the general physical standard of the recruits actually accepted in that area is, if anything, higher than that of recruits accepted before the war. I am further informed by the Army medical authorities that the physical development of recruits during their first six months o training is most satisfactory, and that weight is put on at the depôts to the average of 6¼ lb. Figures are not available as to the weight increase after three months' training, but both the general physical development and increase in weight are steadily and evenly progressive.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Dec. 2nd.—8 P.M., PATHOLOGY. Laboratory Meeting at the Imperial Cancer Research Fund Laboratories, Queen-square, W.C. 8.30 P.M., ORTHOPÆDICS. Paper: Dr. L. Böhler (Vienna): The Treatment of Fractures of the Upper Extremity. A discussion will follow.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Discussion: The Relation of the Teaching of the History of Medicine and that of Clinical Teaching. Opener: Dr. W. R. Bett: Clio by the Bedside. MEDICINE. Members of this Section are specially invited to attend and take part in the discussion. 8.30 P.M., SURGERY. Discussion: Surgery in Diabetes. Openers: Prof. G. E. Gask, Dr. George Graham, and Dr. Lawrence. Followed by Mr. C. A. R. Nitch and others. MEDICINE. Members of this Section are specially invited to attend and take part in the discussion.

THURSDAY.—8 P.M., TROPICAL DISEASES. Presidential Address by Dr. J. Gordon Thomson.

FRIDAY.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.) Discussion on Intracranial Complications of Otitic Origin: Neurological and Pathological Investigation. Papers by Dr. George Riddoch and Dr. A. B. Rosher. Discussion on the Committee's Report on Hearing Tests. 5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Demonstrations of cases illustrating Plastic Repair after Operations on the Upper Jaw by Mr. Musgrave Woodman, and illustrating Repair after Operations on the Pharynx by Mr. Lionel Colledge. A short demonstration will be given by Dr. Arthur F. Hurst of A Method of Treatment in Asthma and Hay-fever. 8.30 P.M., ANÆSTHETICS. Cinematographic demonstration by Prof. F. T. G. Hobday on his anæsthetic apparatus and the administration of anæsthetics in veterinary surgery. Cases will be shown.

BRITISH INSTITUTE OF RADIOLOGY AND RONTGEN SOCIETY,

WEDNESDAY, Dec. 3rd.—2.30 P.M. (at the Central Hall, Westminster), official opening of Exhibition by Sir Humphry Rolleston. 3.30 P.M., Presidential address by Mr. C. E. S. Phillips, F.Inst.P.

THURSDAY.—10.30 A.M. to 12.30 P.M., Technical papers. 5 P.M., Prof. G. P. Thomson, F.R.S.: Some Recent Experiments on Cathode Rays (Mackenzie Davidson lecture).

FRIDAY.—10.30 A.M., Medical papers. Dr. H. A. Harris: The Growth of Bone as illustrated by Radiography. Dr. Donald Hunter: Changes in the Bones in Hyperparathyroidism and Hyperthyroidism. 4.30 P.M., Dr. A. E. Barclay: The Danger of Specialisation (Silvanus Thompson lecture).

SOCIETY OF CHEMICAL INDUSTRY (London Section).

MONDAY, Dec. 1st.—8 P.M. (in the Rooms of the Chemical Society, Burlington House, W.), Mr. J. H. Coste, D.Sc.: Analytical Chemistry, its Past History and Future Development.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY, Dec. 1st.—8 P.M., Prof. C. R. Darling, F.I.C.: Modern Domestic Scientific Appliances, Heating of Rooms, and Hot Water Supply.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, Dec. 5th.—8 P.M. (at the De Vere Hotel, Kensington High-street), Dinner, followed by discussion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn-fields, W.C.

MONDAY, Dec. 1st, and following WEDNESDAY and FRIDAY.—4 P.M., Mr. F. W. Twort: Diseases of Bacteria. (Free lectures.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Dec. 1st to SATURDAY, Dec. 6th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon. at 4 P.M., free lecture by Mr. W. H. Ogilvie on Recent Advances in Surgery. Tues., at 10, Bedford-square, W.C. Special M.R.C.P. Lecture at 8.30 P.M., by Dr. Knyvett Gordon: The Diagnos of Diseases of the Blood-forming Organs. Followe by a laboratory demonstration.—KING'S COLLEG HOSPITAL, Denmark-hill, S.E. Thur., at 2 P.M., fre demonstration by Dr. Terence East (Cardiol).— WESTERN OPHTHALMIC HOSPITAL, Marylebone-roa N.W. Thur., at 2 P.M., free demonstration in Ou patient Department by Mr. T. C. Summers.—WE END HOSPITAL FOR NERVOUS DISEASES, 73, Welbec street, W. Special course in neurology at 5 P.M. dail —HOSPITAL FOR DISEASES OF THE SKIN, Blackfriar road, S.E. Afternoon course.—THE INFANTS HOSPITA Vincent-square, S.W. Special afternoon course.

NORTH-EAST LONDON POST-GRADUATE COLLEG Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 1st.—2.30 to 5 P.M.: Medical, Surgical, a Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nos and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and E Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M Medical, Surgical, Throat, and Ear Clinics. Operatio

FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2. to 5 P.M.: Medical, Surgical, and Children's Diseas Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEG Hammersmith, W.

MONDAY, Dec. 1st.—10 A.M. to 1 P.M., Surgical War Genito-Urinary Operations, Skin Department. 2 P.M Operations, Surgical Wards, Medical, Surgical, E and Gynæcological Out-patients.

TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clini Demonstration (Surgical), Dental Department. 2 P.M Operations, Medical, Surgical, and Throat Out-patien

WEDNESDAY.—10 A.M. to 1 P.M., Medical and Surgi Wards, Children's Medical Out-patients. 2 P.M Gynæcological and General Operations, Medic Surgical, and Eye Out-patients.

THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patien Demonstration of Fractures. 2 P.M., Operatio Medical, Surgical, and Genito-Urinary Out-patien

FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Depa ment, Dental Department, Clinical Demonstrati (Medical). 2 P.M., Operations, Medical, Surgical, a Throat Out-patients.

SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacter Therapy Department, Medical Wards, Childre Medical and Surgical Out-patients.

KING'S COLLEGE, Strand, W.C.

THURSDAY, Dec. 4th.—5 P.M., Mr. W. Robson, D.Sc Protein Metabolism. (Last lecture.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOO Denmark-hill, S.E.

THURSDAY, Dec. 4th.—9 P.M., Dr. Sydney Thomso Treatment of Syphilis.

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Dec. 1st.—4.15 P.M., Dr. Charles Singer: Fou Centenary of the Invention of the Word "Syphili 5 P.M., Mr. L. E. Bayliss, Ph.D.: Respiratory Functio of the Blood. (Last lecture.)

CITY OF LONDON MATERNITY HOSPITAL, City-road, E

THURSDAY, Dec. 4th.—5 P.M., Dr. McKim McCullag Treatment of Obstructed Labour.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATIO St. James's Hospital, Ouseley-road, Balham, S.W.

THURSDAY, Dec. 4th.—4 P.M., Dr. Worster-Drough Recent Advances in Diagnosis and Treatment of Nervous System.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Dec. 3rd.—4.30 P.M., Mr. C. H. Mills: So Interesting Urological Cases.

CENTRAL LONDON THROAT, NOSE, AND EAR HO PITAL, Gray's Inn-road, W.C.

FRIDAY, Dec. 5th.—4 P.M., Mr. N. Asherson: Chro Otorrhœa.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

MONDAY, Dec. 1st.—2.15 P.M., Mr. Frederick Roqu The First Stage of Labour.

TUESDAY.—2.15 P.M., Mr. C. S. Lane Roberts: Some Mi Gynæcological Ailments. 3.15 P.M., Mr. A. M. Zamo Indications for Operative Interference in Ear Disea

WEDNESDAY.—2.15 P.M., Dr. Bernard E. Schlesing Demonstration of Cases in Children's Ward. 3.15 P. Dr. H. C. Semon: Modern Views on the Nature Treatment of Eczema.

THURSDAY.—2.15 P.M., Mr. E. Wolff: Cataract. 3.15 P. Dr. P. O. Ellison: The Cerebro-Spinal Fluid.

FRIDAY.—2.15 P.M., Mr. W. B. Gabriel: Obstruct Jaundice. 3.15 P.M., Dr. C. Gouldesbrough: Radiol of Gall-bladder and Urinary Tract.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospi 49, Leicester-square, W.C.

TUESDAY, Dec. 2nd.—5 P.M., Dr. A. C. Roxburgh: Cutane Syphilis (1).

THURSDAY.—5 P.M., Dr. A. C. Roxburgh: Cutane Syphilis (2).

ST. JOHN'S HOSPITAL, Morden Hill, Lewisham.

MONDAY, Dec. 1st.—4.30 P.M., Dr. John Gibbens: Jo Diseases in Children.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russ square, W.C.

WEDNESDAY, Dec. 3rd.—4 P.M., Prof. D. B. Blacklo Prevention of Disorders in Tropical Countries.

THURSDAY.—4 P.M., Mr. F. J. McCann: Medical Argume Against Contraception.

NSTITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, Dec. 3rd.—3.30 P.M., Dr. V. Zachary Cope: Causation and Prevention of Appendicitis.

ANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Dec. 2nd.—4.15 P.M., Mr. H. H. Rayner: Diagnostic Value of Recent Advances in X Ray Examination of the Urinary and Biliary Tract.
FRIDAY.—4.15 P.M., Dr. W. Blair: Mental Exhaustion.

NIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.
FRIDAY, Dec. 5th.—3.30 P.M. (at the Royal Infirmary), Dr. J. H. Cobb: Syphilitic Infections of the Nose and Throat.

NCOATS HOSPITAL, Manchester.
THURSDAY, Dec. 4th.—11 A.M., Dr. N. Kletz: Clinical Demonstration. 4.15 P.M., Dr. A. Renshaw: Systematic Pathological Investigation of a Case of Rheumatoid Arthritis.

Appointments

OYD, J. LINDSAY, M.D. Glasg., F.R.C.P. Edin., has been appointed Assistant Honorary Physician to the North Staffordshire Royal Infirmary.
RY, R. M., L.R.C.P. Lond., M.R.C.S., Assistant Director of the Research Laboratory, Queen Charlotte's Maternity Hospital.
OLDBERG, I., M.B., Ch.B. Edin., House Surgeon, Hampstead General and North-West London Hospital.
ACKAY, I. C., M.B., Ch.B. Edin., D.P.H., Deputy Medical Officer of Health for Cheshire.
CREDIE, P. A., M.B., Ch. B. Edin., Medical Referee under the Workmen's Compensation Act for Wigtown County.
ILLIAMS, G., M.B., Ch.B. Liverp., Medical Officer, Trawsfynydd, Merioneth.
chmond, Whitworth, and Hardwicke Hospitals: ABRAHAMSON, L., M.D., B.Ch. Dub., and O'CONNOR, J., M.D., B.Ch.N.U.I., Honorary Physicians.

Vacancies

For further information refer to the advertisement columns.

bert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.
lfast, Joint Nursing and Midwives' Council for Northern Ireland. Examiners of Midwives.
rkenhead General Hospital.—Sen. H.S. £150.
rmingham Ear and Throat Hospital, Edmund-street.—Res. H.S. £150.
adford Royal Eye and Ear Hospital.—Jun. H.S. £150.
ry St. Edmunds, West Suffolk General Hospital.—Jun. Res. M.O. £150.
rdiff Royal Infirmary.—Two Hon. Surgeons.
ntral London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. to Out-patient Dept.
elsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.
eshire Joint Sanatorium, Market Drayton, Salop.—H.P. £250.
ester Royal Infirmary.—H.S. £150.
ownpatrick, N. Ireland, Down Mental Hospital.—Jun. Asst. M.O. £300.
eadnought Hosp. Greenwich.—H.P. and H.S. At rate of £110.
ublin, Dr. Steeven's Hospital.—Res. Surg. Also Res. Asst. Surg.
unedin, New Zealand, Otago University.—Prof. of Midwifery and Gynæcology. £2000.
unfermline, West Fife Infectious Diseases Joint Hospital.—Asst. M.O. £400.
eter, Royal Devon and Exeter Hospital, Pathological Department.—Pathologist. £500.
asgow Corporation, P.H. Dept.—Deputy M.O. for Mental Services. £1000.
ampshire County Council.—Asst. County M.O. £600.
ampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.P. and H.S. Each at rate of £100.
rrogate Infirmary.—Res. Sen. and Jun. H.S.'s. At rate of £150 and £125 respectively. Also Res. H.P. At rate of £150.
uddersfield Royal Infirmary.—H.S. At rate of £150.
ull Royal Infirmary, Sutton Branch.—H.P. At rate of £160.
eds, Killingbeck Tuberculosis Sanatorium.—Asst. Res. M.O. £250.
incolnshire (Kesteven) C.C.—Asst. County M.O.H. £500.
verpool, Royal Children's Hospital.—Res. H.P. At rate of £100.
verpool, Royal Southern Hospital.—Hon. Dental Surgeon.
verpool University.—Jun. Lecturer in Dept. of Pathology, £300.
ndon Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150.
ndon Temperance Hospital, Hampstead-road, N.W.—Cas. O. Also H.P. At rate of £120 and £100 respectively.
westoft, St. Luke's Hospital.—Jun. Asst. M.O. £500.
anchester, Ancoats Hospital.—H.S. for General Surgery, &c. At rate of £100. Also Med. and Surg. Registrars. Each £100. Also Orthopædic Reg. (part-time). £25.
anchester Babies' Hospital, Burnage-lane, Levenshulme.—Sen. Res. M.O. At rate of £125.
anchester City, Abergele Sanatorium.—Med. Supt. £900.
anchester Royal Eye Hospital.—Jun. H.S. £120.
ildmay Mission Hospital, Austin-street, Bethnal Green, E.—Asst. Cas. O. At rate of £125.
iller General Hospital, Greenwich-road, S.E.—H.P. and H.S. Each at rate of £125. Also Out-patient Officer. At rate of £150.
onmouthshire County Council.—Two Asst. M.O.'s. Each £500.
ational Hospital, Queen-square.—H.P. £150.
ewcastle-upon-Tyne, Hospital for Sick Children.—Res. H.P. Also Jun. H.S. Each at rate of £100.
New Zealand, Hawkes Bay Hospital, Napier.—Pathologist. £750.
Nottingham City Infirmary, Hucknall-road.—Two M.O.'s. Each £350.
Oswestry, Shropshire Orthopædic Hospital.—Asst. Orthopædic Surgeon. £450.
Plymouth Central Hospital.—H.S. At rate of £120.
Pontefract General Infirmary.—H.S. £150.
Preston, Sharoe Green Hospital, Fulwood.—Jun. Res. M.O. At rate of £104.
Prince of Wales's General Hospital, N.—Hon. Clin. Assts. to Various Departments.
Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O., H.S.'s, H.P.'s, &c. At rate of £200, £150, and £120 respectively. Also Anæsthetist to Dental Dept. £25.
Queen's Hospital for Children, Hackney-road, E.—H.P. and H.S. Each at rate of £100.
Royal National Orthopædic Hospital, Great Portland-street, W.—Hon. Asst. Surg.
St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. £125.
St. Mary's Hospital, W.—Surgical Registrar. £200.
St. Thomas's Hospital.—Chief Asst. in Physico-therapy Dept. £250.
Salford Royal Hospital.—Res. Surg. O. At rate of £200. Also H.P., Two H.S.'s, and Cas. H.S. Each at rate of £125.
Salisbury, General Infirmary.—H.S. £150.
Sheffield, City of.—Asst. Tuber. Officer. £500.
Sheffield Royal Hospital.—Ophth. H.S. Also Res. Anæsthetist. Each at rate of £80.
Sheffield Royal Infirmary.—Ophth. H.S. £80–£100. Also Clin. Asst. to Ear, Nose, and Throat Dept. £300.
Somerset County Council, Sandhill Park, Bishop's Lydeard, nr. Taunton.—Med. Supt. £850.
South Shields, Harton Hospital.—Two H.S.'s. Each £120.
Staffordshire County Council.—Asst. Bact. and Path. £600.
Tilbury Hospital, Essex.—H.S. At rate of £150.
West London Hospital, Hammersmith-road, W.—Non-Res. Cas. O. £250. Also H.P., H.S., and Aural and Ophth. H.S. Each at rate of £100.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Surg. Reg.
Wigan Royal Infirmary.—Res. M. and Surg. O. and Reg. £250.
Windsor, King Edward VII. Hospital.—H.S. At rate of £100.
Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. At rate of £100. Also Part-time Pathologist. £300.
Worcester General Infirmary.—Jun. Res. M.O. £120.
Wrexham and East Denbighshire War Memorial Hospital.—Hon. Surgeon to Ear, Nose, and Throat Dept.
York Dispensary.—Res. M.O. £150.

Births, Marriages, and Deaths

BIRTHS.

INKSTER.—On Nov. 15th, at Middlesbrough, to Olive Mary, the wife of John Inkster, M.D. Aberd., M.R.C.P. Lond.—a daughter.
JOULES.—On Nov. 21st, at South Hill Nursing Home, Mary, the wife of Horace Joules, M.D., M.R.C.P., The Hospital, Selly Oak, Birmingham, of a son.

MARRIAGES.

COPEMAN—BOURNE.—On Nov. 15th, at St. Albans Cathedral, William Sydney Charles Copeman, M.B., M.R.C.P., to Helen, youngest daughter of the late W. W. Bourne, Esq., and Mrs. Bourne, of Garston Manor, Herts.

DEATHS.

LOCKET.—On Nov. 18th, at his residence, New Holme, Bratton, Wilts., Thomas Wood Locket, M.D., M.R.C.S.
MAINGAY.—On Nov. 17th, at a nursing home, Henry Bertram Maingay, F.R.C.S., of Queen-street, Scarborough, aged 63.
SCHARLIEB.—On Nov. 21st, at the residence of her son, Dr. Herbert Shirley, York-terrace, Regent's Park, Mary Scharlieb, Dame of the British Empire, M.D., M.S. Lond., LL.D. Edin., J.P., aged 85.
SNOW.—On Nov. 20th, suddenly, at St. Leonards-on-Sea, Herbert Snow, M.D., late Senior Surgeon and Consultant, Cancer Hospital, London.
STEEL.—On Nov. 21st, at Abergavenny, Colonel William Dyne Steel, D.L., J.P., V.D., M.D., aged 75.
WALLACE.—On Nov. 18th, at Woking, Robert William Lessel Wallace, M.C., M.D. Edin., aged 49.
WILSON.—On Nov. 21st, in a London nursing home, Dr. Ralph W. Wilson, M.D., of The Moorings, Kew Gardens.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE annual congress and exhibition of the British Institute of Radiology, incorporated with the Rontgen Society, will be opened by Sir Humphry Rolleston at the Central Hall, Westminster, at 2.30 P.M. next Wednesday, Dec. 3rd. Mr. C. E. S. Phillips will give the presidential address. The Mackenzie Davidson lecture will be delivered by Prof. G. P. Thomson, F.R.S., on Thursday at 5 P.M., and the Silvanus Thomson lecture by Dr. A. E. Barclay on Friday at 4.30. Further details will be found in our Medical Diary.

NOTES, COMMENTS, AND ABSTRACTS

WAKENING OF HOSPITAL PATIENTS.

THE Central Public Health Committee of the London County Council has inquired into a suggestion that hospital patients should not be awakened before 6 o'clock in the morning. Under the late boards of guardians the times of wakening patients at the 28 general hospitals varied considerably. At ten of them patients were wakened at or before 5 A.M., at nine the times of wakening began at 5 A.M. or later, and proceeded by degrees, extending in one case to as late as 7.30 A.M., and at the remaining nine the time for wakening did not begin until 6 A.M. These arrangements have so far been continued. The Committee says :—

"It will be appreciated from the answers to the questionaire issued by the Central Bureau of Hospital Information [1] that informed opinion is by no means unanimous on the principle of allowing patients to sleep until 7 A.M., apart from purely staff considerations. Nor can local conditions be ignored. In London, the cases of Middlesex and Guy's Hospitals are illustrative. At the former, situated in the West Central district of London, external traffic conditions with resultant noise continue until late at night and recommence at a relatively late hour in the morning. At Guy's Hospital, in close proximity to Borough Market, traffic begins at a very early hour and ceases relatively early at night. The wards at Guy's Hospital close down at 8 P.M. and reopen at 6 A.M. At the Warneford, Leamington and South Warwickshire General Hospital the routine awakening of patients at 5 A.M. was altered for a month or two as an experiment, and breakfasts were served at 7 A.M. and after a time at 8 A.M. Objections were taken to the new arrangements on the ground that too long a period elapsed since the previous meal of the evening before, and that it was not possible in the shorter time available to clean and prepare the wards. With the agreement of the majority of nurses and patients the former routine was reverted to.

"Evidence shows, therefore, that there can be no hard-and-fast rule. . . . Generally speaking, there must be a time for a particularly important duty to which other considerations must conform. This may be taken as the time at which the medical staff commence their rounds, after the patients have breakfasted and have been prepared for the day, in order to finish the rounds before the patients' dinner-time. This time is usually in the neighbourhood of 10 A.M. The time necessary to prepare patients and wards for the medical officers' visits is governed by the staff available. In turn, the times of awakening regulate the times for closing down, in order to ensure that the patients have sufficient rest. In the case of the Council's hospitals the patients are only disturbed in exceptional cases after 8 P.M., and nine to ten hours are therefore available for rest."

The Committee proposes that, as far as practicable, no patient should be awakened, except in special circumstances, before 6 A.M., and that those hospitals which are below this standard should be raised up to the standard as and when staff are available.

INFRA-RED IRRADIATION.

RADIANT heat is frequently prescribed and has proved valuable in the treatment of various and dissimilar clinical conditions. It is more than probable that these conditions are not all benefited to the maximum extent by exposure to identical regions of the spectrum. Differences in the permeability of the tissues to various rays and differences in the depth of the lesions—to mention two obvious factors only—make it essential to obtain apparatus whose emission is known and whose output can be controlled.

The Beaumont-Mason infra-red generator made by Messrs. Mason (Electro-Medical), Ltd., 96, Wigmore-street, London, W., consists of five graphite elements mounted so as to allow of flexibility and ready adjustment in any position. Each element carries its own electrical component and is provided with a pilot lamp. Graphite was chosen for the elements because it is said to have the highest emission factor of all the materials tested for that purpose. Infra-red rays are produced by heating the elements to th desired extent and the patient's skin can be cool during treatment by the use of an electric fan. Th absence of an admixture of visible rays and th absence of loss of radiation by filtering throu coloured glass are notable points in this apparatus.

In the Sollux lamp (British Hanovia Quartz Lam Co., Ltd., Slough), use is made of both visible an infra-red radiation. A 1000 watt bulb is mounted front of a large parabolic reflector and by mea of focal adjustment it is possible to secure diverger parallel, or convergent rays. The feature of intere is the presence of an adjustable resistance whi controls the intensity of the luminous heat-sourc The apparatus is supplied with a small conic reflector used as an extension to the large reflect for irradiation of small areas and with a filter-fra and glass filters which can be used when it is desir to exclude one part of the spectrum from the ra emitted by this lamp.

LYMPHATIC LEUKÆMIA.

To the Editor of THE LANCET.

SIR,—I should be grateful if any of your reade could put me in touch with a case of lymphat leukæmia for a special investigation. A case that h been under observation for a long time and y showed symptoms would be of particular value.

I am, Sir, yours faithfully,

Guy's Hospital, S.E., Nov. 24th, 1930. E. P. POULTON.

ULCERS OF THE SKIN.

To the Editor of THE LANCET.

SIR,—I read with great interest in your issue August 16th (p. 382) your quotation on this subj from *Archiv für Schiffs- und Tropen-Hygie* Leishmaniasis of the skin is a common disease Arabia. It is usually named after the city or count where the disease exists. In Transjordania a Palestine it is called Jericho ulcer, white Alep button, Bagdad ulcer, Nile ulcer, and Yeman ul are a few of its very numerous names. While readi your quotation the idea of looking for leishma parasites occurred to me and I rejoiced to find confirmed by Dr. Ziemann.

The Prince Abd-alla of Transjordania develop eight ulcers on his arm a month after his return his country from a visit last year to his brother t King of Iraq. Microscopic examination of scrapin from the edges of two of the eight ulcers show leishmania parasites. All kinds of local treatme and intramuscular injections of Fouadin (an orga antimony compound) were without avail, until finally succeeded in procuring an apparatus th condenses, in the form of solid snow, carbon diox gas under pressure from iron cylinders. Cauterisi the ulcer with solid carbon dioxide reduces its nat to a simple skin ulcer that can be cured within two three weeks, with a simple antiseptic dressing. T ointment I used was 2 per cent. pellidol (di-acet amino-azotoluol).

The eight ulcers of the Prince and one ulcer on t hand (dorsal aspect) of a servant of his were cured this simple and safe way. There is no doubt th solid carbon dioxide is the specific of leishmania of the skin. There are two theories to explain t mode of action. The first is that the ulcer bein disease of hot countries, it is reasonable to treat with excessive cold, and the temperature of so carbon dioxide is 79° C. below zero. The second the attributes the cure to the destruction of the lei mania parasites by the leucocytosis that follows t application of the solid gas. It is very probable th both freezing and leucocytosis coöperate in curi

I am, Sir, yours faithfully,

Amman, Transjordania. D. F. TU-TUNJI

ADDRESSES AND ORIGINAL ARTICLES

MATERIA MEDICA AND THE PRACTICE OF MEDICINE.*

By David Campbell, *M.C.*, M.A., B.Sc., M.D. Glasg.,
REGIUS PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE UNIVERSITY OF ABERDEEN.

A distinguished teacher of mine once startled his class by asking what a tiger does when it is suffering from septicæmia. The students regarded the conundrum as merely amusing, yet the answer is of considerable importance. For the tiger, so far as we know, would differ from most human beings in having no preconceived notions as to how to deal with the situation. It would not be troubled with current theories of physiology and pathology, nor would it be handicapped by the fads and fashions of the therapeutic notions of the time. It would probably simply go and rest near a pool of water, where it could assuage its feverish thirst. It would, in fact, adhere strictly to the method of Hippocrates, relying entirely on the power indicated in the ending canon of that great physician, *νούσων φύσεις ἰητροί*, or, as it is better known in its translated and paraphrased form, "vis medicatrix naturæ."

Possibly, however, our tiger in its agony might try the effect of some plant or grass, for the apparently instinctive practice of taking drugs is believed to exist among the lower animals. It is a fascinating subject for the speculative mind to ponder how this instinct arose, and how, as primitive man struggled upwards, a belief in the power of drugs to remedy disease originated. Perhaps in the trying out of plants as foods some knowledge of their effects was obtained—purgative, emetic, carminative—and thus certain of them were set aside for medicinal purposes. It is clear at any rate that faith in drugs, especially vegetable drugs, has been deep-seated and widespread amongst all peoples from earliest times. It is as strong in modern civilisation as it was amongst primitive men.

The subject of materia medica or medicinal agents, therefore, is one of the most ancient of medical studies. It had its foundation in observation and pure empiricism, and in the beginning was really the simple practice of medicine. At first its practical application was in the hands of women, probably because women would naturally look after the sick, but later it was transferred to specialised medicine-men. Then with the development of reason came new difficulties. One great characteristic of *Homo sapiens* is that he tends instinctively to fill up the blanks in his knowledge by having recourse to conjecture and hypothesis. In one way that is a healthy instinct, for where complete and accurate knowledge is unattainable, a working hypothesis, though wrong, may be better than no hypothesis at all. But it has obvious disadvantages. Primitive man regarded everything he could not explain as being the work of some god, and when he came to reason about the cause of disease it was perhaps not unnatural that he should explain convulsions, delirium, and disease generally, on the hypothesis that the patient was possessed of a devil or evil spirit. And so, to the simples and drugs of materia medica was added exorcism or the casting out of devils. The knowledge of disease and of the means of dealing with it gradually passed into the hands of the priest-physician. Materia medica, magic, and mystery became almost synonymous terms.

Observation, Reason, and Experience.

In medicine it took an unusually long time for men to realise that to call normal phenomena natural, and abnormal divine, introduces an absurd dualism; but gradually the conception of the divine origin of disease was discarded, to be replaced by something perhaps even worse—philosophical theory. For the Greek philosophers in their desire to frame a comprehensive theory of disease shut their eyes to fact, and with their *ὑποθέσεις* or postulates sought to explain medical phenomena by *a priori* assumptions. They wove theories of pathology without putting them to the test of experience, and on these erroneous theories was perforce based irrational treatment

In the midst of this confusion of mystery and speculation there arose the "Father of Medicine," Hippocrates, of whom it was said by Celsus that he achieved the feat of separating medicine from philosophy. He saw that actual experience and study of disease were of far greater importance than philosophical interpretations based solely on figments of the imagination, and though his conceptions of pathology were often quite erroneous, he taught the necessity of understanding the natural history of disease. He observed that though drugs were usually given to patients, recovery sometimes took place where no drug had been administered; and he deduced from that the existence of a natural spontaneous healing power within the living organism, that power of which I have already spoken—vis medicatrix naturæ. The first great step in scientific medicine, therefore, not only involved a doubt about the curative results of empirical methods of treatment, but also made an appeal to the natural laws of living organisms to effect the cure of the sick. It would be well if every student and practitioner of medicine kept that thought in the forefront of his mind. It would save him from drawing many erroneous conclusions from his therapeutic observations. Hippocrates relied more on simple regimen than on materia medica. But this expectant treatment which observes and foresees the course of disease without attempting to act directly on its progress is not wholly satisfying. It is an excellent maxim that therapeutic measures should not in any way disturb the beneficent tendencies of nature—primum non nocitur—but what is to be done if the tendencies are malign? Surely, said some of the successors of Hippocrates, it is justifiable in those circumstances to combat and to try to dominate Nature. And so the reaction to mere expectancy in therapeutics began. The fashionable Roman physician, Asclepiades, coined his unfair aphorism that Hippocratic treatment was merely a "meditation upon death." The empiricists once more held sway. But the great achievement of Hippocratic medicine stood. It substituted observation, experience, and reasoning in place of theory and magic.

Then followed the tragedy of the dark ages, and for a thousand years, while Western Europe was plunged in intellectual darkness, no great change or advance in the treatment of disease took place. In the sixteenth century, when medical research and learning once more became part of the general

* The substance of an Inaugural Address delivered in the University of Aberdeen on Oct. 20th.

activities of civilised nations, the naturalist-physicians began to take stock of their materia medica, and to write herbals which set out the botanical characteristics, external appearance, and origin of medicinal plants, together with some notes as to their value in the treatment of disease. About this time also, pharmacopœias or lists of drugs used in therapeutics began to be written, the first collection of medical recipes sanctioned by civil authority and enjoined to be used under penalties by dispensers and compounders of medicines being that of the town of Nürnberg, published in 1545.

Remedies Old and New.

I have no intention of entertaining you to an historical account of the evolution of the modern pharmacopœia, nor of attempting to excite disgust, ridicule, or amusement by giving a list of some remedies which have appeared even in comparatively recent pharmacopœias—remedies such as oil of dead men's bones, powdered worms, &c. The fact is that too much has been made of these monstrosities in the therapeutic armamentarium. When we are tempted to criticise too severely the therapeutic methods of our forefathers, we should remember that they were based on current theories of pathology, which are to the modern mind not only very crude but very curious. "Men," said Edmund Burke in sarcastic mood, "are wise with but little reflection . . . in the business of all times except their own." We smile or sneer at primitive man for his belief in a charm, in a prayer or a sacrifice to a god, or in some potion brewed in mystery by the old woman or medicine-man of his tribe. We should not forget that even to-day those of us who are irrational—and most men are irrational when they are tortured by disease or the fear of death—cling just a little to a faith in magic. We still like to think that there may be something to charm away our pain, that the deity at his grotto may heal us in a supernatural way, that the mysterious patent medicine may bring about a miraculous cure. Some of us still believe in the miracles of the faith-healer, of the nature-healer, of the layer-on of hands. Such follies and superstitions are all very natural, but if man were content to rely on them alone little progress would be made. Fortunately, throughout the ages there have been those who, following Paul's advice to the Thessalonians, have tried to "prove all things" and to "hold fast to that which is good." Their number has not been great, nor their influence until comparatively recent times marked, but they have been able to fashion the science of medicine by lopping off at least some of its effete and ridiculous branches.

We saw that at the revival of learning materia medica became allied to botany, and this alliance has persisted to recent times, for less than 50 years ago drugs were arranged according to their natural orders in all text-books of materia medica. The advance of chemistry at the beginning of last century led to a more accurate analysis of the crude remedies in use, and alkaloids and other active principles of plants came to be used in the treatment of disease. New drugs and new combinations of old drugs were introduced into practice, and toxicology or the effects of poisonous doses of drugs began to be studied on man and on animals. But all this was merely an advance in method and efficiency. It indicated no fundamental change in principle. The teaching of materia medica in the medical schools advanced but little, and up to comparatively recent times too much attention was paid to its descriptive or botanical side. There are certain drugs which every medical man ought to be able to recognise, but it must hav been a wearisome task for the student of 50 or 6 years ago, eager to learn something of the actio and uses of the drugs which he was to employ in h practice, to sit through lectures devoted mainly t a minute description of the appearance, physic characters, and preparations of those remedies.

We must not be tempted, however, to blame ou predecessors too much. Human progress, medicall as well as politically, is never uniform along a unbroken front. One science is often held up becaus the sciences ancillary to it have not progresse sufficiently far to make a general advance possibl And what medicine needed to go forward by leaps an bounds was improved education, a large developmer of the scientific spirit, and a consequent great advanc in the fundamental sciences. All this has happene since the middle of last century. Physics gave u instruments of precision hitherto undreamt o Chemistry added to our pharmacopœia a large numb of potential drugs, and also made it possible to stud the chemical changes occurring in the body; an in biology there was an amazing outburst of activit in many fields. The genius of Pasteur and Koc founded the new science of bacteriology, and revol tionised our whole outlook and therapeutic aspirations in infectious diseases. Experiment physiology, under the inspiration of Claude Bernar began to move to the forefront of scientific interes and gave to observational or Hippocratic and al to empirical medicine the powerful instrument of th experimental method, and what is of great importance, the experimental spirit. All this ha a profound effect on materia medica. It compell the pure empiricist to attempt to answer two importa questions: (1) Is there a causal relationship betwe the giving of the drug and the cure of the disease?- often a very difficult point to decide. (2) How do the remedy act, and what light does it throw on th mechanism and nature of the pathological process

Pharmacology.

This union of traditional materia medica with th experimental spirit led to the birth of modern pharm cology or pharmacodynamics, as it is sometim called. Majendie, that pitiless critic and scepti was one of the first to investigate systematically th action of remedial agents, and since then workers many parts of the world have followed his exampl and in the same spirit. At first, pharmacologic research was naturally directed towards analysi the mode of action of drugs in familiar use, and the is no question but that the increased knowledg obtained in this way led to increased accuracy the employment of drugs in the treatment of diseas and also to a better understanding of disease process themselves. Experimental pharmacology also, association with synthetic chemistry, introduced in the clinical domain many drugs of first-rate importan —amyl nitrite, chloral and its derivatives, nearly a the hypnotics and analgesics, and in more rece times, many of the hormones—adrenalin, pituitri insulin. It is beside the point to say that some of the came from the laboratory of the chemist and of th physiologist, not from the workshop of the profession pharmacologist. Those who argue in this way ha missed the significance of the whole trend of mode scientific thought—the essential unity of biologic science, especially in its relationship to medicin Every student of medicine is concerned with th reactions of living structures to the chemical an physico-chemical changes of their environment, th is, with pharmacology, biochemistry, physiology, an

pathology. It is impossible to establish boundaries between these subjects, and indeed in my view it is inadvisable to attempt to do so. But whatever we may call ourselves—physiologists, pharmacologists, pathologists, clinicians—we are first and last biologists, and we must realise that our own special subject is not so much a field as a focus of interest.

For the student of medicine there is no better connecting link between the basic and the clinical subjects than pharmacology. Consider its position in the curriculum. The student comes to it after completing his courses in anatomy and physiology, and he meets for the first time the chief weapons he is to use in his life's work. He feels that now he is making a real step in the direction of his final goal. He finds that pharmacology articulates with physiology, with pathology, and, most important of all, with clinical medicine and surgery. The function of the conducting tissue of the heart, for example, may have appeared to him merely as interesting, but now it assumes an added importance, for he learns of digitalis which acts specially on this tissue to depress its conductivity, and he begins to understand how the drug can be of supreme value in the treatment of certain pathological conditions leading to cardiac failure, and how modern research has given a rational explanation of what was at one time an "old-wife's" cure.

Divorce of Pharmacology from Therapeutics.

It is not surprising that experimental pharmacology which is so important, not only for the therapeutist but even for the physiologist and the pathologist, should have tried to raise itself more and more to the position of a pure science. But this unfortunately led to the break-up of the union of materia medica and the practice of medicine which had existed, as we have seen, since the origin of man. The pure science of pharmacology and the applied science of therapeutics became divorced. The gap between the laboratory and the clinic got wider and wider. This is a matter which has given rise in recent years to much controversy, and though it is difficult to keep clear of a natural bias, the matter demands some discussion.

The argument usually advanced to warrant the separation is that no one man in these days can follow the progress of clinical practice and of laboratory research with satisfaction to himself or profit to his students; and this argument has been carried to its logical conclusion in some of the American universities where the professor of pharmacology has no clinical knowledge, and may even have no medical qualification. Such an argument does not, however, take into account the fact I have already emphasised, that the study of medicine is the study of biological science, and that pharmacology is simply a focus of interest in that science devoted chiefly to the study of the action of drugs and remedial agents. And since, as is generally admitted, the ultimate object of pharmacological research is the healing of the sick, surely it is at least as important to study the action of remedial agents on the sick as it is to analyse their effects on healthy animals. No one will deny that there are many aspects of pharmacology which can be studied without reference to or knowledge of clinical medicine, and that great and good work has been and will be done under these circumstances. As in all other sciences, men can investigate with no ulterior motive save that of the simple acquisition of knowledge. Their work may not be immediately applicable to practical needs, but it will deepen and strengthen the foundations on which therapeutics is built. Like Saul, they may go forth to seek for asses and find a kingdom. But that does not mean that applied science should be neglected. The great Pasteur, immersed as he was in the researches which led to the greatest single change, and probably the most far-reaching one, which has ever taken place in medical theory, was constantly engaged in the solution of practical problems; and who shall say what mental stimulus he received from his practical work. Two views, diametrically opposed, have been held regarding medicine, as indeed regarding everything else worth while, since man could think at all. One is that theory is useless, that practice is the thing; the other, that practice is effete, and that the initiative has passed from the practical man to the theorist—in medicine, from the clinic to the laboratory. Both views are wrong. It is natural perhaps that much of the popular praise should fall to a man who makes an important therapeutic discovery. He is the immediate and obvious benefactor of mankind. But in the great enterprise of medicine it is vain for any special class of worker to arrogate the credit of most discoveries to his own class. It is foolish to attribute to a mere company the victory which rightly belongs to a whole army working in combination. It must never be forgotten that ideas freely current help to keep science fresh and living, and that pure science always receives stimulation and renewed vitality from its contact with practical problems. Physiology, in natural pride of its triumphs as a pure science, is apt to forget that it owes some of its greatest advances—namely, the idea of cerebral localisation and the idea of internal secretion—to its relation to medicine. How much more, then, will contact with clinical medicine give to pharmacology a fresh flow of ideas to invigorate and stimulate it! Apart altogether from such general considerations it must always be kept in mind that the great majority of the students of medicine intend to practise medicine, and are not concerned with pharmacology as a pure science; they study it to enable them to forge and to use the weapons required to counteract symptoms and cure disease. In my considered judgment, therefore, pharmacology in its widest sense can not and should not be studied exclusively either at the bedside or in the laboratory. Theory and practice must not be divorced.

Training for Medicine.

We must determine now, if we can, how our subject may best meet the needs of medical education and medical practice at the present time. From most of you society will not demand proofs of learning; it will not be interested in the physiological, anatomical, pathological, or chemical notions you may have acquired. It will want to know only if you can apply your knowledge to the treatment of disease. The whole aim and object of the medical curriculum is to teach students to treat disease rationally. It might be expected, therefore, that a great deal of attention would be paid in medical schools to the teaching of therapeutics, yet in actual fact little or no attempt is made to correlate systematic instruction in the principles and practice of rational treatment with clinical medicine. The fault lies, I think, in that the great advance which has been made in diagnostic methods during the past few decades by the application of biochemical, serological, and physical principles has taken hold of the minds of clinicians to far too great an extent. The result has been that, in the clinic, when the history and physical signs have been elicited, the diagnosis, differential

diagnosis, and prognosis discussed, and the pathological aspect of the disease fully considered, the all-important question of treatment is either ignored or is dealt with in such a perfunctory fashion that the student carries away no clear idea of the method of treating a similar case. The same applies to the clinician's attitude to therapeutical research. If his outlook is still dominated by the old views of pathology, his chief interest lies in the post-mortem room, and he regards his treatment merely as a means to placate the patient. In short, he is that pious fraud, the therapeutic nihilist. If, on the other hand, he is an enthusiast in treatment, he never fails to ascribe his good results to drugs, or vaccines, or ultra-violet radiations, or vitamins, though he has probably used so many agents in the one case that he would find it difficult to say which one had proved really valuable. And yet there is so much to be done. Each and every day in the practice of medicine an enormous amount of treatment is carried out, yet very little systematic attempt is made to determine fundamental laws, to bring to the clinique the spirit and methods of the laboratory, and to find out just what the drug is doing and how it acts. There are great difficulties in such researches, apart from the obvious difficulty of adequately controlling the experiments. But the effort would be well worth while. Even though it did not add one single positive element to therapeutics, it would render an enormous service if it helped to clear away the overgrowth of useless treatment, and let us see where we really are. Nothing is more needed in medicine than a vigorous and informed criticism, based on accurate and detailed examination of the effect of drugs and other remedial agents on patients.

Proprietary Remedies.

And that brings me to a cognate subject. The discovery of the therapeutic possibility of synthetic chemicals, patented and therefore proprietary, and the development of other products of the laboratory, vaccines, sera, endocrines, and vitamins, combined with the natural eagerness of the physician to help his patient, have led in recent years to a great deal of empirical treatment with these agents. Their origin in the scientific laboratory has been used to give a pretence of respectability to all kinds of misleading and uncritical statements in medical journals and by the profession, as well as in the trade journals devoted to their advertisement, which pour in daily on medical men. In fact, there has arisen in this country a condition of affairs not unlike that described by Sollman as existing in America in 1905. At that time, he said, the general practitioner, without the time or material for discriminating study, assailed on all sides by the laudatory literature of the advertising pages, and occasionally impressed by the fashionable consulting physician who was always looking for something new in therapeutics, was a helpless and easy victim for the skilful proprietor. I doubt if practitioners in this country are such easy victims, but the tendency is that way. A friend of mine, a general practitioner, wrote to me recently on this very subject. He complained that he and his colleagues were constantly being imposed on by attractive boosting of proprietary preparations, and he asserted that one of the clamant needs of the profession was for some authoritative statement as to how to discriminate between good and bad in drug advertisement. The American Medical Association attempted to deal with the situation by establishing the Council on Pharmacy and Chemistry. Not content with destructive criticism only, it gave attention to the constructive side. It issued a book, "New and Non-official Remedies," which is revised annually and which tries to give reliable information as to the action and uses of new drugs. In recent years the Council has taken up the logical position that the approximate value of a new drug should be determined accurately on patients as well as on animals before it is advertised to the profession. It would be too much to expect that the labours of the Council would free America from blatant advertisement and extravagant claims, but it has done good work, and the establishment of a commission along similar lines might be of advantage to this country.

But that, in my view, would not be enough. The student of to-day is the practitioner of to-morrow, and what is required more than anything is to interest him in exact therapeutic observation and experiment. He should not be kept in ignorance, as he so often is, of the medicinal or other treatment the patient is receiving. He should be required to observe for himself the effect, either immediate or remote, of remedial agents. He is usually told about these matters, but he should be encouraged to observe and to try to draw his own conclusions. He should see for himself that some diseases tend of themselves to get well, that others can be cured by therapeutic measures, that some can only be alleviated, and that certain of them in the present state of knowledge are hopeless. He should learn that treatment must be carried out according to a plan, and not in a haphazard fashion, and that each case presents in itself an interesting and important physiological and pathological experiment. In that way his critical powers will be developed, and without running the risk of falling into the pit of therapeutic nihilism, he will get an accurate knowledge of the success or partial or complete failure of therapeutic measures. It seems to me common sense that the student should have this experience before qualification rather than after, and I cannot understand why such a policy is not more generally adopted, for in a not inconsiderable experience of clinical teaching, I have found that there is nothing which interests the student more than to feel that he is taking part in the treatment of the patient. Credulity is the child of ignorance, and better teaching in therapeutics will go a long way to checking the influence of the advertising agents of new drugs, though of course it will never completely abolish it.

Education and Research.

The purport of my discourse will now be obvious. Materia medica in its widest sense—pharmacology, pharmacodynamics—call it what you will—is the science on which sound therapeutics is and always must be based. It should not be divorced from the practice of medicine. To my third year students, therefore, I propose to teach pharmacology as an applied science, always with the view to bringing it into relation with general medicine; and to final year students I intend offering a voluntary systematic course in the principles and practice of rational treatment. I hope to do more. The authorities of this university have realised that a clinical appointment is an essential adjunct to the chair of materia medica, and though my duties as extra-honorary physician to the Royal Infirmary are at present nominal, I hope that I shall soon have an opportunity of putting into practice the pedagogic principles I have preached to-day. My aim, in short, will be not only to abolish the artificial barrier which has been set up between the clinic and the laboratory, but to help to turn out students of medicine with a sound and critical first-hand knowledge of the treatment of disease.

One final word regarding the future. It has often been said that if we just knew more of the cause of disease we would be able to treat it better—that research in therapy must lag behind research as to causation. Not a bit of it! We have known the cause of tuberculosis for more than half a century, we think we know the ætiology of pneumonia, yet our method and means of curing both these diseases are sadly lacking in efficiency. They are much the same, in fact, as they were when Hippocrates laid down his regimen. On the other hand, long before the malarial parasite and quinine were dreamt of, cinchona bark was being skilfully employed in the sound and successful treatment of malaria. And to-day, though we are entirely ignorant of the real cause of rheumatic fever and pernicious anæmia, we have almost specific remedies for these diseases. Therapeutics, therefore, can advance on its own, provided new chemical substances and new biological products are placed at its disposal. In Germany, institutes of experimental therapeutics have been established, where chemist, physiologist, bacteriologist, and the experimental and clinical pharmacologist form a team for the production of new drugs and for their experimental and clinical trial. We in this country prefer not to be regimented in that way. Our genius appears to run more in the direction of individualistic effort. Yet it might be possible for the members of the different departments of our medical school to cooöperate in work which may not only advance the reputation of this ancient university, but also help in the solution of the fundamental medical problem, the prevention and cure of disease.

INTRASACRAL EPIDURAL INJECTION IN THE TREATMENT OF SCIATICA.

By William Evans, M.D., M.R.C.P. Lond.,
MEDICAL FIRST ASSISTANT AND REGISTRAR, LONDON HOSPITAL.

Although it is the purpose of this paper to describe the results obtained in the treatment of sciatica by intrasacral epidural injection, it is necessary at the outset to examine briefly the theories that have been advanced by different writers to explain the nature and mechanism of production of sciatic pain. This preliminary review is introduced in order to emphasise the difficulty experienced in allocating the series of cases discussed in this paper to any group or subdivision other than that of *primary* or *idiopathic* sciatica, and also to determine how far one is able to regard the response to this form of treatment as throwing some light on the ætiology of sciatica.

The nomenclature adopted in the definition of the varied forms of sciatica is in a state of chaos. Most writers seem to recognise two distinct types: (1) *primary, idiopathic,* or *essential* sciatica, and (2) *secondary* or *symptomatic* sciatica. In the latter group are placed all cases in which pain in the course of the sciatic nerve results from pressure on the nerve or its roots by neoplasms situated in the pelvis or by disease occurring in the hip-joint, sacro-iliac joint, and lumbosacral vertebræ. In a large group of cases no pressure lesion can be demonstrated, either by ordinary clinical means or with the aid of special methods of investigation; these have been referred to as instances of primary or idiopathic sciatica. The true ætiology of sciatic pain in this group of cases remains obscure, and it is in the attempt to allot to them their particular cause that speculative terminology has been introduced.

Sicard [1] adopted a classification of sciaticas based on anatomical lines and, according to the site of the lesion, referred to them as *high, middle,* or *low* sciatica. In the middle and low varieties the lesion producing the neuralgia is situated in the nerve plexus or nerve trunk. The term high sciatica indicates that the lesion has its site between the posterior root ganglia and the origin of the nerve plexus. Sicard applied the term *funiculitis* to this condition, and maintained that an inflammatory lesion of the bony canal through which the nerve root passes—i.e., a *neurodocitis*—was the real cause.

Danforth and Wilson [2] expressed the opinion that sciatic pain was a symptom of disturbance in the lower lumbar region of the spine, and that the lumbosacral junction supplied the commonest site of the lesion.

Putti [3] defined sciatica as a neuralgia caused by pathological conditions of the intervertebral foramina and articulations. He regarded it as a symptom of neurodocitis and lumbarthritis, and considered that the term idiopathic sciatica should be replaced by the more precise and adequate one of *arthritic* or *vertebral* sciatica, and that in order to treat the sciatica it was necessary to treat the arthritis.

Buckley [4] has recently investigated 45 cases sent to hospital with the diagnosis of sciatica. He concluded that 27 of these were cases of *secondary* or *symptomatic* sciatica, and that the remaining 18 were examples of sciatic neuritis.

In the experience of these writers, therefore, secondary or symptomatic sciatica occurs with greater frequency than the primary or idiopathic form. The results obtained from the present investigation do not lend support to this view, but indicate that when a careful survey has been made of the history of the illness, the clinical examination of the patient, and the radiological investigation of the lumbosacral region, and when hypothesis and mere speculation as to the probable cause of the neuralgia have been excluded, the majority of cases are instances of primary or idiopathic sciatica. The fact that the true nature of the lesion in these cases has remained obscure or cryptic warrants their inclusion in this group.

The Cases and their Treatment.

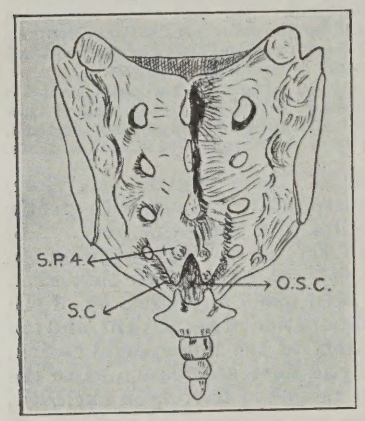
In accordance with the definition outlined in the previous paragraph, the 40 cases discussed here have been regarded as instances of primary or idiopathic sciatica. There were 21 males and 19 females. The age varied from 20 to 66, the average age being 40 years. The sciatic pain in all cases had been sudden in its onset, and had continued without intermission for periods varying from 5 days to 18 months; the average duration of symptoms was five and a half months. In all the 40 cases the neuralgia was confined to one side, and occurred in the right limb in 25 and in the left in 15. The pain, which was most severe in the thigh, radiated in the distribution of the sciatic nerve. There was no history of strain or injury, and no clinical evidence of disease in the lumbosacral part of the spine, and radiological examination in 15 cases failed to reveal any pathological changes in this region. Stretching of the affected sciatic nerve following flexion at the hip with extension of the knee produced pain (Lasègue's sign) in 39 cases. Tenderness on deep pressure over the nerve trunk was elicited in 30 cases; the degree of tenderness is indicated in the tables. The ankle-jerk was absent in eight and diminished in six cases. Septic teeth were found in nine cases. Large and hypertrophied tonsils were present in two cases. Treatment in the form of internal administration of drugs and external application of counter-irritants had been adopted in all the cases, but had proved of no avail. Massage, ionisation, electrical therapy, hot baths, stretching the nerve under general anæsthesia, injections of oxygen or saline along the course of the nerve, and splinting the affected limb were forms of treatment which had

been applied to some of the cases, but had produced no amelioration of the symptoms.

TECHNIQUE OF INTRASACRAL EPIDURAL INJECTION.

The patient lies on the affected side with thighs and legs slightly flexed. The triangular outlet of the sacral canal is then defined in the following way. The tip of the coccyx is first located, and the palpating finger is made to slide upwards towards the sacrum for a distance of about 2 inches. At this point on either side of the mid-line the prominent cornua of the sacrum can be readily felt in most cases. Above the cornua the imperfect laminæ of the fifth sacral vertebra are found to converge to form the apex of the triangular outlet of the sacral canal. The mid-point between the two sacral cornua marks the site of the injection (Fig. 1), and an arrow pointing to this spot should be outlined on the skin by means of a grease pencil. The skin and the track of the needle is then infiltrated with 2 per cent. novocain, and sufficient time is allowed for the production of efficient local anæsthesia. A lumbar puncture needle is then introduced into the sacral canal. After penetration of the skin the needle should assume the direction indicated by arrow A in Fig. 2 in order to transfix the sheet of tough fibrous tissue that roofs over the outlet at this site. Immediately the point of the needle penetrates this tough sheet its direction should be changed as indicated by arrow B in Fig. 2; it is then advanced for an inch. A syringe is applied to the needle, and an attempt is made to withdraw the piston for a short distance. If cerebro-spinal fluid is aspirated the needle has been advanced too far and must be withdrawn a short distance. This precaution is necessary in order to ensure that the point of the needle lies in the sacral canal outside the spinal theca. The sterile solution, previously warmed to body temperature, is then introduced slowly by means of a 25 c.cm. syringe. The operation throughout must be conducted under aseptic precautions. The patient should rest quietly on the affected side for half an hour, and remain recumbent for 24 hours after the injection.

FIG. 1.



Showing the anatomical boundaries of the outlet of the sacral canal (O.S.C.). S.P.4 = spinous process of 4th sacral vertebra. S.C. = sacral cornu.

SUBJECTIVE SYMPTOMS DURING THE INJECTION.

All the patients experienced a feeling of distension or discomfort, but few of actual pain in the sacral region at the time of the injection. These symptoms became aggravated towards the end of the operation, when considerable pressure was required in the introduction of the fluid. Headache, which was present in a few cases, was never severe. Many of the patients experienced much pain in the distribution of the affected sciatic nerve, and as this symptom appeared to indicate that the nerve was being stretched it was thought that its presence in any particular case predicted a favourable result. Further experience did not confirm this view, but showed that this sign did not appreciably influence the prognosis. Where over 100 c.cm. of 1 per cent. solution of novocain had been injected, the patients occasionally experienced abnormal sensations or paræsthesiæ, such as formication. A few said that they had found it difficult to control a desire to shout or scream. These sensations, although uncomfortable, were never serious, and usually lasted for only ten minutes after the injection. Alarming symptoms occurred in only one instance, wher cyanosis, opisthotonos, unconsciousness, and incon tinence of urine and fæces followed the injection o

120 c.cm. of 2 per cent. solution of novocain; co sciousness returned within half an hour; sphinct control was re-established 12 hours later, and recove was complete.

RESULTS OF TREATMENT.

To facilitate the study of the results, the 40 cas are placed in four groups, as indicated in the table Cure resulted in 22, or 61·1 per cent. Improveme occurred in 5, or 13·9 per cent. The treatment fail

QUANTITY AND NATURE OF THE FLUID INJECTED.

Between 60 c.cm. and 145 c.cm. of fluid had been introduced into the sacral canal in those cases where cure of the sciatica followed epidural injection; the average quantity injected was 98 c.cm. An average of 100 c.cm. was used in the cases where improvement of the symptoms followed the injection. In the cases where the injection failed to alleviate the sciatic pain, an average of 110 c.cm. of fluid had been used. These figures, together with those recorded in the tables, suggest that success does not depend on the quantity of fluid introduced. The amount of fluid recommended for injection is from 60 c.cm. to 80 c.cm. It was rare to experience any degree of resistance to the introduction of the solution until the quantity injected had exceeded 60 c.cm.

Forty-seven injections were given in the 40 cases discussed in this paper, the injection being repeated in seven cases. Normal saline was used in six cases, 1 per cent. novocain in 17, and 2 per cent. novocain in 3 cases; in 21 cases the first 20 c.cm. to 30 c.cm. of the fluid injected consisted of 1 per cent. novocain, and this was followed by normal saline. A study of the results indicates that relief from sciatic pain is in no way dependent on the nature of the solution introduced. Of six cases where normal saline was used, immediate and complete cure followed the injection in five.

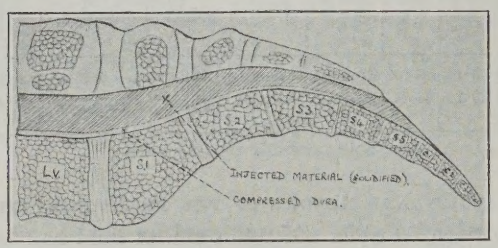
How Pain is Relieved.

From clinical observation it was difficult to see the exact manner in which intrasacral epidural injection cured sciatica. The fact that some of the patients experienced pain in the course of the affected sciatic nerve during the injection, and also that normal saline appeared to be as efficacious as novocain solution in affording relief from sciatic pain, seemed to indicate that the introduction of fluid into the sacral canal in some way produced stretching of the sciatic nerve trunk or its roots. In the attempt to elucidate its mode of action the following investigations were conducted.

Expt. 1.—All the nerves emerging from the lumbosacral region in a cadaver were divided, and the sacrum and lower three lumbar vertebræ were removed and placed in 4 per cent. solution of formalin for 12 hours. The anatomical relationship of the lower part of the spinal theca and the nerve roots which join to form the sciatic nerve was studied in sagittal and transverse sections of the lumbosacral vertebræ. The appearances of the sections are shown in Figs. 2 and 4. The nerve roots have been divided immediately before they pass through the dural sheath. The nerve roots in their extradural course and proximal to their passage into the sacral foramina were found to measure from 1 in. to 1½ in. in length. The epidural space, which is filled with fat, is prolonged upwards in the spinal canal and invests the dural covering of the spinal cord. The ventral or anterior compartment is traversed by firm fibrous bands which bind the theca to the intervertebral discs, so that some difficulty was experienced in completely separating

the dura from its attachment or anchorage to the anterior wall of the spinal canal. In its posterior and lateral aspects, however, there is no anchoring of the dura to the bony wall, so that it was possible to separate it and to enlarge the space at the expense of displacing the dural tube and its contents forwards. This study of the sacral space and its spinal prolongation has facilitated the true interpretation

FIG. 3.

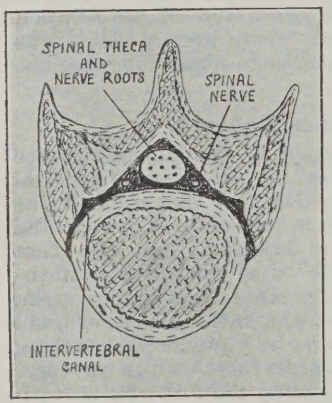


Sagittal section of the lumbo-sacral region, showing compression and anterior displacement of the dural tube and its contents following intrasacral epidural injection.

of the results obtained from intrasacral epidural injection in cases of sciatica.

Expt. 2.—It then became necessary to study the manner in which these anatomical relations became disturbed after the introduction of fluid under pressure into the sacral space; 20 g. of gelatin were dissolved in 100 c.cm. of water to which 0·5 g. of methylene-blue had been added. This mixture, when heated, could be forced through a standard lumbar puncture needle; it solidified on cooling; 50 c.cm. of this medium was injected into the sacral space of a fresh cadaver, and later an examination was made of the lumbo-sacral vertebræ in sagittal section, and of the upper part of the fifth lumbar vertebra in transverse section. The appearances are shown in Figs. 3 and 5. It was found that the injected material had separated the dura from its normal close anatomical contact with the posterior and lateral walls of the spinal canal, and had displaced it forwards and inwards. The anterior segment of the dura, in virtue of the anchoring fibres described in the previous section, was found to have preserved its close relationship with the posterior surface of the vertebral bodies. This compression of the dural tube and its contents is readily appreciated by comparing Fig. 2 with Fig. 3 and Fig. 4 with Fig. 5. These changes within the spinal canal were traced as far as the first lumbar vertebra. In cases where 100 c.cm. of the material had been injected the dye could be traced as high as the upper cervical region.

FIG. 4.



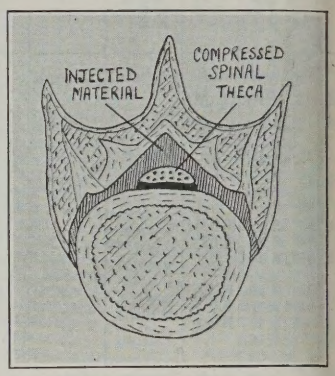
Transverse section through the body of the fifth lumbar vertebra.

The injected material, however, does not remain confined to the spinal canal, and the solidified gelatin dye mixture was found to have been forced along the vertebral foramina, forming sleeve-like projections along the course of the emerging nerves. This escape of the injected material occurs quite early during the injection, and commences when only 10 c.cm. of fluid have been introduced. It is possible that this contributes to the relief of sciatica in those cases where the pathological lesion is believed to be a neurodocitis.

Expt. 3.—The lumbosacral vertebræ were exposed in the cadaver and the dura was divided at the level of the fourth lumbar vertebra. Water was then injected into the sacral canal through the sacrococcygeal opening, and the displacement of the dura was carefully noted. Not only did the compression of the dural sheath forwards and inwards produce a stretching of the nerve roots, but also the pressure exerted by the water displaced the dural tube upwards, and in this way further augmented the stretching effect. This upward shift of the posterior part of the dural sheath and the cauda equina measured 1/10 in.

Expt. 4.—A lumbar puncture needle connected with a manometer was inserted in the space between the fourth and fifth lumbar spines in a case of sciatica where treatment by intrasacral epidural injection was in progress. The effect of the injection on the cerebro-spinal fluid pressure was then noted, and the results obtained have been plotted and illustrated by means of a chart (Fig. 6). The quantity of fluid introduced into the sacral space has been indicated on the abscissa, and the pressure on the ordinate. The continuous lines represent the rise in the pressure during each separate introduction of 2 or 4 c.cm. of normal saline into the sacral canal. The discontinuous lines represent the fall in pressure which followed each injection; this fall in pressure occurred gradually, and the resting level was only reached after an average interval of two minutes. When 30 c.cm. had been introduced into the canal the pressure remained stationary, oscillation of the fluid in the manometer ceased, and the further injection of 50 c.cm. of saline did not influence the reading. This sudden interruption in the manometric reading can be explained by the fact that the introduction of 30 c.cm. of saline into the epidural sacral space had obliterated the subdural space up to the level of the lumbar puncture needle.

FIG. 5.



Transverse section through the body of the fifth lumbar vertebra, showing the anterior displacement and compression of the spinal theca and its contents after intrasacral epidural injection of the dye.

FIG. 6.

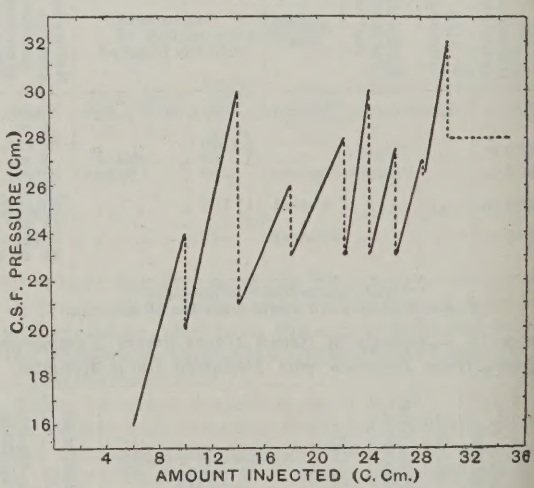


Chart to show the variation in the cerebro-spinal fluid pressure during intrasacral epidural injections.

Conclusions.

1. If mere theoretical conjecture is excluded in the differential diagnosis of the various types of sciatica it is found that the majority of cases fall into the group known as *primary, idiopathic* or *essential* sciatica.

2. Intrasacral epidural injection in the treatment of primary sciatica produces immediate and complete relief or cure in over 60 per cent. of the cases. A further 13 per cent. derive considerable benefit from the treatment.

3. Clinical results have shown that it is unnecessary to inject more than 80 c.cm. of fluid, whilst the experimental data indicate that the desired effect can be obtained from the introduction of only 30 c.cm.

4. No special advantage is derived from the use of novocain solution, and normal saline appears to be equally efficacious.

5. A mechanical stretching of the nerve roots that go to form the sciatic nerve appears to be the important factor in the cure of sciatica by intrasacral epidural injection. This conception of the modus operandi is supported by three main facts, namely: (1) Many of the patients experienced pain in the course of the affected sciatic nerve during the injection. (2) Introduction of saline into the sacral canal appeared to be as efficacious as novocain solution in alleviating the sciatic pain. (3) Visible stretching of the nerve roots was observed in the cadaver during the injection.

I am indebted to Dr. Theodore Thompson and Prof. A. W. M. Ellis for allowing me to include in my series cases admitted under their care at the London Hospital. I also wish to thank Prof. Hubert M. Turnbull for permitting me to use the material in his department for the purpose of conducting some of the experiments cited in this paper.

OBSERVATIONS ON THE METABOLISM OF HUMAN MAMMARY CARCINOMA.

BY FRANK DICKENS, M.A. CAMB., PH.D. LOND.,
WHOLE-TIME WORKER FOR THE MEDICAL RESEARCH COUNCIL;
AND
DAVID H. PATEY, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

(From the Courtauld Institute of Biochemistry and the Bland-Sutton Institute of Pathology, Middlesex Hospital.)

THE metabolic studies of Warburg and his collaborators on cancerous and other tissues have shown that the two fundamental processes occurring in cells are: (1) *respiration*—i.e., the consumption of atmospheric oxygen, the resulting oxidation of organic metabolites, and the liberation of carbon dioxide; and (2) *glycolysis*—i.e., the cleavage of the carbohydrate molecule without participation of atmospheric oxygen, leading to the production of two molecules of lactic acid from one molecule of carbohydrate.

These two types of chemical change are not independent reactions, but are related by a more or less quantitative coupling, so that an increase in the value of respiration results in a corresponding diminution in the extent of aerobic glycolysis. In most normal tissues the aerobic glycolysis is small or zero. Under anaerobic conditions the amount of glycolysis is largely dependent on the properties of growth and degeneration of the tissue, so that embryonic tissues, for example, have a high anaerobic glycolysis.

Warburg's methods have been applied particularly to a study of tumours, and the earlier work, which was done principally on transplanted rat tumours, suggested that tumours might be classified metabolically on the basis of the relation of the respiration to the glycolysis. It was thought that in tumours the respiration was too small to prevent lactic acid production. More recent work on spontaneous and transplanted mice tumours (Murphy and Hawkins, 1925; Crabtree 1929) has shown that this is not generally true. In addition to this difficulty, apart from tumours certain granulomatous overgrowths (Crabtree 1929, Dickens and Šimer 1930), as well as the retina and mammalian erythrocytes are characterised by the production of a considerable amount of aerobic lactic acid. It appears, therefore, that there is some defect in respiration in all these tissues (Warburg 1929), which defect has been shown to lie in the oxidation of carbohydrate. (Dickens and Šimer, 1930.)

It is, therefore, clear that aerobic glycolysis is not a specific feature of tumours. There is, however, a need at present for more experimental observations on comparable series of tumours to show if any generalisations may be arrived at as to the relation of metabolism to the histological and clinical details of such a series of cases. In the present paper the results obtained in a series of cases of human mammary carcinoma studied by the above methods are reported; this material comprises tumours of varying degrees of cellularity, differing in type and arrangement, and with different degrees and types of connective tissue response. The metabolic investigations were, therefore, combined with a histological study of the tumours. In addition to the tumour tissue, two portions of breast showing intraductal epithelial hyperplasia were examined, and also one case of chronic cystic mastitis and a portion of unchanged breast tissue near a growth.

Method and Results.

The breasts to be examined were obtained immediately after surgical removal. In each case a suitable portion of tumour was selected, and the metabolic investigations at once begun. As a rule, the time intervening between the removal of the specimen from the patient and the commencement of preparation of the material did not exceed 5–10 minutes, and readings were, as a rule, begun under 40 minutes after removal by the surgeon.

The improved method of Warburg (1924) was used in all experiments. The medium contained sodium bicarbonate ($2{\cdot}5 \times 10^{-2}$ molar) and 0·2 per cent. glucose. The gas mixture with which the vessels were filled consisted of 5 per cent. CO_2 in O_2 or N_2 as required. Ringer's solution was used in all experiments with the exception of numbers 1 and 2, in which inactivated horse serum containing 0·25 per cent. glucose was used. As far as possible duplicate estimations were made, and the uniformity of the tissue was controlled by changing over the large and small volumes of fluid in the two vessels used for the measurement of aerobic metabolism and continuing the measurement under these reversed conditions. If the two sets of readings were not substantially the same, the experiment was discarded, since this showed that the tissue was not sufficiently uniform.

Histological Investigation.—After the thin slices of the selected portion of the tumour had been obtained for the metabolic estimations, the remainder was fixed and blocked out for microscopical section, the surface cut being that from which the slices for the metabolic examination had been removed. In this way, a microscopical field was obtained of tissue immediately adjacent to that examined metabolically. The character and arrangement of the actual carcinomatous tissue was noted, and also

the degree and type of connective tissue response. As an index of the proportion of carcinoma to connective tissues, the number of carcinoma cells in 200 standard fields of 1/40 sq. mm. was counted, and an average per field thus obtained which was known as the "carcinoma cellularity index." In the case of the connective tissues, the amount of fibroblastic and elastic tissue reaction was noted, and the degree of small round-celled infiltration.

Results.—The main clinical and pathological features of the 20 cases examined, together with the metabolic findings, are given in the Table.

Discussion.

As will be seen from the above examples, the metabolic reactions of human mammary carcinoma correspond on the whole with those of animal tumours in showing a large amount of aerobic lactic acid production. Whereas, however, with the transplantable animal tumours one is dealing with homogeneous material almost entirely composed of tumour cells, in human material the issue is complicated by the varying cellularity of different tumours. The technical difficulties, therefore, in dealing with human tumours are greater and the figures obtained show a wider variation.

Of the factors which influence the figures, the most obvious is the relative amount of growth to stroma. Thus, in Case 6, which was a very fibrous growth with a carcinoma cellularity index of only 10, extremely small figures were obtained. On the other hand, the cases with a high carcinoma cell content such as specimens No. 7, 8, 12, and 15, with indices respectively of 78, 100, 63, and 166, show comparatively high figures.

In some cases, however, a high value of respiration and glycolysis is associated with a low carcinoma cellularity index, the most marked example of which is Case 5 B. This was a secondary axillary mass, and reference to the Table will show how out of proportion its metabolic figures are to its low carcinoma cellularity index of 8. The histological picture in this case showed extensive small round inflammatory celled infiltration around the actual carcinoma cells, and these inflammatory cells must have influenced the metabolic measurements appreciably. No. 11 is another case associated with round-celled infiltration which gives higher figures than would be expected from the number of cancer cells present. It is obvious, therefore, that such small round-celled infiltration in a tumour must be taken into account in any attempt to interpret the results quantitatively. The presence of proliferating fibrous tissue cells probably also introduces similar complications.

The majority of the cases showed a positive U-value—i.e., the respiration was small compared with the glycolysis (Warburg, 1927), but four cases—numbers 1, 9, 14 A, and 16—gave a negative U-value. In all these cases the respiration was high compared with the glycolysis, and the results are similar to those observed in spontaneous mouse tumours (Murphy and Hawkins, Crabtree). The system of classification whereby a tissue showing a positive U-value was considered to be a tumour has now been definitely abandoned by its author.

20	42	History unreliable.	3	40	—	Invaded.	1·7	2·9	7·1	+4

Explanation of Table.—Connective tissues: Fib. = fibroblast. F.t. = fibrous tissue. S.R.C. = small round inflammatory cell infiltration. Respiration: Q_{O_2} = no. of c.mm. O_2 respired by 1 mg. (dry wt.) tissue per hour. Glycolysis: $Q^{O_2}_{CO_2}$ = no. c.mm. CO_2 liberated from bicarbonate by 1 mg. (dry wt.) tissue per hour under aerobic conditions. $Q^{N_2}_{CO_2}$ = no. c.mm. CO_2 liberated from bicarbonate by 1 mg. (dry wt.) tissue per hour under anaerobic conditions. V.S. = very small. U-value: excess fermentation or $U = Q^{N_2}_{CO_2} - 2Q_{O_2}$ (see Warburg 1927).

In the few cases in which portions of breast other than those invaded with growth—4B, 14B, 18B—were examined, the figures were too small to allow of accurate measurement. This was also the case with the chronic cystic mastitis specimen—No. 19. In all these cases the proportion of cells to fibrous stroma was small.

CONCLUSIONS.

The above study shows that the metabolic reactions of human mammary carcinoma are similar on the whole to those of the more homogeneous transplanted animal tumours. The high aerobic glycolysis found in transplanted animal tumours is also found in these human tumours, but the results are more variable in the latter. The two chief histological factors which can be correlated with this variability are (1) the amount of actual carcinomatous tissue present, (2) the degree of inflammatory cell stromal reaction. Owing to the great variations in metabolism associated with these factors, it is at present impossible to attempt to correlate the clinical with the metabolic findings.

We wish to make acknowledgement for a grant from the British Empire Cancer Campaign (D. H. P.) and a whole-time grant from the Medical Research Council (F. D) which have enabled us to carry out this work.

ACCESSORY LOBE OF THE AZYGOS VEIN.

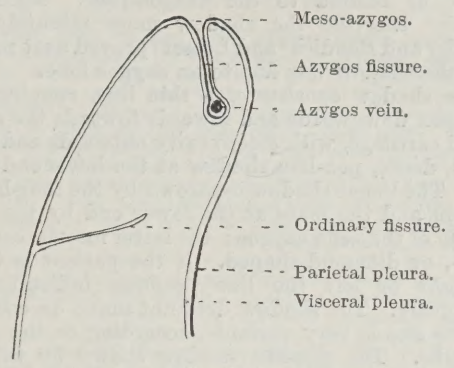
A REVIEW AND A CASE.

BY G. GREGORY KAYNE, M.D., M.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER, LADYWELL SANATORIUM.

ANOMALIES in the gross structure of the lungs, as shown by variations in the number of lobes and fissures, are common. Fissures may be incomplete or absent or, on the other hand, the lung may be divided into as many as nine lobes (Scammon[22]). All these conditions are caused by a faulty branching of the bronchial tree.

A different and rare type of anomaly is that associated with an abnormal position of the azygos vein. Normally the azygos vein runs upwards in the posterior mediastinum behind the right root of the lung and then curves forwards over the root to enter the posterior aspect of the superior vena cava immediately before the latter vessel pierces the pericardium. In the cases described here the vein is situated more laterally—behind the right lung. To reach the superior vena cava it makes a much larger curve, cutting deeply into the right superior lobe. It thus marks off an accessory lobe in the internal portion of the superior lobe. This is the "azygos lobe," more accurately termed the "accessory lobe of the azygos vein."* The azygos vein joins the superior vena cava on its lateral surface and at a much higher level than normally, almost at the level of the left innominate vein (Hjelm and Hultén[3]). As the vein sinks into the substance of the lung to reach the superior vena cava it carries with it a double fold of the parietal pleura, so that the septum, at the bottom of which the vein lies, is formed by four layers of pleura. This is shown in Fig. 1, where an ordinary septum is

FIG. 1.



After Keijser.

depicted for comparison. Hjelm and Hultén have applied the term "mesoazygos" to the triangular fold of pleura thus formed at the apex of the lung. Grüber (quoted by H. Müller[20]) has described four cases and H. Müller one case in which there was no reduplication of the parietal pleura in the fissure. Müller explained his case as due to herniation of the lung through the mediastinal pleura in the normal recess between the azygos vein and the spine. Leeser[6] made a histological examination of his post-mortem specimen, but could not demonstrate the four layers of pleura in the fissure.

The abnormality was first described by Wrisberg in 1777,† and the lobe has, therefore, often been referred to as the "lobe of Wrisberg." Since that time the condition has been noted by several anatomists and pathologists. Stibbe[23] (1919) collected 23 cases from the literature. Three further cases were reported by Cairney[15] in 1923. More recently, Hjelm and Hultén[3] and Bendick and Wessler[2] have each described two cases examined post mortem, and Leeser[6] has similarly published one case. Evidence that the condition is due to an abnormality of the bronchial tree and that the accessory lobe really belongs to the apex was given by Geddes[18] (1910) and Holtby[19] (1915), who studied the branching of the eparterial bronchus. Further, Wessler and Bendick injected the trachea of one of their post-mortem specimens with lipiodol and then showed by radiography that the azygos lobe was supplied from the eparterial bronchus and not by a separate branch from the right main bronchus.

Two opposite views on the ætiology of this condition have been brought forward. Cleland[16] (1870) suggested a very early fœtal adhesion of the lung to the chest wall, preventing the vena azygos from following its normal course. There is no evidence for the existence of such adhesions. Orth[21] (1887), on the other hand, believes the main feature to be the developmental anomaly of the azygos vein. In support of his view may be quoted (1) the fact that the insertion of the vena azygos into the superior vena cava is abnormal, and (2) the fact that Bluntschli[14] (1905) demonstrated the azygos vein already situated

* The term "azygos lobe" has also been used to name a small, pyramidal accessory lobe, which makes its appearance on the *lower* part of the mediastinal surface of the right lung. Such a lobe is constant in certain mammals.[17] For the sake of brevity the name "azygos lobe" will be employed in this article in place of the more cumbersome "accessory lobe of the azygos vein."

† His case also demonstrated an accessory lobe on the left side, due to an abnormality of the left superior intercostal vein.

laterally in a 10·5 mm. embryo. Suess[11] suggests that heredity may play a part.

Radiological Appearances.

Wessler and Jaches,[13] in 1923, described a "unique" linear shadow which they occasionally saw in films of the upper lobe of the right lung. They could not explain it, but in 1927 G. Velde[12] suggested that it might be related to the azygos lobe. Hjelm and Hultén[3] describe the shadow more minutely, and Wessler and Bendick[2] and Leeser[6] proved post mortem that the shadow was due to an azygos lobe.

The shadow consists of a thin line, running from the apex downwards and inwards towards the second costal cartilage, with a convexity outwards and a very small, dense, pea-like shadow at the lower end of the line. The linear shadow is thrown by the four-layered septum and the mass at the lower end by the cross-section of the vena azygos; the latter may be comma-, bean-, or diamond-shaped. If the patient is turned to right or left the line becomes indistinct and disappears. The shadow does not move on coughing and its size is very variable, according to the size of the lobe. The pea-like shadow shown by the vein may be absent or difficult to define when it is close to hilar shadows or to mottling.

Frequency.

In the anatomical section 31 post-mortem cases were traced in the literature. In the appended table are analysed the figures given by authors since 1927 in their reports on cases recognised radiologically.

Author.	Cases.	Films examined.	Per-centage.
Velde	5	Not stated.	—
Hjelm and Hultén	13	3,000	0·43
Mather and Coope* [8]	5	3,000	0·16
Suess	1	120	0·83
Litten [7]	6	8,000 (1½ years).	0·07
Stoloff [10]	6 (children).	Not stated.	—
Leeser	12 "at least"	,, ,,	—
Illig [4]	1	17,000 (7 years).	—
,,	12	1 year (1928).	—
Keijser [6]	10	3,500	0·28
Minehart [9]	13	About 10,000.	0·13
Wessler and Bendick	"About" 50.	15 years.	—

* 3271 films examined, but in 271 there was extensive mottling in the upper lobe and they were therefore excluded.

It is thus difficult to estimate the frequency of the condition, but it is obviously rare.

Pathology.

The azygos lobe is liable to the same pathological changes as other parts of the lung. A very small lobe may be due to atelectasis. H. Müller [20] reported a case in which pressure from a mass of leukæmic glands caused marked bronchiectasis of the whole azygos lobe; Keijser mentions one of tuberculous infiltration in the azygos lobe only. Other cases recorded have shown effusion in the fissure and infiltration of the lobe.

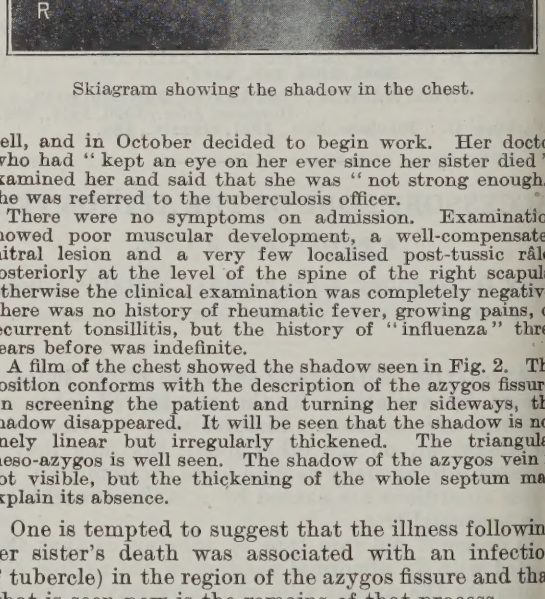
The shadow may be confused with normal lung markings, local pleural thickening or a fibrous band in the lung. The shadow of the vein may be mistaken for a hilar node or a node resulting from fibrosed infiltration. If the parenchyma does not "light up" well there may be difficulty in distinguishing an azygos lobe from widening of the mediastinum due to tuberculous adenitis (especially in children), tumour, dermoid, persistent thymus or retro-sternal goitre, or even idiopathic dilatation of the œsophagus.[1]

ILLUSTRATIVE CASE.

The following case is of particular interest as i shows a pathological thickening of the azygos septum

A girl, aged 16, was admitted to the North Wales Sana torium on Jan. 24th, 1930. She had had measles at the ag of 10 and "flu" at the age of 13. A sister had died o pulmonary tuberculosis in January, 1929. The patient, wh had lived with the sister in the same house during the whol of the latter's illness, had been quite well until January, 1929 when she had a "nervous breakdown." She "did not lool well" and lost weight. There was no cough. She remaine away from school for three months; improved considerably and returned to school until August, 1929. She remaine

FIG. 2.



Skiagram showing the shadow in the chest.

well, and in October decided to begin work. Her docto (who had "kept an eye on her ever since her sister died" examined her and said that she was "not strong enough." She was referred to the tuberculosis officer.

There were no symptoms on admission. Examinatio showed poor muscular development, a well-compensate mitral lesion and a very few localised post-tussic râle posteriorly at the level of the spine of the right scapula Otherwise the clinical examination was completely negative There was no history of rheumatic fever, growing pains, o recurrent tonsillitis, but the history of "influenza" thre years before was indefinite.

A film of the chest showed the shadow seen in Fig. 2. Th position conforms with the description of the azygos fissure On screening the patient and turning her sideways, th shadow disappeared. It will be seen that the shadow is no finely linear but irregularly thickened. The triangula meso-azygos is well seen. The shadow of the azygos vein i not visible, but the thickening of the whole septum ma explain its absence.

One is tempted to suggest that the illness followin her sister's death was associated with an infectio (? tubercle) in the region of the azygos fissure and tha what is seen now is the remains of that process.

I am indebted to Dr. D. A. Powell, principal medica officer, King Edward VII. Welsh National Memorial Associa tion, and to Dr. D. W. Fenwick Jones, medical superinten dent, North Wales Sanatorium, for permission to publis the notes and X ray photograph of the case.

CLINICAL AND LABORATORY NOTES

THE UREA CONTENT OF THE CEREBRO-SPINAL FLUID IN STATUS EPILEPTICUS.

A NOTE ON FOUR CASES.

BY OLWEN R. BINYON, M.B. LOND.,
ASSISTANT MEDICAL OFFICER, LINGFIELD EPILEPTIC COLONY;
AND
J. TYLOR FOX, M.D. CAMB., D.P.M.,
MEDICAL SUPERINTENDENT.

THE following are notes of four cases observed during status epilepticus.

CASE 1, a female, aged 13½ years, had a family history of "eccentricity" on the father's side. Her elder sister was an epileptic. She had had scarlet fever when aged 8 and after first fit when aged 10, and had had major fits, "absences" and periods of severe mental abnormality. When admitted to Lingfield in August, 1927, she was aged 10½ and had no sign of organic disease in the central nervous system or elsewhere. During the first two months after admission she had frequent attacks, both major and minor, often followed by very abnormal mental conditions. With grs. 30 of bromide daily, the attacks settled down to two majors a month and a few momentary "absences"; there was corresponding mental improvement and the intelligence quotient rose from 74 to 85.

Early in June, 1930, she complained of a cough and looked ill. She had lost 12 lb. in a month. There were no signs in the chest, but she ate little and seemed to lose interest in everything. She complained of headache and giddiness. All reflexes were normal and equal; the pupils were equal and reacted to light. Ophthalmoscopy showed the left disc rather redder than the right, but nothing else abnormal. The urine contained no sugar or albumin. On June 12th pyrexia appeared, and the temperature rose steadily until the night of the 17th, when it was 105·4°, just before death. The pulse-rate rose with the temperature from 120 to 160, and the respirations, which were shallow and irregular throughout, from 28 to 60 and over. During this period the patient was mostly comatose, but at times there was some degree of consciousness, and she was capable of slight response. The limbs were flaccid and the tendon reflexes absent, but there was a good deal of twitching of the eyelids and face muscles, and occasionally of the limbs. Oscillatory eye movements were almost continuous. Urine was passed at regular intervals throughout. During the last 24 hours there were signs of œdema of the lungs.

Permission was not obtained for a post-mortem. Lumbar puncture on June 17th gave a clear fluid under normal pressure. There was no increase in cells, and no organisms were seen in direct films. Cultures were sterile on all media. The fluid showed an increase in the urea and glucose contents:—

Protein	15 mg. per 100 c.cm.
Chlorides	725 " " " "
Urea	70 " " " "
Glucose	127 " " " "

CASE 2, a male, aged 7 years and 11 months, did not walk or talk until he was 2 years old. He had measles when aged 4 years. His first fit at 6½ may have been caused by fright. Besides frequent isolated attacks, he had five attacks in which convulsions continued for several hours. He was treated with gr. 1 of luminal and grs. 8 of bromide a day, but "not much improvement" was reported. On admission on May 22nd, 1930, his general physique was good and nothing abnormal was found in the central nervous system, heart, lungs or kidneys. He was restless, talkative, and mischievous. During the first few weeks he had a few attacks of petit mal.

On June 18th he had very violent major convulsions lasting for 2½ hours. He was treated by repeated enemata, and one dose of luminal sodium, grs. 3, hypodermically. His pulse was rapid and very weak, and his temperature rose to 103·8°. He never completely regained consciousness and died in coma on July 5th—i.e., 17 days later. During the intervening period there was continual pyrexia. For the first four days the temperature averaged 100°; later it was higher, occasionally reaching 103° and rarely dropping below 100°. The pulse-rate ranged from 130 to 160. The respiration-rate varied with the pulse, and only at the very end exceeded 40. Minor attacks varied from slight opening of the mouth, followed by moaning, to rigidity of the right or left arm and leg, accompanied by protrusion of the tongue and dilatation of the pupils. Constant side-to-side movements of the eyes were observed, with occasional fixation to the right, to the left or centrally. In the early stages there was some left internal strabismus. The pupils were equal and reacted to light, and ophthalmoscopy showed nothing abnormal. Except during the attacks, the limbs were flaccid and the tendon reflexes exaggerated and equal. A double extensor plantar response was obtained once after a series of attacks. The bladder emptied itself at intervals and was never unduly distended. A specimen of urine obtained the day before death showed a trace of albumin. At first the patient was able to swallow a little fluid, but later was fed per rectum and then through a nasal catheter. Life was undoubtedly prolonged by strophanthin given hypodermically. Repeated examination of the lungs was negative.

Post-mortem examination.—There was general emaciation, some fluid in both pleuræ, a small infarct in the lower lobe of the right lung, and a small patch of bronchopneumonia at the left base. The heart-muscle was flabby and rather pale. The liver showed an early nutmeg pattern. The kidneys were normal. A very large amount of fluid escaped on opening the dura. Sections from the cortex of the motor area and cerebellum, and through the pons and medulla, showed no histological abnormality. The cerebro-spinal fluid, taken by lumbar puncture on June 27th—i.e., nine days after the status and eight days before death—showed no raised pressure or cellular increase. The chloride, urea, and glucose contents were increased:—

Protein	15 mg. per 100 c.cm.
Chlorides	936 " " " "
Urea	172 " " " "
Glucose	157 " " " "

CASE 3, a male, aged 35, had his first fit at the age of 8. His father had died of phthisis, his mother of bronchopneumonia, and both grandfathers of asthma. He was admitted to Lingfield in January, 1906, aged 11. There was then no sign of organic disease in the central nervous system or elsewhere. He was liable to frequent typical major fits, latterly averaging rather over one a week. Usually these occurred singly, but occasionally as many as six were recorded in 24 hours. He took grs. 2 of luminal sodium daily for the last seven years of his life. His general physique was poor and progressive mental deterioration occurred.

On July 20th, 1930, he had 9 major fits; he had 4 more on the 21st, 12 on the 22nd, 37 on the 23rd, and 36 on the 24th. After this, coma alternated with periods of restlessness and shouting, and he died on the 27th. Pyrexia did not begin until after the last fit, but the temperature then rose steadily, reaching a maximum of 108·4° shortly before death. The pulse- and respiration-rates rose with the temperature. There were no localising signs of trouble in the central nervous system. While fits were occurring, a total of 6 c.cm. of somnifaine was given intramuscularly. The bladder emptied itself at intervals throughout, and a specimen of urine towards the end showed a little albumin and some blood.

Post-mortem examination.—The lungs showed congestion and an early stage of pneumonia at both bases. There was no excess of fluid in the brain. The liver showed no histological abnormality, except very slight intercellular fatty degeneration. Both kidneys showed a marked degree of cloudy swelling of the tubules. This was comparatively recent and there was nothing to suggest any form of subacute or chronic nephritis. It would, however, account for diminution of function. The Malpighian bodies of

the spleen were much smaller than normal and blurred in outline; in parts they were difficult to distinguish from the splenic pulp. The pulp itself was scattered throughout with recent and old hæmorrhages and also leucocytic infiltration, mainly polynuclear in type. Thrombosis of some of the smaller veins was evident. The endothelial cells lining the pulpar sinuses were scanty and nowhere in proliferation. The fibrous tissue framework of the spleen was normal.

The cortex of the motor areas showed no histological abnormality. Lumbar puncture on July 25th showed a clear fluid under normal pressure, with no cytological or bacteriological abnormality. A marked rise in the glucose and a slight increase in the urea contents were present:—

Protein	20 mg. per 100 c.cm.
Chlorides	725 ,, ,, ,, ,,
Urea	38·52 ,, ,, ,, ,,
Glucose	118 ,, ,, ,, ,,

CASE 4, a male, aged 27, had his first fit when aged 7. It was supposed to have followed a shock. He had major attacks every two or three weeks. He was admitted to Lingfield in November, 1921, aged 18. A trace of albumin was present on admission, but otherwise there was no sign of organic disease in the central nervous system or elsewhere. After admission he was subject to a large and increasing number of major and minor attacks and to serial major fits; later, attacks of true status became increasingly common, and he deteriorated mentally and physically.

On August 20th, 1930, he had 46 major fits in a period of two hours, without regaining consciousness. The temperature rose to 101·4° and he was obviously very ill. Treatment consisted of washing out the rectum and the administration of 3½ c.cm. of somnifaine intramuscularly and grs. 4 of luminal sodium hypodermically. One hour after the fits had stopped lumbar puncture was performed, and a clear fluid obtained, under no great increase of pressure. At the same time a sample of blood was taken from a vein. A high leucocytosis was found:—

Polymorphonuclear leucocytes	78 per cent.
Large lymphocytes	5 ,, ,,
Small lymphocytes	5 ,, ,,
Hyalines	1 ,, ,,
Eosinophils	1 ,, ,,
Myelocyte group	10 ,, ,,

The blood-urea was 32·74 mg. per 100 c.cm., and the blood-sugar, 0·092 per cent. The cerebro-spinal fluid was clear without clot, there were 2 lymphocytes per c.mm. and no organisms. The urea was a little low:—

Protein	15 mg. per 100 c.cm.
Chlorides	748·8 ,, ,, ,, ,,
Sugar	71·5 ,, ,, ,, ,,
Urea	15·4 ,, ,, ,, ,,

DISCUSSION.

The principal interest of these cases is the high urea and glucose content of the cerebro-spinal fluid in the first three. The urea is particularly increased in the first two cases: 70 and 172 mg. per 100 c.cm. There is no reason to suppose that there was a uræmic element and in no instance was there evidence of suppression of urine. Case 3 was a straightforward case of coma following a large number of fits in a very long-standing case of epilepsy. In such a period of coma a terminal pneumonia would be a common event. In Case 2 the epilepsy was of only 18 months' duration and was characterised by periodic severe attacks of status epilepticus; a fatal termination during or following one of these attacks was to be expected. Case 1 is certainly more unusual. The pronounced loss of weight and progressive lack of interest deepening into coma, with rising temperature, pulse- and respiration-rates conform pretty closely to a series of events described by Collier [1] as status epilepticus without the fits, though in this case there was a good deal of intermittent muscle twitching, which was indicative of some active epileptic process.

The three cases in which the urea content was high all ended fatally. The fourth case had a severe status which did not end fatally, and the urea content was normal. One would infer, therefore, that a raised urea content is of grave import.

Laurès and Gascard [2] found a high urea content in cerebro-spinal fluid withdrawn by lumbar puncture immediately after a fit in six cases. Similar estimations made during inter-fit periods gave much lower figures in each of the cases. So far as we know, Laurès and Gascard's work has not been repeated. Patterson and Levi [3] found that the urea content of both blood and cerebro-spinal fluid in epileptics was within normal limits, but no mention is made of the time-relation of their estimations to fits. Goodall [4] found the nitrogen content of both blood and cerebro-spinal fluid a little raised. His cases were on a standard diet, and estimations were made two hours after seizures and during the inter-fit period, but no difference was observed in the figures obtained at these times.

The matter would appear to be one worth further investigation.

We desire to express our thanks to Dr. A. Knyvett Gordon, medical superintendent of the Virol Pathological Research Laboratories, for all the pathological reports on these cases.

A CASE OF "PERITHELIOMA" OF FASCIAL ORIGIN

WITH A DIRECT ANTECEDENT HISTORY OF TRAUMA.

BY T. VALENTINE COOPER, M.R.C.S. ENG.,

ASSISTANT PATHOLOGIST OF THE WESTMINSTER HOSPITAL ANNEXE

THE tumour in this case is interesting because of its unusual histological appearance and because of its close relationship to a previous injury.

The patient, a female, aged 58, attended hospital in September, 1929, complaining of a mass in front of her arm at the level of the elbow-joint.

History.—In May, 1929, the patient was struck by the fall of a clothes airer. A lump appeared immediately after the injury and the patient says it was about the size of a hen's egg. She was able to use the arm, but subsequently consulted a doctor on account of inability to supinate her forearm and a sensation of "pins and needles" in the forearm and hand. She was treated with hot fomentations, but as the lump and symptoms failed to disappear she came to hospital, where the casualty officer incised the mass under the impression that it was an unabsorbed hæmatoma. No fluid of any kind was found and the patient was admitted to the ward.

She was apparently a healthy woman and had not lost weight. In her left arm was a large mass, the size and shape of a pear (base downwards), situated just above and internal to the midpoint of the antecubital fossa. A small line of incision was present and appeared healthy. The mass was movable in the long axis of the limb but firmly fixed to transverse movement. Numbness and anæsthesia were present over the distribution of the ulnar nerve in the hand, and touch was only just perceptible over the median areas. There was marked wasting of the thenar, hypothenar and interosseous muscles and all finer movements of the hand were grossly limited. She had difficulty in making a fist and flexion was almost absent in two fingers on the ulnar side. No glands were discoverable in the axilla or root of the neck. Wassermann reaction negative. X ray examination showed a mass with no bony involvement.

On Nov. 28th, 1929, a piece of the mass was removed under general anæsthesia, and examined by frozen section, which showed a mass of fibrous tissue containing a number of islets of actively proliferating cells. A preliminary diagnosis of fibrosarcoma was made and the arm was therefore amputated.

The patient made a good recovery and is till now (October, 1930) without symptoms. The amputated arm was subsequently dissected out by myself, and Mr. Michael Perkins made the accompaning diagram before the parts had been separated for preservation.

The diagram (Fig. 1) is self-explanatory, but the following details must be added: 1. The biceps and triceps muscles adjacent to the tumour were densely

infiltrated by it to a depth of about 2 inches. The brachialis anticus was free. 2. The median nerve passed through the mass and the internal cutaneous nerve divided in it, but both were easily separable and

FIG. 1.

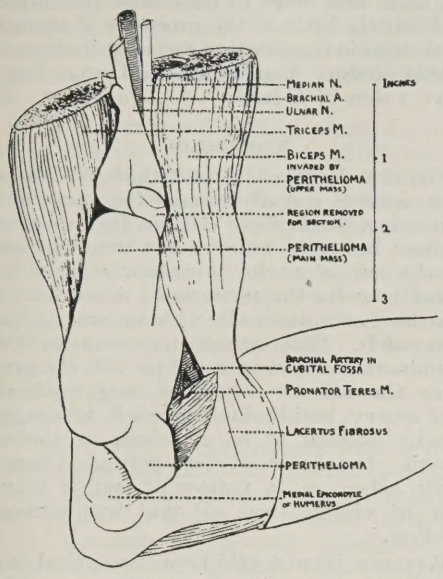

Diagram showing anatomical relationships of tumour.

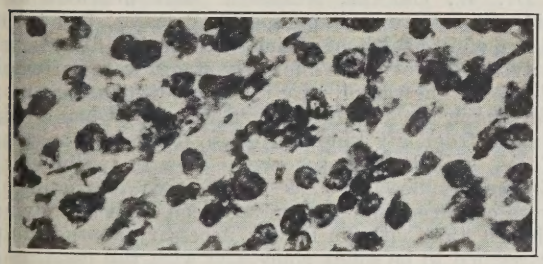
appeared only to be involved by pressure. 3. The brachial artery and venæ comites, although passing through the tumour, were freely definable on dissection. 4. The mass was readily removed from the underlying bone. From these macroscopic details it would appear that the tumour had its origin in the fascial intermuscular sheaths or septa.

HISTOLOGY.

Varying appearances are presented by adjacent sections—i.e.: 1. One section (Fig. 2) has the appearance of a round-celled sarcoma with no unusual features beyond evidence of great activity. 2. The other section is extremely interesting, for it shows the

FIG. 2.

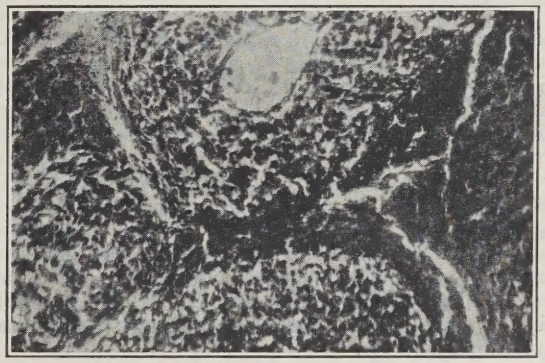


Photomicrograph (high power) showing diffuse sarcomatous area.

remarkable perivascular structure seen in Fig. 3 where the growth appears lobulated, each entity having a central blood-vessel surrounded by a wide ring of tumour cells. The vessels are more fully formed and appear to be small arteries, and the cells themselves are less embryonic in type in that they are smaller, stain better, and show fewer mitotic figures. The individual lobules are rendered obvious by their involvement by fibrous tissue and tumour debris. 3. Still another portion of this section shows masses of spindle-shaped cells and seems to be intermediate between these two previous types.

This tumour has been classified as a perithelioma in accordance with current teaching, although on further investigation it seems probable that such a classification rests on very insecure and unscientific foundations. The term "perithelioma" suggests that the condition is in some ways similar to endothelioma—i.e., to postulate "perithelioma" is first to assume perithelium.[1 2 3] Eberth[3] claimed to have demonstrated this tissue in connexion with vessels of the pia mater, but he appears to have failed to convince the sceptical that the appearances he described are not due to perivascular "lymphatics" the existence of which is well known. Roussy,[4 5] in 1911, wrote a long critical review of this subject in connexion with a tumour of the kidney. He states that in his opinion the term "perithelioma" has

FIG. 3.



Photomicrograph (low power) showing peritheliomatous arrangement.

found its way into pathological nomenclature on illegitimate grounds and without adequate investigation. He considers that tumours with such an appearance as this assume it as a result of normal anatomical structure or of peculiarity of their vascular supply, and that a peritheliomatous arrangement is secondary to other factors and not due to a primary origin from unproven perithelium. He classifies tumours of this type under three headings: 1. Cases where the appearance is solely due to normal anatomical structure—e.g., carotid body. 2. Cases due to a neoplasm of the endothelium of perivascular "lymphatics"—e.g., pia mater; for these cases he suggests the title endothelio-lymphangioma." 3. Cases where the appearance is explicable on accidental grounds and is due to hæmorrhage and necrosis emphasising certain areas of growth round the vessels.

For this last type I venture to suggest the expression "perivascular sarcoma"; although this gives a definite indication of the histological appearance, it does not produce confusion regarding the site and mode of origin.

In conclusion, I have to convey my acknowledgements and thanks to Mr. Rock Carling, under whose care the case came, and to Dr. J. A. Braxton Hicks, Director of the John Burford Carlill Laboratories, Westminster Hospital, for permission to use the pathological material.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

AT a meeting of this Section, held on Nov. 28th, with Prof. MAJOR GREENWOOD in the chair, a discussion on

Food as a Preventive of Disease

was opened by Dr. J. M. HAMILL. Well-being, he said, was dependent on two factors, heredity and environment, and of these heredity played a part which was often under-estimated. The most intimate and powerful of all environmental influences was food. By means of proper food an individual's hereditary equipment could be developed to greater advantage than by any other environmental means. The body, when properly fed and well nourished, had extraordinary powers of resistance to disease. The incidence of tuberculosis in a community appeared to be closely correlated with the food-supply, diminishing when the supply was ample, and increasing when the quantity or quality of the diet was inadequate. Troops could withstand great hardships when rations were plentiful and suited to their needs. During the Middle Ages the relationship between famine and pestilence was well understood. It was not a simple matter to say with certainty what was sufficient and suitable food, or when a diet might be regarded as completely satisfactory, but variety of the right kind would, in most cases, go a long way towards ensuring adequacy.

Inadequate diet conduced to maldevelopment and lack of resistance to disease. Specific instances were rickets, defective teeth, scurvy, beri-beri, pellagra, goitre, and a peculiar form of ophthalmia. These diseases were, moreover, only the advanced stages in a long train of disordered metabolic activity which in its earlier stages produced effects so slight as to elude all means of detection at present available. Most of these disorders resulted from deficiencies in the diet, that is, were due to negative factors, but in the production of rickets a positive factor contained in cereals might also play a part. A correct diet depended not only upon the presence of the necessary constituents, but upon their proper balance; adequacy in respect of one essential constituent might be converted into inadequacy when the balance in respect of some other constituents of the diet was altered. It was possible, however, to ensure a satisfactory diet for all practical purposes by relatively simple means if certain foods such as milk and green vegetables were prominent.

Another aspect of nutrition was the damage which might be done to important constituents of food as a result of processes which food might undergo in its preparation for consumption. An obvious example was the destruction of the antiscorbutic vitamin by drying or heating. Another instance might be the destruction of the colouring matter of flour by bleaching. This colouring matter was carotene, which would seem to be a precursor of vitamin A, and it might be that in certain circumstances the body could rely upon this carotene for an important proportion of its vitamin-A supply. The treatment of fruit by hydrogen cyanide for the destruction of insect life exerted an inimical effect upon the living cells of the fruit, and impairment of nutritive value could not be said to be excluded. Biological research tended more and more to emphasise the importance of the infinitely little in the processes of metabolism. Slight changes in composition resulting from manipulation might produce changes out of all proportion in the nutritive value of a food.

DISCUSSION.

Sir GEORGE BUCHANAN said that with regard to growing children and adolescents there was no doubt that vitamins, particularly vitamin D, were necessary and it was better to have excess than not enough; but in the case of adults on ordinary mixed diet, he wondered how far the presence of a certain amount, more or less, of a particular vitamin was an essential thing to watch. Was it vitally important to have such a discrimination of diet as would provide the particular vitamins the absence of which might conceivably produce scurvy, beri-beri, or rickets? An exaggerated importance seemed to be attached, in the case of the adult, to the need for getting vitamins in quantity, when, as a matter of fact, a very small amount of vitamin was all that was necessary to metabolism.

Sir WILLIAM HAMER said he was sceptical of a good deal of the work on vitamins until the experience of the war. That experience was very arresting. The ordinary members of the public were able in various ways to supplement the strict rations, but the people in institutions who had no such opportunities exhibited various effects of deprivation. In the big fever hospitals it had been the practice for many years to give margarine instead of butter. Ought that to be permitted?

Dr. KINGSTON BARTON said that 50 years ago rickets was regarded as due to excess of starch. All the children suffering from rickets seen in private practice in those days had been stuffed with bread, under-cooked flour, and the various patent foods of the period. Some of the physicians in those days showed that starch if boiled, cooked, or converted into dextrin could be made much less harmful for children.

Dr. W. CRAMER remarked that deficient diet did not merely produce specific diseases, but a long chain of ill-health of which the specific disease was only the last event. The early stages were extremely elusive. The reason why these conditions were more obvious in the case of children was that when a child was ill from any kind of disease it stopped growing. These specific diseases were due to pathological changes. So far as his own experiments were concerned he had never been able to convince himself that vitamin D was necessary for the adult; it seemed to be solely concerned with the ossification of bone.

Dr. THOMAS CARNWATH said that the main result of modern scientific research into matters of food had been to justify traditional practice. He recalled, in his own early days in the west of Ireland, seeing the labourers whose normal diet consisted of potatoes, butter-milk, and perhaps sometimes a little tea and pork, but they were fine strapping fellows nevertheless. When, however, they came over to help in the English harvest they were overfed with protein, and it took them a couple of months to recover. The condition of life, Dr. Carnwath added, were becoming more and

more artificial, and the question was whether the community was modifying its dietetic habits to correct the evils inherent in these changes. It was there, perhaps, that the scientific man could give assistance. It was only by careful and intensive investigation of diets that it was possible to ascertain what the food habits of different sections of the people were, and in what respect they were defective; having ascertained that, it might be possible to graft on the slight modifications necessary to bring them into conformity with scientific principles.

Dr. S. A. MONCKTON COPEMAN commented on the changes in the views on dietetics which had taken place within recent times. Was it not possible that there were one or two other factors of importance in addition to vitamins, for example, the æsthetics of nutrition? There was not the slightest doubt that if a person enjoyed his food he was all the more likely to benefit from it. Many of the diseases of adult life might be connected with the over-ingestion of vitamins, particularly of animal origin. The consumption of watercress, which contained various vitamins, was urged by Xenophon upon the Persians—another instance of the wisdom of the past.

Dr. H. C. CORRY MANN thought that in the past insufficient attention had been directed to diet in the prevention of disease. He pointed out how greatly of recent years the health of London children had improved, although the housing conditions in the London slums remained the same. Two food modifications had been responsible for this betterment—namely, the use of pasteurised milk, and the fact that there was now available a large supply of fruit, such as the orange and the apple, throughout the year. Summer diarrhœa and abdominal tuberculosis had almost disappeared. He advocated strongly the pasteurisation of milk. If pasteurisation were properly performed, scurvy would not be seen, and there would be a normal increase of growth rate. He also stressed the importance of water. He believed water to be very important because it allowed the necessary alkaline basis to be kept in suspension in the tissue fluids.

Dr. H. S. STANNUS said that in many of the so-called deficiency diseases the symptoms were positive, not negative; they were produced by the presence of something, not by the absence of something else. He was convinced that pellagra was not a deficiency disease. It was due to the action of a toxin, and was unmasked in the absence of the vitamin. The same was true, he believed, of rickets and of beri-beri.

Fleet-Surgeon W. E. HOME referred to the recent publication in Germany of some research carried out in Hamburg, where it was found that the diet of many of the working people was poor in the winter, and especially towards the end of the winter. The death-rate had two maximums, one in December and one in March. It had also been established that infectious diseases were less likely to occur in the families of people who had gardens.

Dr. J. D. ROLLESTON remarked on the absence of any authoritative information as to the vitamin content of wine and alcoholic liquors of which so much was made.

The PRESIDENT, in summing up, said that in a country like this, which was not self-supporting, and would starve on its own resources in a short while, we did not receive the food we liked, but the food we were forced to purchase through existing commercial conditions.

SECTION OF ORTHOPÆDICS.

AT a meeting of this Section held on Dec. 2nd the chair was taken by the President, Mr. P. JENNER VERRALL. Dr. L. BÖHLER spoke on the treatment in Vienna of

Fractures of the Upper Extremity.

He showed slides and cinematograph films illustrating his methods. He recommended local anæsthesia for all fractures; it was particularly valuable in compound fractures. It was sufficient to inject 20 c.cm. of 2 per cent. novocain into the hæmatoma, as this spread the anæsthetic into all the tissues. He had injected over 5000 cases and had never seen infection. The anæsthesia lasted about two hours, thus allowing for a second reduction and fixation if the first proved unsatisfactory under X rays; if necessary the injection could be repeated. Dr. Böhler also recommended Cramer's wire splinting for most cases. It formed the basis of the "aeroplane" splint for fracture of the middle third of the humerus. This was very difficult to fix, but when it was properly fixed the patient was free from pain and could wear it for six or eight weeks. It could not be applied satisfactorily under general anæsthesia. After two weeks the patient could use his hand and forearm and even move his shoulder muscles, while still on the splint, and after ten weeks recovery would be complete.

Fractures of the lower third of the humerus showed angulation and overlap. If the overlap was not reduced by traction there was a risk of nipping the brachial artery between the upper fragment and the coronoid process. Supination always increased the angulation, and the result might be musculo-spiral palsy, but pronation corrected it. The arm was therefore put up in plaster in right-angled flexion and pronation, and then fixed in an aeroplane splint with an extension device. After ten weeks all joints would be free and the muscles strong. The aeroplane splint was also the best application for fracture of the neck of the scapula.

For fracture of the clavicle he used an apparatus which held the arm away from the chest by an axillary pad, but did not press the elbow to the chest—a practice which brought a danger of pressure on vessels or nerves. This apparatus left the arm quite free, and overcame the difficulty of keeping the fragments reduced while healing took place. Recovery was complete in four weeks. If there was a recalcitrant middle fragment a secondary shoulder strap could be used to hold it in place. Even fracture-dislocation of the shoulder-joint should be treated by closed methods. Dr. Böhler demonstrated how the head could be reduced by alternate lateral pulling and upward pushing; the arm was then treated on an aeroplane splint with extension.

In myositis ossificans it was important, he said, not to operate too early, and the bone must be removed together with its periosteum.

THE FOREARM AND HAND.

For the reduction of severe forearm fractures, with both bones broken and displaced, the brachial plexus should be injected with novocain. Counter-extension was obtained by passing a loop of webbing round the upper arm, blocking the loop open to prevent pressure on the limb, and fastening its ends to the wall or door-handle. The fingers were then painted with mastisol and covered with a light gauze bandage. On this an assistant took his grip and exerted a very strong slow pull. When reduction was effected

rustless wire was drilled through both bones at their upper and lower ends—still under traction—and the arm was put up in plaster, flexed and pronated. Small volar and dorsal rods were placed in the interosseous space, and after the application of the circular bandage these were pressed home. Small lock screws in the plaster held the wires, and the arm was put on an aeroplane splint for two or three days to prevent circulatory disturbances. In more than 40 cases Dr. Böhler had seen no infection; he also used this wire-drilling method for complicated fractures of the carpus and lower end of the forearm. It was important to remember, he said, that bony union never occurred, in complete transverse fractures with displacement, in less than eight weeks. His method of treating pseudarthrosis was by drilling grooves at the ends of the bones; it differed from the similar process described in the *British Journal of Surgery* in 1914 in that the drilling was usually done subcutaneously.

For difficult fractures of the lower end of the radius a similar method was used; it was very important that the assistant should maintain continuous traction while the fixation was applied, and that he should have something against which to brace his foot so that it did not slip. For simple Colles's fracture only gauze bandaging and a splint were used. Active movements began as soon as the cast was set, even after very severe injuries; patients could dress themselves, make their beds, knit, and cook three days after the injury, and these natural activities had great therapeutic value. Two weeks after removal of the splint recovery should be perfect.

A fracture of the little finger (first phalanx) was put up in a U-shaped wire splint fastened to the wrist by plaster; the finger was attached to the wire in hyperextension by adhesive strapping, and the fracture reduced by gradual bending of the wire. Fractures of the scaphoid always united if properly fixed for an adequate period—six weeks. These injuries were seldom fixed for sufficient periods. Often the central fragment was deprived of its circulation by the fracture, and the re-establishment of its blood supply sometimes demanded months of fixation, but the patient could go on working during this time if his hand was in plaster in slight dorsiflexion. Every time he closed his fingers he axially compressed the scaphoid, which helped the treatment. Dr. Böhler never removed the scaphoid, as the function of the hand did not seem to be much improved by operation. Dislocation of the semilunar bone could be reduced by strong traction in recent cases, but older cases could be treated in an extension apparatus with pins through forearm and metacarpus. In these old cases the gap which the semilunar should occupy closed up and must be re-opened. Similar methods were applied to other dislocations round the wrist. Compound fractures of the fingers were treated by closure of the skin only and a wire extension on the uncovered finger; exposure to air prevented maceration and infection, the serum and blood forming a dry crust which protected the skin. If a dressing were put on the serum and blood soaked it, infection followed.

DISCUSSION.

Mr. E. G. SLESINGER mentioned the heavily-infected compound fracture when it came too late for primary suture. He had found in Gallipoli that the more maggots there were in a wound the better the end result, and that Dakin's solution dissolved protein. Nature's method was to supply maggots to eat the dead tissue, and the deliberate use of her method had given good results. After four days the maggots could be gently scraped away from a clea granulating wound.

Mr. C. H. BROOMHEAD said that teamwork wa the secret of Dr. Böhler's success, and we had much t learn from him. The position he used for fracture of the humerus was a great advance. He asked hov to treat separated epiphysis. He thought the menta state of the patient covered with maggots wa regrettable. Dr. Böhler had not a masseur in hi clinic; often the injudicious masseur did more harn than good. The patient was the best indicator of th movements suitable for him.

Mr. J. P. HOSFORD said that what had mos impressed him in Dr. Böhler's clinic was the absenc of general anæsthesia and of massage. He had see remarkable results with local anæsthesia. Earl movement saved subsequent stiffness, but was onl possible with a perfectly fitting splint. He had give up massage for fractures of the upper end of th humerus and lower end of the radius, allowing th patient to move about in a plaster cast. It wa remarkable what good movements could be obtained

Mr. MCCRAE AITKIN regretted the absence of Si Robert Jones, who had long ago preached length an continuity of treatment. As Dr. Böhler had said true principles never changed, but each man mad his own technique.

Mr. G. R. GIRDLESTONE asked if the hairs came o with the plaster.

Mr. W. H. OGILVIE asked how long after th fracture local anæsthesia was possible, and how th plaster was removed.

Dr. BÖHLER, in reply, said that wounds could onl be closed within the first six hours after fracture The great feature of treatment was uninterrupte rest. He had had the same experience with maggots and had seen wonderful results from their use i osteomyelitis in childhood. Reduction of th epiphysis was not difficult, but traction must be com bined with bending movement. Simple local anæs thesia could be used as long as there was a hæmatoma sometimes as long as two weeks after injury, bu when the hæmatoma had gone infiltration could b used. He never shaved or anointed the skin, becaus the hairs gave the plaster good fixation and did no hurt when they were all pulled on together. Whe it was removed four or six weeks later new hairs ha grown and were therefore not incorporated in the cas

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of this Institution on Nov. 20th Dr L. J. PICTON read a paper on

Amylaceous Dyspepsia.

In this condition, he said, dyspepsia was noticed t follow starchy meals. A starch-eating habit wa recognised, and cure followed abandonment of th habit. The form of starch was important; unburs granules, such as those in the gluten framework o the bread sponge, were insusceptible to the influenc of ptyalin. Slimy gastritis might be caused by exces sive, especially unburst, starch as well as by infectiv catarrh. Delay might be caused not only by slim gastritis, but also, normally, by eating starch an meat together (Pavlov) as in the conventional dietary The satiety necessary for the tranquility of th stomach could be achieved by taking meat an greens. An equal filling of starch and meat involve unnecessary digestive labours as well as delay, bu

greens passed quickly (Beaumont, 1833). Ptyalin digestion in the mouth and stomach "hopper" might start the cycle of digestive preparation. Dr. Picton described a peristaltic and metabolic "gradient" (Alvarez), and discussed the site of its pacemaker. He suggested that the pacemaker could be inhibited by sensitisation and toxic influences—e.g., excess of starch. Symptoms were due to delay, constipation, and peristalsis in the wrong direction to an abnormal degree through flattening or reversal of the gradient. He advocated starch at one meal, meat and greens at another, in dyspepsia.

Ramisection for Hirschsprung's Disease.

Mr. J. B. OLDHAM reported two cases of Hirschsprung's disease on which lumbar sympathetic ganglionectomy and ramisection had been performed two years ago with excellent results. In the first case a girl, aged 4, whose bowels were only opened every 3–14 days in spite of prolonged medical treatment, had the left second, third, and fourth lumbar ganglia, with their rami and the intervening cord, removed, and since then the bowels had acted daily without the aid of drugs. The second patient had been attending hospital regularly for 11 years. Her bowels acted very irregularly. She frequently had to be admitted to hospital with attacks of acute obstruction. On many occasions fæcoliths 4–7 inches in diameter had to be removed, and she had undergone colotomy, coloplication, colostomy, enteroanastomosis, and partial colectomy, but the condition always recurred. After bilateral lumbar sympathetic ganglionectomy and ramisection the bowels had continued to move regularly every day without the aid of drugs or diet. Mr. Oldham described the technique of the abdominal approach to the sympathetic chain, and recommended spinal anæsthesia. He also gave an account of the varying forms of surgical and medical treatment that had been tried from time to time and the unsatisfactory results they had produced. The similarity between Hirschsprung's disease, cardiospasm, congenital pyloric stenosis, and hypertrophic ileal obstruction was described, together with the physiological basis for the hypothesis that all these conditions were due to a hyperactivity, real or comparative, of the sympathetic nervous system. Mr. Oldham suggested that the excellent results obtained by sympathectomy in Hirschsprung's disease gave proof of the truth of this hypothesis.

Dr. C. ALLAN BIRCH said he was interested in lumbar sympathetic ganglionectomy for peripheral vascular diseases, and asked whether this operation ever produced any effect on previously normal bowel movements.

Dr. NORMAN CAPON remarked that earlier diagnosis of the condition was desirable, and pointed out that in the young baby abdominal distension was by no means invariable. It was noteworthy that at least one case had been reported in which severe vomiting and constipation had led to a mistaken diagnosis of congenital pyloric stenosis.

Mr. PHILIP HAWE said that it seemed clear that sympathetic resection should have much more chance of success in conditions such as dilatation of the colon, in which sympathetic hypertonia was probably to blame, than in the treatment of spastic paralysis where the underlying physiological principles were far from clear. There was some reason to expect that this operation would be extended to conditions of intestinal disorder other than Hirschsprung's disease. He had been associated with Mr. K. W. Monsarrat in a case of advanced colonic stasis which resisted medical treatment for years but responded in a most convincing way to a lumbar sympathetic ramisection.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A MEETING of this Section was held on Nov. 14th, with Dr. H. F. MOORE, the President, in the chair.

Diabetes with Phthisis.

Dr. JOHN LAIT showed a case of diabetes mellitus complicated by phthisis, and read a note on the condition.

The patient, a girl aged 14, had apparently suffered from untreated diabetes for over six months before entering hospital. Soon after admission she developed pyrexia and a cough. Radiographic examination showed early cavitation of the left lung in two places, and the sputum contained tubercle bacilli. She had an acute and rapidly progressive tuberculosis, and the general condition was becoming gradually worse in spite of careful treatment of the diabetes. Dr. Lait induced artificial pneumothorax on the affected side, and though at first, owing to adhesions, he did not get complete collapse, the child at once began to improve. The pyrexia stopped, the cough and sputum disappeared, and the weight began to increase.

In order to collapse the lung, said Dr. Lait, he had found it necessary to use a high pressure of air in the pleural cavity so as to stretch the recently formed adhesions. In this he was almost completely successful, for the child stood these high pressures (about 20 cm. water) extremely well, and now (about five months after induction) the left lung was almost completely collapsed. Recently a small pleural effusion had appeared on the collapsed side; this did not seem to do any harm or occasion any discomfort, and might possibly be looked on as assisting the treatment. The diabetic status was excellent, the patient's weight being steadily on the increase.

The PRESIDENT said that in 1914, when Allen was working out the dietetic treatment of diabetes, Joslin noticed that in diabetic patients who developed tuberculosis and lost weight the diabetes improved, and there was sometimes a great increase of the glucose tolerance.

Dr. E. T. FREEMAN, referring to artificial pneumothorax, said that it was remarkable to find a patient as young as Dr. Lait's standing such a high pressure especially on the left side. It was very unusual to get such a high pressure without any movement of the mediastinum. He thought that if the effusion could be increased in size and brought up to the level of the cavity in the lung, it would be a great safeguard against rupture of the cavity. If it was intended to maintain the pressure, yet avoid rupture, it would be better to withdraw fluid and put in air.

Treatment of Polycythæmia Vera Rubra.

Dr. CYRIL MURPHY showed and described the following case:—

A man, aged 51, a cooper, complained at various times since April 1922, of inflammation of joints, and latterly of pain in the left upper portion of his abdomen; also of headache, lightness of the head, and vomiting on one occasion. Late in 1923 Dr. Murphy examined him, and found that the lips, the lobes of ears, and the finger-tips were cerise-coloured and the cornea purplish. The venules of the face seemed engorged—a feature still noticeable. The spleen extended four fingers' breadth below the left costal margin, and was very tender. The left knee subsequently became swollen in a spindle-shape, while the veins of the leg stood out in relief, and flush over the left knee became almost cyanotic. He was intensely feverish for about 14 days, and

the fever was not influenced by salicylates. Other joints, particularly of the great toes and wrists, were subsequently involved and were just as resistant to treatment. The arthritis was now the most absorbing symptom.

Subsequent examination of the blood showed a negative Wassermann reaction, and a red cell count of over 11 millions per c.mm. Later counts were (1925) 9 millions, with 30,000 leucocytes, and (1927) 8 millions with hæmoglobin 125 per cent.

Many methods of treatment were tried, chief among them benzol, and various anodynes which were of no value. Later, sodium carbonate was given in 10-grain doses three times a day in an attempt to diminish the acidity of the blood, which some members of the French school at this time thought was increased in this condition. This treatment seemed to give some relief, and in the course of a year lowered the blood count by one million. X rays to the long bones seemed to aggravate the symptoms, so this form of treatment was early discarded. Venesection, too, was abandoned as being of very temporary benefit.

Since seeing a number of cases of Vaquez's disease treated at the Mayo Clinic by ingestion of phenylhydrazine hydrochloride, Dr. Murphy had used this drug in the present case, he said, for 13 months, during which the patient took 0·1 g. per week. The spleen was still enlarged and tender, and there was still—though to a very slight extent—some of the characteristic cerise hue noticeable on the lips. The blood pressure, which had been 168 systolic and 97 diastolic, was now 142 systolic and 81 diastolic. The blood count was: red cells 4,500,000; white cells 13,200; hæmoglobin 80 per cent., and colour-index 0·9.

The PRESIDENT said he had not previously known that there was any connexion between arthritis and polycythæmia. He had treated four cases of this disease in the last three years, one woman and three men. They all had splenomegaly and albuminuria, and the typical facies, cerise in colour. The woman, aged 48, was treated with X rays applied to the bones, but with very little benefit. Phenylhydrazine was tried, and reduced the red blood cell count and the hæmoglobin, and it was found that 0·1 g. of the drug daily was sufficient to keep the blood normal. One man, aged 42, was given phenylhydrazine, but with very little result. Next a course of X rays was tried, also with little result, and then the phenylhydrazine was tried again. After about four weeks' treatment he began to improve, and it was now found that 0·1 g. every 7 to 10 days was enough to keep the blood approximately normal. The second man, aged 44, had apparently had an attack of thrombo-angiitis obliterans in the left radial artery. This condition had been described as a complication of polycythæmia, but was supposed to be very rare. This patient had a course of X ray treatment for three months, but the result, as far as the blood was concerned, was absolutely negative. He was now having phenylhydrazine, and was improving. The fourth patient, a man aged 55, had had phenylhydrazine for two months, but with no result. He was now having X ray treatment. Dr. Moore thought that in these cases X rays made the bone-marrow more vulnerable to the action of phenylhydrazine.

Dr. MURPHY, replying, said he thought there must be some connexion between polycythæmia and arthritis, for in his case the arthritis improved when the polycythæmia improved.

Diagnosis of Renal Rickets.

Sir WILLIAM WHEELER read notes on two cases suggestive of renal rickets, and showed one patient. The condition, said Sir William, comprised: (1) early renal derangement; (2) infantilism or dwarfism which might be early or only at puberty; and (3) rachitic changes in the bones, generally of the type of adolescent rickets.

In his first case renal rickets was suspected in a chil aged 7 owing to the presence of albumin, red blood cell and casts in the urine, combined with polyuria. Ther were rachitic changes in the chest and cessation of growth The child had blue sclerotics, a condition not associate with rickets. Radiographic appearances of the bones wer not suggestive of the renal type of rickets, and finally bloo examination, reported by Dr. A. G. Thompson, was agains the diagnosis. The Wassermann reaction was strongl positive and congenital syphilis probably explained all th phenomena. The albuminuria was intermittent or temporary for it was not found at a later date.

In the second case the patient suffered from doubl congenital hydronephrosis. Tests were made with intravenou injections of uroselectan. There was a stone in the le kidney. The stone was removed and the kidney was foun atrophied and cystic with a dilated pelvis. The radiologist' report stated that there was pronounced dilatation of th pelvis and calices on the right side, with moderate dilatatio on the left which contained the stone. The child had under gone five operations for rachitic deformities.

In this case, said Sir William, the radiographi appearances of the bones approximated to th description of renal rickets given by various writer After removal of the stone albumin disappeare from the urine but reappeared after an interva The patient was aged 17, but was only 4 ft. 3 in. i height—no taller than an average child of ten The prognosis of renal rickets was bad. Antirachiti treatment—e.g., by sunlight and cod-liver oil—wa believed by some authorities to precipitate uræmia Most of the cases recorded had come from Englis industrial areas.

Dr. A. G. THOMPSON said that four clinical types o rickets, could be distinguished—namely, ordinary infantile rickets, late rickets, and two peculiar type associated with cœliac disease and with rena infantilism. Nearly 90 per cent. of the inorgani matter of the bones of young children consists o tri-calcium phosphate, and if calcium and phosphoru were supplied in adequate amount in the diet goo bone was laid down. In infantile rickets there wa a negative balance of these elements, as much bein excreted as was absorbed. In addition, the bloo phosphorus was very low (1–2 mg. per cent.), thoug the calcium was usually normal. Hence there was a upset of the calcium phosphorus ratio with con sequent failure of ossification. This might resul from several factors—e.g., faulty diet, lack of vitamin D and sunshine, and bad hygienic conditions. I renal infantilism, though the conditions might b perfect, a peculiar type of rickets often developed This was due to retention of phosphorus by th damaged kidney with consequent upset of the calcium phosphorus ratio. Dr. Thompson did not think either of Sir William's cases was renal rickets, though both were interesting and obscure examples o infantilism. The first was probably mainly syphilitic with perhaps a rickety element added. The second might be a case of healed rickets.

Dr. R. E. STEEN said that ordinary rickets was common, late or adolescent rickets was rare, and renal rickets was extremely rare. He mentioned a case of renal rickets which he had seen in Great Ormond-street Hospital, and said that the thing which struck him about it was the marked arterio-sclerosis of the vessels. The blood-urea was high, and the blood pressure also was raised.

DERBYSHIRE ROYAL INFIRMARY.—The 121st annual report shows that 6370 patients were admitted during the year; out-patients numbered 13,000, and casualties 14,148—substantial increases in each category. In-patients stayed on an average 17·6 days. There was an increase of more than 16,000 out-patient attendances, the total being just under 176,000. Since 1914 the number of beds has increased from 240 to 346. The income was £51,012 and the expenditure £50,989.

REVIEWS AND NOTICES OF BOOKS

Tuberculosis among Children.

By J. ARTHUR MYERS, Ph.D., M.D., F.A.C.P., Chief of Medical Staff, Leymanhurst School for Tuberculous Children; Associate Professor of Preventive Medicine, University of Minnesota. With chapters by C. A. STEWART, M.D., Ph.D., Assistant Professor of Pediatics at the University; and PAUL W. GIESSLER, M.D., Assistant Professor of Surgery at the University. London: Baillière, Tindall and Cox. 1930. Pp. 208. 16*s*.

THE first part of this book deals with tuberculosis n infancy. Congenital tuberculosis is practically nknown, and the author remarks that tuberculous nfection in infancy always results from contact with a erson or animal suffering from tuberculosis or acting s a carrier. A higher incidence of disease exists mong infants with prolonged exposure to infection, nd this incidence is found to vary directly with the pportunities for exposure. A positive intradermal uberculin test indicates that the child has been nfected, whereas a negative one is strong evidence nat it has not. The positive test indicates allergy hich appears to ebb and flow with the activity or tency of a tuberculous lesion. The author points ut that physical signs are usually of no avail and nat X ray examination combined with symptoms nd history of the case are the most important guides diagnosis. It is refreshing to read that the prognosis f tuberculosis among infants usually is very good. hildren undoubtedly have an excellent resistance to uberculous infection in spite of the old-fashioned aching that the disease in childhood is always fatal. n the section dealing with prevention it is stated nat the first step is to prevent exposure. If infection as already taken place one should guard against rther infection.

In the second part of the book tuberculosis in ildhood is discussed, whilst the third part is devoted tuberculosis in the "teens." There is an interesting apter on chronic non-tuberculous basal pulmonary sease and another on tuberculosis of the bones, joints, d other sites besides the lungs. At the end of ch chapter is an excellent summary, and a full list references to other authors is included. In an troductory chapter Dr. Allen K. Krause pays ibute to a book which will be of value to all those ho are interested in the problem of tuberculosis.

he Diagnosis of Mental Deficiency.

By HENRY HERD, M.A., M.B., Ch.B. Edin., Senior Assistant School Medical Officer, Manchester Education Committee. London: Hodder and Stoughton, Ltd. 1930. Pp. 272. 12*s*. 6*d*.

THIS wise and practical handbook should be in e possession of every school medical officer and acher, and will be welcomed by all who have to deal th mental defect. Dr. Herd begins by discussing e legal definitions and social implications of mental fect, and then threads his way with a sure step rough the difficult maze of psychology and mental velopment. Without going into technicalities he ntrives to explain the light thrown on the subject by ychological conceptions, and to give a general working sis of psychological principles for the student of ntal defect. He then goes on to the diagnosis oper, indicating the points which must be obtained from the patient himself and from other people, and finally discussing the various tests, from the Binet-Simon scale and Porteous mazes to temperamental and scholastic tests. His ninth chapter gives a clear outline of the grades of deficiency, and is followed by 24 illustrative cases (which, by a curious misprint, are called "illustrated cases" at the head of each page). His chapter on moral defect discusses this thorny question with common sense, and the remaining chapters deal with legal duties and powers, preliminary selection and treatment, and future developments. Each chapter is supplied with a short bibliography which will enable the interested reader to pursue the subject in greater detail than the scope of this work allows, and an appendix includes forms of report and certificate. The book is attractively produced and pleasantly written. It is illustrated with photographs of half a dozen typical defectives, and a number of drawings by normal and defective children. Dr. Herd is to be congratulated on his success in the task he set himself: "to provide a book midway between the medical and psychological, containing sufficient material from both aspects for the examiner." The Binet-Simon tests are not given in sufficient detail to enable a person who is not familiar with them to use them straight out of this book; but that is a wise precaution, for mental testing should never be learnt exclusively from a book, and the shortened form given here provides a useful reminder for those who are not using the tests every day but have learned how to apply them.

Simple Beginnings in the Training of Mentally Defective Children.

Third (Memorial) edition. By MARGARET MACDOWALL. London: Law and Local Government Publications, Ltd. 1930. Pp. 133. 3*s*. 6*d*.

THE publication of a third edition of Margaret Macdowall's little book on the training of mentally defective children is a fitting memorial of her pioneer work in this special and—at the time of its first issue—little regarded department of education. For her work, of which this book is the record, was her life—no mere occupation in the ordinary sense, but a real vocation to which she felt herself called. Her realisation of her vocation came somewhat suddenly through the presence of an imbecile child in the family with whom she was living, and she gave herself wholeheartedly henceforth to the discovery of methods of training such children and to their practical application. For a time she worked under the guidance of Dr. Shuttleworth at the Royal Albert Institution at Lancaster, and later started a small school at Ealing which ultimately developed into the school at Burgess Hill in Sussex. As is emphasised by both Sir Maurice Craig and Dr. A. F. Tredgold in the introduction to this memorial edition, the keynote to the success of her work was the fact that she made a special study of each child, got into intimate touch with its special abilities and disabilities and its special traits of character, and adapted her training to the individuality she so discovered. Intuitive insight there must have been and was, but it was reinforced by careful observation and thought. Public authorities sent students to study her methods, and thus her ideas and ideals were spread abroad and have become common knowledge to those interested. An integral part of her work was its religious aspect, for it was an essential

tenet of the society under whose auspices she worked that the spiritual side of man's nature must be cultivated as a means to the development of his mental powers, and this belief coloured all her efforts.

The methods of training described in the book are obviously applicable to quite low grades of deficiency, at least as low as the imbecile. Much stress is laid upon detailed method in the training in such elementary acquirements as eating, dressing, sitting, walking, talking, control of even simple movements, muscular balance, cleanly habits, and the conquest of bad automatic habits, such as body rocking and nail-biting. Lessons in simple domestic and industrial processes are given in much detail—a point that makes the book of special value for young and inexperienced teachers and for intelligent parents. The book reveals an intimate knowledge of the special characteristics of mentally defective children, and of the many difficulties that arise in their education. Much of her teaching has become accepted tradition now, but no special school teacher can afford to miss reading it, and even certifying officers will learn much from a careful perusal of its pages. At times her enthusiastic optimism carries her beyond the facts. Of the spastic paralytic type, for example, she remarks that "in most of these cases the ideas are there and also the desire to express them," and that the only obstacle is the "lack of control of muscular energy." Yet one has to recognise that without the idealism which saw visions in advance of possibilities, she would not have done the work she did. The whole book and her whole life is a useful reminder of the necessity for a sympathetic idealism in the training, not only of mental defectives, but also of the many other types of cripples, physical or mental, for whom this humanitarian age loves to provide.

Manual of Physiology

for Students and Practitioners.

Third edition. By H. WILLOUGHBY LYLE, M.D., B.S. Lond., F.R.C.S. Eng.; and DAVID DE SOUZA, M.D., D.Sc., F.R.C.P. Lond. London: Humphrey Milford, Oxford University Press. 1930. Pp. 820. 16*s*.

PRESENT-DAY students of physiology are not a little embarrassed with the array of text-books from which they have to make a choice. The authors of the volume under review have endeavoured to compromise between the classical tome and the ubiquitous "cram" book, and to give their readers a general survey of the subject that is neither too detailed nor unduly condensed. About 40 pages are devoted to chemical physiology, and good use has been made of this space. There follow the usual sections dealing with the different systems and functions of the body. The authors deal cautiously with debatable subjects, and where more than one hypothesis is applicable they endeavour to state the position impartially. A very useful chapter is devoted to diet and food values; and the section dealing with mental physiology gives a good introduction to this branch of the science. The section on sense organs is well presented, especially the portion which explains vision. The eye and its appendages are discussed very fully both from their anatomical and their physiological aspects; this part of the book, comprising fully 60 pages, forms almost a treatise in itself. The authors state that they have endeavoured to indicate the bearing of physiology upon medicine and surgery, but they have obviously been hampered in this design by limitations of space. Nevertheless the busy practitioner will find this volume very useful for revising his knowledge of physiology. There are very few errors of commission, but one can scarcely agree with the inference to be derived from the authors' definition of defibrinated blood that it is composed only of blood serum with oxyhæmoglobin in solution. An illustration is given on page 382 to show the effect of respiration upon the blood pressure. The curve indicates 17 heart beats for one respiratory phase; this can scarcely be looked upon as being physiological. The book bears evidence of having been brought into line with the more important recent advances, although the omission of all reference to Collip's work on the parathyroids is surprising. The volume is well printed and of convenient size.

Clinical Chemistry in Practical Medicine.

By C. P. STEWARD, M.Sc., Ph.D., Lecturer in Biochemistry, University of Edinburgh; and D. M. DUNLOP, B.A., M.D., M.R.C.P., Assistant in Department of Therapeutics, University of Edinburgh. Edinburgh: E. and S. Livingstone. 1930. Pp. 246. 7*s*. 6*d*.

OF recent years several books on clinical biochemistry have been written, and it becomes increasingly difficult to determine which book is suitable for a particular class of worker. The authors have intended this publication to be for the use of the practitioner, the house physician, and the senior student; as they themselves say, "it is not an elaborate text-book of biochemistry for the laboratory worker." The methods for estimating blood constituents, with the exception of urea, are not given in detail, but the interpretation of their results is fully explained. The chapter dealing with gastric analysis is disappointing in view of recent work, and no mention is made of the blood plasma proteins. It is a useful book in many respects, but perhaps too much has been sacrificed for the sake of simplicity and brevity.

Diseases of the Genito-Urinary System

in Infancy and Childhood.

By HENRY F. HELMHOLZ, M.D., Professor of Pediatrics, University of Minnesota (the Mayo Foundation); and SAMUEL AMBERG, M.D., Associate Professor of Pediatrics at the University. Supervising Editor: ROYAL STORRS HAYNES, Ph.B., M.D. London: D. Appleton and Co. 1930. Pp. 239.

THIS book forms Vol. XIX. of the Clinical Pediatrics series and is only obtainable with Vol. XX. on Laboratory Pediatrics and Vol. XXI., which contains the composite index and cumulative Supplement at 32*s*. for the three volumes. Vol. XIX. is an account of the genito-urinary diseases as they occur in early life. It comes from the Mayo Clinic, and carries on the tradition of excellent workmanship and full reference which we are accustomed to look for in any publication emanating from this clinic. It does not bring forward anything very new, but should prove acceptable to the "general practitioner of medicine" for whom it is intended. The volume contains a series of monographs with illustrative cases, the longest sections being those devoted to the pyogenic infections and to bilateral hæmatogenous renal disease. Enuresis and its treatment are also discussed in full detail. Sections on embryology and methods of diagnosis are included, and the authors give some very useful tables of diet for children of varying ages.

THE LANCET.

LONDON: SATURDAY, DECEMBER 6, 1930.

THE SIGNIFICANCE OF FALSE WITNESS.

THE Maudsley Lecture, delivered by Mr. Justice MCCARDIE before the Royal Medico-Psychological Association on Nov. 20th, has received attention from the press and called forth a question in Parliament. Handled by one whose task for years has been to extract from specific tangles a specific answer to the problem of what really happened, the subject of "Truth" made a wide appeal, and the lecturer's definition of truth as 'conformity to fact and reality" seems straightforward enough to be accepted by everyone. But recent philosophical conceptions have made unstable some of our beliefs in fact and reality; illusion, misinterpretation, and imperfect observation have been subjects of laboratory experiment, and the part they play in affecting those beliefs and in vitiating evidence is becoming better known. Instead of being a common gift of mankind, the power of accurate observation and description is so rare that its possessor stands out above his fellows, and the deliberate cultivation of such power is a first essential in scientific training. We are confused, too, by the ascription to truth of two different qualities—accuracy and honesty; besides measuring it by the objective standard of reality we apply to it a subjective standard of morality. "Mistaken but honest" as applied to a witness expresses these two standards, and the common situation thus summed up is scarcely covered by Sir HENRY MCCARDIE'S list of the three major enemies of truth—lack of courage, self-interest, and bias—unless we take bias in a very general sense. He noted that the psychology of bias had yet to be fully revealed, and asked whether we perceived the foes of truth who might be lurking in our own minds and instincts. The psychologist might answer that bias in all its forms, especially bias due to unconscious mental processes, has been the special study of psychology; indeed, it is laid to the psychologist's charge that by his emphasis upon unconscious bias he has dethroned reason and undermined personal responsibility.

A superficial or naked-eye psychology suffices for the understanding of a great deal of false witness, such as that form of perjury so common since permission to give evidence has practically compelled the accused to enter the box. False witness due to our weak powers of observation, or to the partisanship inseparable from our methods of legal advocacy, is less obvious though easily recognised when its mechanisms are borne in mind. There is other false witness in which a naked-eye psychology goes woefully astray, as in the case commented upon in our columns some weeks ago[1] in which a youth made against himself a false accusation of murder, was released as a mischievous liar, and subsequently confirmed the suspicion of mental disorder by attempting arson. The problem of motive in such cases can be solved only by a technique of mental exploration, and the same method is called for in some of the cases referred to by Sir HENRY MCCARDIE in which children or girls gave false evidence against men charged with sexual offences. Here the corroboration of false evidence sometimes suggests folie à deux. Short of such extreme cases there are certainly others where the source of the impulse to testify falsely is recognised dimly or not at all by the witness and in which the facile explanation of hard lying is inadequate. Sir HENRY expressed a hope that psychologists would give attention to the problem of truth-finding in open court; but the open court gives little opportunity for direct psychological aid in that respect, and anything but open methods is against the spirit of our law. The word-association test, for example, would be rejected as savouring of the so-called third degree. Naked-eye psychology must at present suffice to sort out facts from a tangle of evidence, and whoever has sat for an hour or two in a Metropolitan police-court must admire the skill of an experienced magistrate in performing his task. Yet the cases are common in which deeper knowledge can reveal the significance of evidence or conduct that would otherwise escape attention and can aid in a fuller understanding both of the evidence and the facts. Mr. Justice EVE took the occasion of the anniversary dinner of the Royal Society, on Dec. 1st, to dissociate himself from his learned brother's view as to the increase of perjury in law courts, but the divergence of opinion may well be explained by the fact that the dissentients were not agreed upon definitions.

PHYSICS AND PHYSIC.

BY the beneficence of Mr. ELDRIDGE R. JOHNSON an institute for medical physics has been founded in the medical school of the University of Pennsylvania. Its object is not, as might be supposed, to exploit the methods and results of massage, hydrotherapy, gymnastics, radiation treatment, and the like, but to see how far modern experimental philosophy can aid in the understanding of life and disease. The purpose of the Foundation is to interpret pathological and normal biological phenomena in terms of physics, and to investigate them along physical lines; it is also anticipated that considerable use will be found in having a body of trained physicists available to solve specific physical problems with which the clinician meets in the wards or in his research. All this is, we believe, quite a fresh departure in a medical school, and raises many interesting considerations, some of which are dealt with in a stimulating address[2] given by Prof. A. V. HILL at the inauguration

[1] THE LANCET, Oct. 11th, p. 810.
[2] Jour. Amer. Med. Assoc., Nov. 8th, p. 1393.

ceremony. On one point Prof. HILL is explicitly clear; he does not believe that the phenomena of life can be explained in terms of the physics and chemistry of to-day. What the future will produce, no one can tell. But for the present he insists that in the organism as a whole we have a phenomenon of a special kind, whose unity and uniqueness are as essential as any of the concepts of physics. He sees, however, that there are considerable difficulties in subjecting the organism as a whole to experimental analysis, and he urged upon his audience the notion that the best way of investigating the organism is the way provided by the ideas and technique of physics. No one will doubt the universal value of precise measurement in all branches of natural science, and his own distinguished contributions to knowledge are sufficient evidence in favour of Prof. HILL'S thesis that physics is at least one of several good methods of examining live organisms, so long as the examiner is a real physicist and not a physicist ad hoc.

All engaged in scientific pursuits will support the proposal that work should be encouraged in the fields that lie between the main territories into which science is arbitrarily divided. The increasing mass of knowledge makes it impossible for any one mind to include the whole; it is becoming increasingly difficult for anyone to be acquainted with the whole of one department. Most workers perforce keep within some limited field. And yet there must be continual overlap if the best results are to be obtained, and there are evidently considerable advantages to be looked for if occasionally the chemist will become a bacteriologist or the zoologist a morbid anatomist or, as in the present instance, a physicist an applied physiologist. Prof. HILL also draws attention to one curiosity of university education which must surely considerably hamper this transference and coöperation. Every student of biology is compelled to acquire some elementary knowledge of chemistry and physics. But students whose main interest is in chemistry and physics are allowed to go through their whole curriculum with nothing else than mathematics; this course may produce excellent physicists, but it leads to a sadly uneducated view of the real world and to an amazing ignorance of what biology is about. Surely it would be to everyone's good that an elementary acquaintance with biology should be demanded of every serious student of natural science. Advances in physiology and medicine may come from anywhere; they have, in fact, come from the most unexpected sources, and we believe with Prof. HILL that almost any sort of curiosity has its clinical contribution to make—perhaps even spiritualism, of which he seems to think poorly.

THE DENTIST'S SIGN.

ESTABLISHED for the statutory purposes of the Dentists Acts and therefore charged with the duty of upholding the status and standards of a learned profession, the Dental Board of the United Kingdom continues its efforts against advertising by dentists. In particular it seeks to suppress the abuse of signs announcing a dentist's place of practice. The "Important Notice," circulated to all practitioners, informs them clearly that the only permissible sign is that which "in its character, position, size and wording is merely such as may reasonably be required to indicate to persons seeking them the exact location of and entrance to the premises at which the dental practice is carried on." The Dental Board has wisely restricted itself to this general statement of principle and has not undertaken to delimit with a yardstick the uniform dimensions permissible to announcements and lettering. Naturally the general standard cannot be applied to particular cases without apparently evolving certain rule-of-thumb formulæ. There are instructive passages in the address recently delivered by Sir FRANCIS ACLAND as chairman of the Board at the opening of its nineteenth session. Summarising correspondence with registered dentists in Glasgow, he showed that the Board exercises an equitable jurisdiction and recognises that circumstances vary with the situation of the premises. The Board expects that a practitioner in a private residential street will be content to announce his place of practice with an ordinary professional plate. Elsewhere, amid shops and other professional premises, the dentist's name and description may be allowed in addition on not more than two windows. In busy commercial thoroughfares the Board has not objected to hanging or illuminated box signs of reasonable size, though it does not tolerate the use of "daylight signs" or intermittent or flickering lights of the kind familiar in the modern manifestations of commercial advertising.

No reasonable practitioner, we imagine, will think that the Dental Board has been unduly severe in imposing limitations. It is not desirable that the public should be encouraged to suppose, by analogy with the sphere of commercial propaganda, that the value of a dentist's skill is to be measured by the size, brilliance, or frequency of his notices. Some dentists in Glasgow and the West of Scotland, it appears, employ fascia boards with letters 12 inches high or more. The Dental Board is entitled to the support of the whole profession in endeavouring to put an end to such an abuse. It is gratifying to hear from Sir FRANCIS ACLAND that the Lanarkshire Dentists Society has notified its members that large letters or fascia or other notice boards are not permissible and has requested that all such announcements be removed. There is evidence that the more blatant forms of dental advertising are occasionally employed out of the desire to outbid a neighbour. Action by the local organisations which have the best possible knowledge of the circumstances is an appropriate remedy. Meanwhile the Dental Board is trying to raise the general standard progressively. As this is found possible, local diversities will diminish. There are, of course, some who would prefer that an absolute and uniform maximum of permissible display should be laid down irrespective of local circumstances. To this demand Sir FRANCIS ACLAND has made an effective reply. He points

out that in that event the Dental Board could never hope to win any case on appeal to the High Court. He pictures himself under cross-examination as an official witness on the appeal of a dentist whose name has been struck off the register for advertising his premises at a corner site on Piccadilly Circus with the locally familiar type of flashing or revolving coloured electric lights. He might have to admit in the witness-box that he regarded an illuminated box sign in Harley-street as even more flagrant and disgraceful in a professional sense; and yet such a box sign would, if the uniform standardisation were adopted which some now desire, be legitimate.

The Dental Board has achieved success in these matters by persuasion rather than by compulsion. But it must not be thought that there is no legal power to enforce the standard. As the chairman has lately explained, the judicial definition of infamous and disgraceful conduct in a professional respect will cover conduct by a practitioner in the pursuit of his profession "which will be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency." Those words, framed by Lord Justice LOPES and cited with approval by the Master of the Rolls in Allinson's case in 1894, are as applicable to the dental as to the medical practitioner.

ANNOTATIONS

THE COMMISSION ON NURSING.

Lord Crawford and Balcarres has consented to preside over THE LANCET Commission on the position of nursing. The terms of reference of the Commission are to inquire into the reasons for the shortage of candidates, trained and untrained, for nursing the sick in general and special hospitals throughout the country, and to offer suggestions for making the service more attractive to women suitable for this necessary work. The members of the Commission are:

The Earl of CRAWFORD and BALCARRES, P.C., K.T., F.R.S.
Prof. HENRY CLAY, M.A., D.Sc., late Professor of Social Economics in the University of Manchester.
Miss R. E. DARBYSHIRE, R.R.C., Matron, University College Hospital.
Miss L. CLARK, M.B.E., R.R.C., Matron, Whipps Cross Hospital.
Dr. ROBERT HUTCHISON, F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street.
Prof. F. R. FRASER, M.D., F.R.C.P., Professor of Medicine in the University of London, Physician to St. Bartholomew's Hospital.
Mr. A. LISTER HARRISON, J.P., Chairman, Committee of Management, Metropolitan Hospital.
Miss M. D. BROCK, D.Litt., Headmistress, the Mary Datchelor Girls' School.
Mrs. OLIVER STRACHEY, Chairman, Employments Committee, London Society for Women's Service.
Miss EDITH THOMPSON, C.B.E., Member of Council, Bedford College, University of London.
Sir SQUIRE SPRIGGE, M.D., F.R.C.P., the Editor of THE LANCET, with Dr. M. H. KETTLE, an assistant editor, as honorary secretary.

Any organisation or individual wishing to provide evidence for the Commission to consider, or to make proposals relating to the improvement of conditions of service of the nursing profession, is asked to communicate with the hon. secretary at THE LANCET Offices, 7, Adam-street, Adelphi, London, W.C.

THE EDUCATION OF THE DEAF.

A PRACTICAL step forward in the higher education of the deaf was taken at the recent meeting of the National Institute for the Deaf held at University College, London, and presided over by Lord Charnwood. There were present at the meeting representatives of educational authorities and special schools, and members of bodies such as welfare societies generally and the societies associated with the National Institute in different counties, while delegates from county councils also attended. Lord Charnwood laid before the meeting a scheme designed to fill an admitted gap in our system of national education, seeing that at the present moment the disability of deafness debars scholars leaving the primary schools from proceeding to institutions where they could receive a higher training; in this way valuable material is lost to the nation, while many persons quite capable of being not only self-supporting but useful citizens are driven into positions of helplessness. Lord Charnwood read to the meeting a letter from Sir Charles Trevelyan, President of the Board of Education, agreeing to the suggestion that there is a definite need of secondary schools for the deaf, which institutions had yielded good results already in the United States. Speaking to this authoritative text, Lord Charnwood placed before the meeting a scheme for promoting the higher education of the deaf by providing a school at which deaf children, after reaching the age of 16, would be assisted to study along particular lines especially fitted to meet their capabilities. The scheme was drawn up by a committee of the National Institute, and was placed before the meeting with a recommendation that an appeal should be made for £20,000, which would be required at the outset. Lord Charnwood allowed that more than double that sum would be required before the plans could be realised, but he could have left no doubt in the mind of the audience that the demand for public assistance was justified. Money we know is scarce, and forcible appeals reach daily those who are in a position to help good work; but alike from the public and the medical point of view a plan for the securing of the higher education of the deaf should be given every chance of early success. The careful training of the deaf would make self-supporting many who are now burdens on others, and would relieve the deadly isolation of the plight of the deaf. Further, among the deaf population, given a proper chance of self-expression, there would certainly be found, he reiterated, many whose work was valuable to society. This is a point which perpetually escapes the public attention, while it constitutes a most practical argument for public appeal.

CONSTITUTION IN GRAVES'S DISEASE.

MANY observers have pointed out that periodic variation of signs and symptoms is common in Graves's disease, and have reported difficulties in diagnosis to which exacerbations and remissions give rise. E. Moschcowitz [1] has carried these observations further by studying the temperamental peculiarities

[1] Arch. Internal Med., October, 1930, p. 610.

of patients for many years before they actually develop the disease. In his opinion these peculiarities are characteristic. Such people, he says, are always of a certain type—sensitive, restless, temperamental and emotionally unstable, with rapid pulse-rate and a tendency to tremor which increases at times of mental strain or emotional crisis. They are very sensitive to thyroid medication. The transition to true Graves's disease is often sudden, and the exciting cause is usually some form of psychic trauma, often fear. The signs and symptoms of hyperthyroidism are secondary phenomena, and the degree to which basal metabolism is increased is only an indication of the extent to which the thyroid is overactive, the value of the test being in some way equivalent to the value of the clinical thermometer reading in a febrile state. When as a result of operation or remission the basal metabolic rate becomes normal the constitutional factor remains unchanged. This is the true basis of the disease, and is often hereditary, but environment also plays a part in accentuating the tendency. Moschcowitz thinks the disease has a greater incidence in the female sex because women are more sensitive, while racially it is a product of the higher civilisations. Understanding of these constitutional factors shows at once that treatment directed to the thyroid alone is insufficient and likely to fail unless attempts are subsequently made to improve surroundings and mental outlook. Treatment, in fact, only begins after the operation has been performed, and in Moschcowitz's opinion complete cure is never possible.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE new school building, gift of the Rockefeller Foundation, has only been occupied since the recess of 1929, but in addressing the annual meeting of the Court on Nov. 28th, Prof. W. W. Jameson, the dean of the school, was able to speak of considerable development of work in the various divisions since that time. Sir Andrew Balfour, director of the school, was unfortunately prevented by illness from attending the meeting, and the dean presented the sixth annual report to the governors in his stead. During the past year the school has received delegates attending a conference organised by the Central Council for Health Education and, on a later occasion, members of the American Public Health Association. A study of the report of the board of management, presented by Sir Harry Goschen, shows the wide range of research now in progress in the various divisions; in bacteriology *B. aertrycke* and *B. abortus* are under investigation, as well as a Salmonella bacillus causing abortion in sheep; in biochemistry the metabolism of certain of the lower fungi are being studied, and in the division of chemistry applied to hygiene the blood changes in infection and the oxidation of domestic and trade effluents have been under consideration. In the department of entomology research has been chiefly concerned with the relation between insects and atmospheric conditions and with insect respiration; papers have been published by workers in the department of helminthology on ascariasis and on the fauna of sewage. A large number of protozoa have been studied, including the trypanosomidæ, certain coccidia, and the malarial parasite. Research on agricultural parasites is being carried out at St. Albans by the Institute of Agricultural Parasitology.

The public health division has been particularly concerned to provide courses of instruction for public health students, and this end has been forwarded by arranging for a series of lectures to be delivered by recognised experts. Coöperation on the part of various Government departments, local authorities and medical officers of health has made it possible for students to visit places of public health interest. A collection of plans and specifications is being collected with the aid of the public health service which will make it possible for the division to act, in time, as a clearing station for the public health data which accumulate from year to year. Already increasing numbers of persons are applying to the school for information and assistance, and many visitors are sent to the division by the League of Nations and the Rockefeller Foundation. Thanks to the Seamen's Hospital Society an adequate supply of clinical material has been available for teaching purposes at the Hospital for Tropical Diseases, and experiments are being made to prepare clinical cinematograph films, of which one on beri-beri has already been completed. The museum of the school is still incomplete but includes sections on water-supplies, sewage disposal, contagious diseases, milk production, and tropical medicine. The library is growing steadily, and the use of a medical library is demonstrated to the students at the beginning of every tropical course.

The financial position, though satisfactory at the moment, calls for the backing of a large endowment; but, as the annual report points out, anything in the nature of a hospital appeal would be unlikely to excite widespread sympathy. It is not generally appreciated that the familiar assertion that prevention is better than cure is a grotesque understatement. An increased income may ultimately be secured from the colonial Governments, and when Sir Andrew Balfour's health permits he will visit the colonies to make the necessary appeal on behalf of the school.

REACTION OF LIVING TISSUE TO IRRADIATION

A CRITICAL review of the harmful effects of irradiation by X rays and radium is contributed to the *Quarterly Journal of Medicine* for October by Sir Humphry Rolleston who gives references to no less than 288 original papers. The risks from the use of X rays were reported, he reminds us, within a short time of the application of these rays in medicine, and the succeeding years have shown that, while the effects of improper handling can be eliminated by the adoption of suitable precautions, the best means of avoiding damage to the tissues in the course of treatment have yet to be determined. Two sections of the review deal with matters which are warmly debated at the present time. The first of these is the possibility of stimulating normal tissues by such rays. Sir Humphry himself inclines to the view that any apparent stimulation of normal tissues is a temporary phase, followed invariably by more or less definite functional or organic deterioration. It is, we think, true to say that all the possible modes of stimulation have not yet been tried; if and when optimum conditions are found, it seems reasonable to suppose that the temporary phase of stimulation may be so lengthened as to rid the term of its usual rather restricted interpretation. The second crux is the question whether such rays can exert a stimulating action on malignant growths. From a consensus of the considerable number of papers on the subject Sir Humphry states that a stimulating action cannot be regarded as definitely established. But without regarding it as a certainty we must yet

reckon with the possibility of stimulated growth, although, if a malignant mass subsequently grows faster after irradiation than before, it is not safe to draw the conclusion that the growth has been stimulated. The inhibitory influence of the surrounding tissues of the body may have been impaired or the resistance diminished in other ways. Part of the divergence of opinion about stimulation may arise from too strict an interpretation of the term and too little attention to the processes involved. In the *British Journal of Radiology* for October, Dr. Takahashi describes a series of carefully planned experiments designed to show the effects of beta and gamma rays upon the processes of repair. Contrary to expectation he found that a region of normal tissue would sometimes react favourably to a strong dose of radiation when it did not to a weak dose. Further, he was able to show that the initial damage caused by the radiation had to be of a certain severity in order to provoke regeneration. In the interest of precision this term might be preferred to "stimulation" in describing the reactions to irradiation.

THE BOARD OF CONTROL.

UNDER the provisions of the Mental Treatment Act, 1930, the Board of Control will be reconstituted, as from Jan. 1st, 1931, to consist of the chairman and four other senior commissioners. Mr. Laurence George Brock, chairman of the present Board, will be chairman of the Board as reconstituted. The other members will be Mr. Simon John Fraser Macleod, K.C., on the recommendation of the Lord Chancellor, and Sir Charles Hubert Bond, F.R.C.P., Dr. Arthur Rotherham, and Mrs. Ellen Pinsent, on the recommendation of the Minister of Health.

INTEREST IN FOOD.

LAST Friday's discussion at the Royal Society of Medicine (reported on p. 1236) showed no waning of interest in the problems of national feeding, which were forced on Europe in 1914-18. Dr. Hamill himself brought out the point that in addition to negative factors there may be positive food factors which exert inimical effects on metabolism. We now that a substance occurs in cereals, especially in oatmeal, which reduces calcium retention and the calcification of bone, and which is neutralised by plenty of vitamin D, best obtained from milk and fat fish such as herring. This may be but the beginning of a new grouping of food factors. A correct plan of diet may imply a delicate and complicated balancing of such factors, far beyond our present knowledge. Although so many knowledgeable people took part in the discussion the question went unanswered whether the taking of vitamins in excess might not harm the elderly by enabling them to digest more easily and so be tempted to surfeit. Talking of individual adjustments, it was said that a man should reduce his diet when he gave up Rugby football, or, as the case might be, when he found himself out of work. The obvious improvement noted in the condition of the children in crowded areas during the last 20 years was ascribed largely to the greater availability of fresh fruit in these days. The disappearance of summer diarrhœa was credited to pasteurised milk, no mention being made of more efficient scavenging. It was stated that lionesses had more cubs when fed, not as has been usual on the muscles of old horses, but on good fresh meat with fat; that boys of Dr. Barnardo's schools have good teeth because they have to clean them twice daily and can only buy as a relish not sweets but fresh fruit. Mention was made of the importance of giving enough water to maintain the alkalinity of the blood alkali; an egg-farmer was quoted as having said that since giving the hens more water they came more quickly to laying and laid more eggs. This is enough to indicate that the discussion also was full of meat and deserved a full report.

TREATMENT OF PERNICIOUS ANÆMIA.

FURTHER work on the treatment of pernicious anæmia with desiccated defatted stomach is described by C. C. Sturgis and Raphael Isaacs in the *American Journal of Medical Sciences* for November. They employed hog stomach which was finely minced and dried at low temperature, after removal of the mesenteric and fatty layers. It was then defatted by repeated washing with light petroleum and yielded an almost tasteless product, which was given with tomato juice. A hundred grammes of fresh stomach gave 11–15 g. of dried material. Details are given of the successful treatment of 22 patients by this means, and it is stated that 7–10 g. of the dry material were found to be satisfactory as a maintenance dose. In the early stages 10 g. for each million deficit in the red cell count is recommended. An attempt was made to find out which part of the stomach supplied the active substance. Thus one patient, later reacting excellently to whole stomach, did not respond to treatment with the muscular layer, dried and defatted. On the other hand, five patients were treated with mucosa alone, also with practically negative results in four cases, while the fifth had a slight reticulocyte response but no complete remission until whole stomach was given. The authors explain these results by adopting W. B. Castle's hypothesis of an enzyme secreted by the mucosa and acting on muscle protein. In the present case this action is brought about during the preliminary mincing of the fresh stomach which allows the enzyme to make contact with the muscular layer. In the same number of the journal is an account, by J. E. Connery, of the treatment of pernicious anæmia patients with an aqueous extract of fish liver. In making the extract the oil was removed and fraction G, as described by Cohn, Minot, Alles, and Salter, was used. Six patients were successfully treated, details of each case being given. Mammalian meat, liver, and kidney were excluded from the diet. The livers of cod, haddock, and other fish were employed for the extract. Improvement followed comparable to that seen in treatment with mammalian liver.

THE STUDY OF CANCER IN ANIMALS.

THE forthcoming publication of the ninth scientific report to be issued by the Imperial Cancer Research Fund is announced in the annual report of the Fund for the year 1929–30, where Dr. J. A. Murray, F.R.S., the director, summarises the new work which will be included in the volume. The executive committee of the Fund take the opportunity of reminding the public that the Fund has from its inception deliberately devoted its energies principally to the experimental study of cancer in animals. While it is possible to approach certain of the problems of the origin of cancer by a study of the disease in man, the long duration of life in the human species limits the possibilities of successful attack. In every country in the world where cancer is studied systematically, organisations and institutes have been set up on the same

model as this Fund to acquire new knowledge by study on short-lived animals in order to economise time and money. Another reason for the restriction of the main endeavours of the Imperial Cancer Research Fund to the experimental study of cancer under laboratory conditions—and this restriction has not escaped criticism—is the fact that the whole group of tumours which can be transmitted specifically without the intervention of living cells can only be studied at present in the domestic fowl. A further use for experimental animals in cancer research is in trying out suggested lines of treatment. The executive committee regard the publication of new methods of treatment which have not fulfilled the expectations of their authors and of sufferers from the disease as one of the most discouraging features of the world-wide activity in cancer research during the last ten years. They believe that a more extended and critical utilisation of the methods and material made available by experimental cancer research, before advancing to the crucial, time-consuming experiments on man, would not only be the means of avoiding much unnecessary human suffering, but would accelerate progress. This suggestion should be followed up. The early work done under the auspices of this Fund proved conclusively that the new growths occurring spontaneously in animals correspond with those arising in human beings; and later work, in these laboratories and elsewhere, has left no doubt that cancer artificially produced progresses to a fatal issue if left untreated. It seems a plain duty, therefore, to study by preliminary trial on animals any new method of treatment before offering it for clinical application.

BACTERIOPHAGE IN CHOLERA.

ADDITIONAL information on the use of bacteriophage in the treatment of cholera has been sent us from India since the publication of our leading article on Sept. 20th. The work which Prof. d'Herelle began under the auspices of the Indian Research Fund Association has been carried on for a period of three years, now nearly expired, by his pupil and successor in this particular field, Dr. Igor Asheshov. In the period Jan. 1st to Sept. 1st, 1929, Asheshov addressed himself more especially to the laboratory side of this work, and his results [1] are of considerable interest, not only from their bearing upon the immediate practical problem, but from the light they throw upon certain aspects of bacteriophage behaviour. The main fact elucidated by Asheshov and his colleagues is that at least three strains of bacteriophage are necessary for effective and complete lysis of a culture of cholera vibrios. Three such types, named A, B, and C, will, as a rule, accomplish this end. The failure of permanent lysis is, as is well known, due to the emergence of "secondary" resistant cultures from a growth which is under the destructive influence of the bacteriophage. These mutant strains may, however, be susceptible to another strain of bacteriophage, and by the application of this principle Asheshov has selected his three types. These are complementary in their action, in that the secondary cultures resulting from the action of A are susceptible to B; but only partially so, since a second secondary culture will arise, which, in its turn, may be extinguished by C. This looks like selective action upon a heterogeneous population. The strains differ amongst themselves in other characters; thus, while A acts rapidly the duration of its effect is short and secondary cultures soon make their appearance. It is, moreover, somewhat liable to loss of virulence and only active against smooth vibrios, and it seems never to reach so high a concentration in media as do the other two strains. These are more polyvalent in action, lysing both rough and smooth strains and acquiring a high concentration in media. The C strain is less dramatically lytic than either the A or B. In the presence of all three types, Asheshov states that lysis is usually complete, unless the bacteriophages are of low virulence. As an outcome of these experiments it is to be noted that the preparation of a suitable bacteriophage is not as simple as has been widely represented, and that many of the important races are much less stable, and more delicate in cultivation, than was formerly appreciated. Efforts are accordingly, being directed to the establishment of a mixture of bacteriophages which would be at the same time polyvalent in action, rapid in producing lysis, and stable in solution.

In regard to treatment, Asheshov and his colleagues do not take up the position indicated in our leading article. They say: "we cannot do away with saline and alkaline infusions. . . . We continue our experiments in the treatment because we strongly believe that with the modification of our bacteriophage cultures the results will be improved. However we think that the main rôle of the bacteriophage will be not in the treatment of cholera, but in its prevention." This is a weighty pronouncement in the face of d'Herelle's statement that "the administration per os of cultures of bacteriophages possessing a high virulence for the cholera vibrio constitute the specific treatment of Asiatic cholera." [2] Further the belief that this agent should be exclusively administered by the mouth has evidently been abandoned, since Asheshov states that he is experimenting with intravenous injections with encouraging results.

The work of Asheshov bears the stamp of care and caution. If he finally succeeds in establishing the position of the bacteriophage in reference to cholera—which with different reports has varied from that of an almost unfailing specific to that of an inert substance—he will have rendered India no small service.

A MEMORIAL TO GEORGE VIVIAN POORE.

THE National Homecroft Association is proposing to erect a memorial to Dr. George Vivian Poore whom they regard as an advocate of homecrofting although he did not use that name for it. Poore certainly deserves to be remembered, for in many ways he was a remarkable man, whether considered as a physician, clinical teacher, author, or sanitarian. At his best there was something compelling about his light-hearted brilliance. Of slight build and delicate physique he possessed a voice with which he filled the largest room with ease, and his after-dinner speeches and other public utterances were long remembered by those who heard them. He was a clear and learned exponent of the principles of forensic medicine, lecturing on the subject at Charing Cross and later being professor of medical jurisprudence at University College. At both the medical school to which he was attached he was a pioneer in the study of medical electricity, but it was by his work as a practical sanitarian that he was best known. His contributions on matters like the hygiene of the street

[2] Indian Med. Res. Memoirs, 1930, No. 14.

the water-supply of country districts, the curious ignorance of sanitary affairs, appeared in our own columns; his clear and incisive style was displayed to great advantage in his book entitled "London, Ancient and Modern, from the Sanitary and Medical Point of View." In his dislike of the water-carriage system of sewage disposal Poore stood almost alone, and as far as town life is concerned he was fighting a losing battle. Pull the chain and let the sanitary authority do the rest has won the day. But in the garden of his house at Andover he raised luxuriant crops of fruit and vegetables by manuring with a mixture of fresh fæces and earth, at the same time proving that the subsoil water remained perfectly wholesome and capable of use as a domestic supply; and he may well have been right in believing that in the country such simple and conservative methods are both feasible and fruitful. He held, as Dr. F. G. Crookshank puts it, a steady and unwavering belief in the national importance of a domestic agricultural economy, or polity, that would render possible, profitable, and attractive a life on the land. Agriculture, Poore declared, is the corner-stone of preventive medicine. His ideals have found a sponsor in the Homecroft Association, which has been trying to put them into practice on their estate near Cheltenham. The memorial, for which they hope to raise sufficient funds from among Poore's old students and friends, is to be a special croft with a building about twice the size of the others, to serve partly as a dwelling and partly as a school. The proposals were outlined by Prof. J. W. Scott at a meeting recently held at Church House, Westminster. Some £250 has already been subscribed and a further sum of £200 promised. All who are interested are invited to communicate with Prof. Scott, at University College, Cardiff.

"STATUS THYMO-LYMPHATICUS."

In 1927 Prof. Major Greenwood and Miss Hilda Woods published a study of status lymphaticus,[1] in which they maintained, first, that to base a diagnosis on the weight of the thymus alone was unreasonable, a conclusion also reached by J. A. Hammar; secondly, that sudden death was no more the fate of people with heavy thymi than of others; and thirdly, that the concept of a status or diathesis explained by a thymic abnormality was "a mere farrago of random assertion and debased tradition." Since then Hammar has published a second volume[2] in which a special chapter is devoted to 44 cases of alleged status lymphaticus. He declares that in these cases the thymus is not only not enlarged, but also fails to show any hyperplasia of the medulla, any accidental involution, or any new formation of Hassall corpuscles. He concludes that cases of "inexplicable" death may be the expression of some physiological abnormality of the endocrine system and that stigmata—a reduction or cessation of new formation in the Hassall corpuscles—may be found in the thymus. These stigmata, however, have only a statistical significance and cannot be applied as criteria in clinical or medico-legal practice. Prof. Greenwood, discussing these findings,[3] examines Hammar's data arithmetically. He forms a table of all the children who died suddenly with negative or trivial post-mortem indications, showing the conditions in the thymus, and a similar table of normal children. These tables show that Hammar's conclusions are amply supported by figures. There is no appreciable difference between the thymus of normals and that of "sudden death" cases, but a count of the Hassall bodies might possibly be of some value for group differentiation, if made with care and accuracy. The variability of this measure is, however, nearly 50 per cent. in a normal series, so that it is obviously useless as an individual criterion. Prof. Greenwood suggests that, now that the thymic theory is exploded, the time has come for some careful work on other organs and functions, in an attempt to elucidate the mysterious condition improperly known as status thymo-lymphaticus.

FOUNDATION DAY AT THE UNIVERSITY OF LONDON.

The first official celebration of Foundation Day of the University of London took place on Nov. 28th. The ceremony took the form of a procession in full academic dress through the Great Hall of the University, an impressive charge from the Vice-Chancellor, and the investment of the successful candidates for higher degrees. The company reflected well the prestige of this comparatively young university, which is already great in achievement. Diplomats, statesmen, masters of city companies, and mayors of the boroughs which make up the county of London, as well as those more directly concerned with education or with the arts and sciences, assembled to do honour to the University, and remained to enjoy the pleasant party which followed the more formal proceedings. The guests, who included friends of the new masters of surgery and doctors of science, medicine, laws, and literature, who were presented for degrees, were received, in the unavoidable absence of the Chancellor, Lord Beauchamp, by the Vice-Chancellor, Rev. John Scott Lidgett, the Chairman of Convocation, Mr. S. L. Loney, the Chairman of the Court, Lord Macmillan, and the Principal, Mr. Edwin Deller, LL.D. The Vice-Chancellor in his charge recalled the fact that the centenary of the foundation of the University was approaching, and that it was hoped to celebrate it fittingly in the new buildings at Bloomsbury. Among the doctors of medicine on whom degrees were conferred were Dr. T. Anwyl Davies, who was awarded the university medal in medicine, and Dr. Dorothy S. Russell, who was awarded the university medal in pathology. During the evening the band of the Scots Guards played a programme of music, and in the library reading room a small exhibition of rare and interesting books, including the Prince of Wales' MSS., "Life of the Black Prince" (circa 1385) was on view.

COMPARATIVE PATHOLOGY OF TUBERCLE.

In a monograph published this week by the Medical Research Council,[1] Dr. H. H. Scott sets out the material drawn from post-mortem examinations made by him on 300 fatal cases of tuberculosis occurring amongst Chinese of the labouring class in Hong-Kong and also on a series of wild animals dying of tuberculosis whilst in captivity at the London Zoo. The writer has availed himself of a unique opportunity to make a comparative study of the morbid anatomy of tuberculosis in two groups not hitherto submitted to careful examination. That there is a close analogy between tuberculosis in wild animals living in captivity

[1] Tuberculosis in Man and Lower Animals. Special Report Series No. 149. H.M. Stationery Office. Pp. 270. 4s.

and tuberculosis in human races that have only recently come into contact with civilisation is now well recognised. They are both examples of tuberculosis in virgin soil. Dr. Scott's monograph, therefore, helps to fill a gap, so that we now have a more or less continuous record of the study of tuberculosis from the florid disease as it affects captive wild animals, and the so-called unsalted races at the one end of the scale to the modified disease as it is seen in domesticated animals and the adults of immunised races at the other end. Between these two extremes is the tuberculosis of the unprotected infant both in immunised and non-immunised races. In addition to the valuable post-mortem records of the Hong-Kong infants, an unprotected collection of cases, the monograph is a mine of information for the study of the natural history of the disease, containing as it does a record of many autopsies made by the author, when pathologist to the Zoological Society of London, on ungulates, carnivores, monkeys, birds, and reptiles. There are also two concluding sections dealing with the comparative pathology of tuberculosis and mycosis in birds and in mammals. Dr. Scott finds these two diseases occurring together not as a mycotic implantation on old phthisical cavities but as two separate infections developing side by side in the wild animal, an example of symbiosis which we do not recollect having been dealt with at any length previous to Dr. Scott's monograph.

A COMMITTEE ON MENTAL DEFICIENCY.

THE British Medical Association has decided to appoint a committee to report on the various medical problems presented by mental deficiency, more especially with regard to methods which have been suggested to reduce its incidence and to the facilities for medical education in this subject. The Council of the Association was led to take this step at its last meeting by the receipt of a communication from the National Council of Women in Great Britain, urging that definite practical means should be taken to prevent the propagation of the mentally defective, the idea being the appointment of a Royal Commission of Inquiry. Dr. R. G. Gordon, who moved the appointment of a B.M.A. committee, maintained that mental deficiency was a medical matter, and deprecated the tendency in this country for its discussion to get into the hands of lay bodies, whether educational or social. The problem should, he thought, become the responsibility of the whole medical profession, and he regretted the limited opportunities for education on this subject afforded by the medical schools. Dr. Brackenbury felt that medicine was chiefly concerned with the origin and propagation of mental deficiency; its treatment was not wholly a medical question. There is welcome evidence in various directions of awakening interest in the problem as a whole. In our review columns this week will be seen a notice of a book in which Dr. Henry Herd endeavours to give a general working basis of psychological principles for the student of mental defect. His object has been to provide a book, midway between the medical and psychological, containing sufficient material from both aspects for the medical officer when called upon to examine children whose mentality is below the average. Another review illustrates the extent to which we are indebted to those outside medicine for the stimulus to such study. The late Miss Margaret Macdowall's account of her own experience in the training of mentally defective children has been reissued as a memorial volume. She spent her life in personal study of the special characteristics of mentally defective children, and much of her teaching has now become accepted tradition. The committee of the B.M.A., it may be added, consists of its officers ex officio and the following members: Prof. R. J. A. Berry, Dr. R. Langdon-Down, Sir Ewen Maclean, Dr. R. G. Gordon, Dr. A. F. Tredgold, Dr. W. Langdon Brown, Dr. R. M. Stewart, Dr. E. O. Lewis (Board of Control), Dr. Letitia Fairfield, Dr. H. P. T. Young (H.M. Prison, Wormwood Scrubs), Dr. J. S. Manson, Prof. F. A. E. Crew, Dr. H. C. Bristowe, and Dr. L. A. Parry. In addition a representative is to be appointed by the Society of Medical Officers of Health, and another by the Royal Medico-Psychological Association.

MORTALITY FROM APPENDICITIS.

IN a leading article in our issue of Nov. 22nd we called attention to the high mortality from acute appendicitis and quoted certain figures in illustration. These figures were ill chosen for their purpose, since they are not in fact comparable. Prof. Grey Turner's death-rate of 3·5 per cent. in 2252 cases of his own includes "interval" operations, as is clearly shown in his original letter in THE LANCET.[1] If such operations are excluded we are left with 1339 cases of truly acute appendicitis, with a mortality of 5·7 per cent. The figure given for two London teaching hospitals (6·2 per cent.) also requires revision, for reference to Mr. Love's Hunterian lecture[2] shows that he has deliberately excluded "early cases in which the infection is still limited to the appendix and which are universally treated as a surgical emergency." His object in so doing was to demonstrate that the later cases, if treated with "discrimination and not according to rule of thumb," have a lower immediate mortality and fewer complications or sequelæ than those operated upon as soon as seen.

THE PRESIDENT OF THE ROYAL SOCIETY.

ON Dec. 1st, at the 268th anniversary of the Royal Society's foundation, Sir Frederick Gowland Hopkins, M.D., was elected to the presidency in succession to Sir Ernest Rutherford, O.M. Since 1914 he has occupied the important chair of biochemistry at Cambridge University, and last year his outstanding contributions to the study of accessory food factors won him the Nobel Prize for Medicine in conjunction with the late Prof. Christiaan Eijkman. Sir Frederick Gowland Hopkins became a Fellow of the Royal Society in 1905, and received the Royal and Copley Medals in 1918 and 1926. His latest honour is a further source of pleasure to the medical profession and especially to those who have been in any way associated with him.

THE scientific committees of the British Empire Cancer Campaign have produced a short authoritative work entitled The Truth About Cancer. At the annual general meeting of the body, held at the House of Lords last July, H.R.H. the Duke of York, the President, strongly approved of the intention to issue such a book, which aims at placing before the public a true picture of what relief may be reasonably expected when advantage is taken of the benefits of modern treatment. The work appears as we go to press.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCXIV.

AFTER-TREATMENT OF SOME COMMON OPERATIONS.

PART III.*

SPECIAL OPERATIONS: GASTRO-JEJUNOSTOMY.

WHEN gastro-jejunostomy is performed for severe pyloric or duodenal obstruction, a common complication is *acute dilatation of the stomach*. To anticipate this and avoid its danger I complete the operation of gastro-jejunostomy, when the stomach is large and atonic, by performing also a temporary jejunostomy, through which the patient may be fed. Acute dilatation in which distension is a prominent symptom may be distinguished from intestinal paralysis by the nature of the vomiting with its repeated regurgitation of foul fluid gastric contents. There should be no delay in passing a stomach-tube and evacuating the large amount of fluid that collects in the stomach, and this should be repeated every few hours.

Diet.—In a straightforward case a patient after gastro-jejunostomy may be fed according to the following scheme.

While he is recovering from the anæsthetic for the first 2 hours ½ oz. of water is given frequently.

Second 12 hours: 1 oz. of such clear fluids as albumin water, panopeptone, glucose and water, and raisin tea is given hourly.

Third and fourth 12-hour periods: 1 oz. of clear fluid and 1 oz. of peptonised milk are taken alternately every hour, if awake.

Fifth 12-hour period: 2 oz. of peptonised milk hourly.

Sixth 12-hour period: alternate feeds of 3 oz. of peptonised milk and 3 oz. of citrated milk every two hours.

Seventh 12-hour period: 3 oz. of citrated milk every two hours.

On the fourth day thin bread and butter, chicken cream, and pounded fish are allowed, in addition to milk, which is citrated until the end of the first fortnight.

On the fifth day cold fresh ham and tongue are added to the diet.

From the fourth day onwards, three times a day and the last thing at night, a teaspoonful of the alkaline powder recommended by H. MacLean is given—i.e., sod. bicarb. one part, mag. carb. (powd.) two parts, bism. oxycarb. two parts.

Cases of perforated duodenal and gastric ulcer are usually suffering from starvation and are fed, after operation, in a similar way.

Hæmorrhage.—A serious occasional complication of gastro-jejunostomy is hæmorrhage. It is, perhaps, not sufficiently known that the most powerful remedy to stop the bleeding is blood transfusion; while preparation is being made for this, hæmoplastic serum should be given subcutaneously. Milk should not be long withheld after such a hæmorrhage, for regular small feeds counteract hyperacidity.

Cholecystectomy.

Operating through a right paramedian incision, I always take the precaution of inserting a small tube near the common bile-duct and bringing it out through a small incision at the outer border of the rectus muscle; this tube is turned daily and there is usually some escape of old blood about the sixth day. If no bile appears the tube is removed at the end of a week, but if leakage of bile occurs the tube should be kept in place for a week after bile ceases to appear. Unless this is done there is the danger of extravasation of bile into the peritoneum in a situation where it is difficult to detect, either the right posterior subphrenic space or the lesser sac of peritoneum; such extravasation occurs insidiously and causes obstruction of the colon and the duodenum, and in a fat patient may be very difficult to get at and drain, owing to dense omental adhesion. After gall-bladder operations especially it is most important that the daily intake of fluids be very large.

Suprapubic Prostatectomy.

An open operation is performed in the advanced Trendelenburg position; this minimises hæmorrhage during the enucleation of the prostate. A large tube is sewn into the bladder and attached also to the skin; collapsible tubing (Paul's) carries off the urine, and can be detached daily for irrigation of the bladder with glyco-thymolin (one drachm to the pint); for this purpose a rubber catheter is passed within the large drainage-tube down to the prostatic bed. The wound remains watertight until the eighth day, when the large tube is removed and a smaller one inserted in its place, a Hamilton Irving box being applied; within the box a gauze bag containing boric crystals should be placed, resting on the skin. From the eighth day onwards, until the wound is too small to admit a catheter, the bladder is irrigated twice daily with concentrated boric solution. On the tenth day a full-sized silver bougie is passed along the urethra into the bladder. Before and after operation, one-grain methylene-blue pills or pyridium gr. ¼ are administered three times a day. When the patient for the first time passes a considerable quantity of urine naturally, it is not unusual for him to have a rigor, and it is wise to warn him of this beforehand.

Primary hæmorrhage from prostatectomy is guarded against by carefully ligaturing or under-running all bleeding-points before suturing the bladder wall, and by keeping up the Trendelenburg position after the patient is put back to bed, and during his transfer from the theatre; packing of the prostatic bed is to be avoided because it encourages sepsis and sloughing. In reactionary hæmorrhage the bladder may fill with clot, so that the mouths of bleeding veins are kept open; in such cases it is sometimes sufficient to empty the bladder of blood and irrigate the prostate bed with boric lotion; if, however, the hæmorrhage is persistent, it is less dangerous to give an anæsthetic and suture the bleeding-points than to allow the patient to lose much blood. Secondary hæmorrhage occurs after the first week and can be prevented in most cases by leaving no remnants of prostate or tags of mucous membrane at the time of operation, and by irrigating the bed of the prostate every 12 hours during the second week. Severe secondary hæmorrhage calls for exposure and suturing of the bleeding vessel.

Epididymitis, even going on to suppuration, used to be a not uncommon complication of prostatectomy about the third week. It is prevented by ligaturing and dividing each vas deferens at the upper part of the scrotum, either at the time of the operation of prostatectomy or of a preliminary suprapubic drainage.

Though the patient is passing water freely by the urethra, there is often some delay in the final closure of the suprapubic urinary fistula. In such a case a soft catheter is tied in the urethra and kept in position for 48 hours, during which time the fistula will usually close. The catheter must not be kept in position

* Parts I. and II. appeared in our issues of Nov. 22nd and 29th respectively.

unchanged for more than two days or it will cause urethritis and infection of the prostate bed. This manœuvre often needs repeating before final success attends it. More persistent fistulæ may be due to infection, to obstruction of the internal meatus by scar tissue, prostatic remnants or a flap of mucous membrane, or to the formation of a phosphatic calculus. Such complications may be prevented by a thorough open operation, but if they occur they must be dealt with by reopening the bladder and dealing with the trouble from above.

For threatening or established *anuria* following prostatectomy, theocin sodium acetate is given in gr. 10 doses every four hours by mouth and 5 per cent. glucose solution intravenously. Rectal therapy and enemata should only be used with great caution after this operation, for there may be enough bruising and œdema of the mucous membrane to make its perforation by a rectal tube or catheter very easy.

After every operation for prostatectomy the patient should drink 100 ounces of bland fluids every day for several weeks.

Operations for Hæmorrhoids.

For hæmorrhoids it seems that the dissection and ligature operation is still the surest means of obtaining a permanent cure, valuable as is the injection treatment in suitable cases. Every tiniest bleeding-point is carefully ligatured and all ligatures are left long, so that at the end of the operation there may be fifty or more ends of catgut protruding from the anus. I therefore never employ the so-called "tell-tale" tube; it causes pain and spasm and in my view increases the risk of hæmorrhage; nor will it certainly reveal bleeding, for it may be blocked by clot, and the only reliable signs of hæmorrhage are the pulse and general condition. Morphia is given hypodermically if the patient has pain, but this is often unnecessary in the absence of a tube; there is no advantage in using morphia in the form of a suppository.

On the fourth day the bowels are opened with castor oil, and before they act olive oil is injected into the rectum. On the fifth, seventh, and ninth days the finger must be inserted up to its base through the anal canal; this prevents adhesions and the stricture that is one of the common complications of an uncared for hæmorrhoid operation. When the last ligature comes away, about the tenth day, healing may be considered to have taken place and the patient may leave his bed.

Amputation of the Breast.

After radical amputation of the breast there are three important points in treatment. It is usual to insert deep mattress sutures of the skin so as to evert the edges of the wound; these should be retained for at least a fortnight, otherwise the flaps will pull apart and separate, or at least stretch the scar. The dead space is drained by a long tube reaching to just below the clavicle and curving round the back of the axilla to its exit through a puncture wound below; it must be borne in mind that considerable muscle exudation goes on for a week or more, and premature removal of the tube allows a collection of fluid to form, especially just below the clavicle. In dressing the case at the end of the operation the arm should be kept from the side by padding at an angle of about 40 degrees; on the second day the arm is set free and the patient is persuaded to place her hand behind her neck and to persevere until she can touch the opposite ear. She can practically always do this, though it seems to her at first to be impossible, and if she carries out this exercise daily she will escape the painful and disabling loss of abduction that used t follow such operations frequently.

Operations on the Lower Limb.

Let us now take, as an illustration of operations o the lower limb, the removal of a semilunar cartilage This operation is performed with a tourniquet, s as to avoid the entrance of blood into the joint an obviate the use of swabbing. Before the tourniquet is removed the dressing is applied, with an even laye of wool all round the limb extending well above an below the joint and bandaged in position wit moderately firm pressure; over this another laye of wool is bandaged with rather firmer pressure The limb is then held almost vertical and th tourniquet removed. The limb is kept as high a possible, with the hip flexed to about 70 degrees whil the patient is returned to bed, and this position i maintained continuously for 10 days, by placin a chair upside down on the bed and covering it wit pillows to provide a firm and comfortable slopin surface. The bulky wool dressing provides sufficien splinting. At the end of 10 days the dressing i removed, the stitches are taken out, and the patien lying on his side, actively flexes his knee beyond right angle. It is almost dramatic to see how easil he does this, as a result of keeping the joint free fro blood and œdema during and after the operatio I allow the patient to walk on the twelfth day an find that recovery of the thigh muscles is most rapi if the limb is used naturally and massage is no employed. A patient of mine played tennis quit happily within three weeks of this operation. Th same principles apply to more serious operations o the lower limb, such as bone grafts, and traumati œdema is so certainly prevented by the exaggerate elevation that I do not hesitate to apply plaster-o Paris over the dressing at the end of the operatio and leave the limb untouched for as much as a mont before even removing the sutures.

INDIAN MEDICAL SERVICE.

R. M. L. Still to be Capt. (on prob.).

EXTENSION OF SHEFFIELD ROYAL INFIRMARY.—Prince George recently opened extensions of this hospita which have cost £24,000. The new building, which is o concrete, comprises a casualty department, a theatre massage and dermatological departments, and a self-containe X ray department, with pathological, physiological, an biochemical laboratories.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL.

(*Continued from p. 1199.*)

THE Council turned to the consideration of

Penal Cases,

receiving first the report of the Dental Board. According to custom, the Council heard the cases in public and deliberated on them in camera, after which the President announced their finding.

CASES REPORTED BY THE DENTAL BOARD.

The Case of Francis Leonard Harrison, registered as of 13, Bute-street, Treherbert, Glam., "Dentist 1921."

The Dental Board, having considered the conviction of Francis Leonard Harrison, reported as follows: Francis Leonard Harrison had attended on May 14th, 1930, and applied for the adjournment of the consideration of his case until the November Session, in order that he might have a better opportunity of providing himself with legal assistance. His application had been acceded to. Mr. Harrison had not attended the inquiry on Nov. 12th, 1930, nor had he been represented. The following facts had been established by the evidence: Francis Leonard Harrison had, at the York Assizes, commencing on Nov. 19th, 1929, been convicted of the following felony—namely, of embezzling the sum of three pounds, the moneys of Norman Tetlow Williamson, and other sums, and of fraudulently converting the said sums to his own use and benefit, contrary to Sections 17 and 20 of the Larceny Act, 1916, and of the following misdemeanour—namely, of falsifying accounts contrary to Section 1 of the Falsification of Accounts Act, 1875, and had been sentenced to 12 months' imprisonment in the Second Division.

Mr. Harrison had written to the Board craving their indulgence in his absence. He had stated that his case was as follows: (1) His offence was in no way connected with his profession, and was simply a matter of account between employer and employee, and in no way had he abused his professional duties. (2) His employer had done exactly the same thing with his immediate predecessor, that is, engaged him on salary and commission, and then, on his leaving, withheld the money owing for commission. (3) He was 46 years of age, and had spent the whole of his adult life in the practice of dentistry, over 26 years, without a fault of any kind against his professional character. (4) He was incapable of earning a living in any other profession or industry. Mr. Harrison also stated that his children, a boy and a girl, had by their application and industry obtained scholarships to universities, and if he was not allowed to practise they would be unable to continue. It was proved at the trial that the approximate amount of money missing was altogether between £100 and £150. Harrison's commission would amount to about £25.

The Board recommended that the name of Mr. Harrison be erased from the Register. Their solicitor, Mr. Harper, laid the facts before the Council. Mr. Harrison was not present, nor was he represented. The Council decided to direct the Registrar to erase his name.

The Case of John Patrick McLaren, registered as of 10, Wood-street, Doncaster, "Dentist 1921."

The Dental Board, having considered the complaint against John Patrick McLaren, reported as follows:

On Nov. 13th, 1930, the inquiry was held, when John Patrick McLaren attended in person. The following facts were established by the evidence:—

That in or about the month of June, 1928, John Patrick McLaren gave to the Independent Order of Oddfellows (Manchester Unity) Friendly Society (Approved Society No. 123) a fraudulent estimate of dental work to be done for one Thomas Henry Singleton, a member of the said Order, and subsequently certified the completion of work, although not done, and fraudulently obtained payment in respect thereof.

Mr. McLaren admitted to the Board that he had had the money, and expressed his regret. He said that he required it to pay his retention fee to the Board.

The Board considered that the name of Mr. McLaren ought to be erased from the Register. Mr. Harper addressed the Council. Mr. McLaren was not present, and was not represented. The Council directed the Registrar to erase his name.

MEDICAL CASES ADJOURNED FROM PREVIOUS SESSIONS.

The Case of Donald McGregor Stewart, registered as of 5, Waunwen, Nantymoel, Glam., L.R.C.P. & S. Edin. 1917, L.R.F.P.S. Glasg. 1917, who had been summoned to appear before the Council in November, 1929, on the following charge:—

That you were convicted of the following misdemeanours, viz.: (*a*) At the Bridgend Petty Sessions: (1) On Oct. 16th, 1926, of being drunk whilst in charge of a motor-car, and were fined £3 and your driving licence suspended for 12 months; also of driving a motor-car to the danger of the public, and were fined £1; (2) on Oct. 8th, 1927, of being drunk, and were fined 10*s.*; also of using indecent language, and were fined 30*s.*; (3) on Nov. 26th, 1927, of using indecent language, and were fined £3 or 14 days; (4) on June 16th, 1928, of using indecent language, and were fined £2 or 14 days' hard labour; (5) on August 18th, 1928, of being drunk and disorderly, and were fined £1; (6) on May 11th, 1929, of using indecent language, and were fined £3 or 14 days' hard labour; and (*b*) at the Ystrad Police-court; (7) on June 25th, 1928, of using indecent language, and were fined £3.

There had been no complainant in this case.[1] Mr. Stewart had given assurances of future sobriety at the original hearing in November last, and the Council had suspended judgment for 12 months.

Mr. Stewart appeared and confirmed his assurances. The Council decided that his name should remain on the Register.

The Case of Ratilal Shivlal Shah, registered (Colonial List) as c/o Ujamshi S. Shah, High Court Pleader, Rajkot, India, M.B., B.S. 1922, U. Bombay, who had been summoned to appear before the Council on the following charge:—

That, being a registered medical practitioner, you have advertised for the purpose of obtaining patients or promoting your own professionalad vantage, viz.: (1) By the issue of two leaflets in respect of two medicines concocted by you, to wit "Shwetanjan" and "Muktanjan." (2) By calling your private home or dispensary "Dr. Shah's Eye Hospital" or "Dr. Shah's Ophthalmic Hospital." (3) By inserting, or sanctioning the insertion, or acquiescing in the insertion, in the March, 1928, number of a Gujarati paper called *Sharda* of an advertisement of the above-mentioned remedies. (4) By inserting, or sanctioning the insertion, or acquiescing in the insertion, on another page of the issue of the said paper *Sharda*, a portrait of yourself with a laudatory notice below such portrait. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The Council's attention had been drawn to this case by the Bombay Medical Council. At the former hearing the Council had found the evidence insufficient for a decision.[2]

Dr. Shah was not present but was represented by Mr. H. F. Parfitt, of Messrs. Minett, May and Co., solicitors. Mr. Harper addressed the Council and said that an application by Dr. Shah for restoration had been refused by the Bombay Medical Council, "at present." There were no new facts to lay before the Council, but it had never been clear how these advertisements came to be printed; it did not seem likely that the editor or any layman had made them up.

Mr. Parfitt addressed the Council and summarised a new declaration from Dr. Shah, stating that he had withdrawn the wrappers as soon as the Bombay Medical Council had objected to them. He pleaded an unwitting infringement of the Rule. The editor of *Sharda* had denied on oath that Dr. Shah had had anything to do with the advertisement.

After deliberation the President announced that the Council had found charges 1 and 2 proved to

[1] THE LANCET, 1929, ii., 1254.
[2] THE LANCET, 1929, ii., 1194.

their satisfaction and had decided that these constituted infamous conduct. They had directed the Registrar to erase Dr. Shah's name from the Register.

The Case of Frederic William Barton, registered as of 56, Erith-road, Bexley Heath, Kent, M.R.C.S. Eng. 1889, L.R.C.P. Lond. 1889, L.S.A. Lond. 1889, who had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you abused your position by committing adultery with Mrs. Lizzie Catherine Thomas, a widow, with whom you stood and with whose deceased husband you had stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated Jan. 16th, 1930, in the case of Barton *v.* Barton, in which you were the respondent; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

There had been no complainant in this case.[3] At the conclusion of the hearing the President had announced the Council's decision as follows: The Council are not satisfied with the evidence which has been adduced, and have adjourned this case for six months. The parties will be directed to appear again, bringing further evidence, so that we may come to a decision as to whether the inquiry is sufficient or not. Notification will be sent to the accused practitioner that he should appear in six months, and tender evidence in support of his side of the case.

The Council's solicitor said that Dr. Barton had married Mrs. Thomas and that Mrs. Barton was unwilling to give evidence. There were, therefore, no further facts to be laid before the Council, and the case was dismissed.

TWO CASES OF IMPROPER CERTIFICATION.

The Case of Simeon Moses Cohen, registered as of 1, Ynyswen-road, Treorchy, Glam., M.R.C.S. Eng. 1919, L.R.C.P. Lond. 1919, who had been summoned to appear before the Council on the following charge :—

That, being a registered medical practitioner, you on March 15th, 1930, issued the following certificate, viz :—

The Surgery, Treorchy, 15/3/1930.

I certify that W. King is unable to follow his employment since 15/3/30 owing to illness.

S. M. Cohen,
Surgeon.

Whereas you had not seen or examined the said W. King on March 15th, 1930, which certificate was misleading and improper; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainants, the Great Western Railway Company, were represented by Mr. Geoffrey Smallwood, counsel, instructed by the company's solicitor. Members of the Medical Defence Union withdrew. Dr. Cohen attended in answer to his notice and was represented by Mr. O. Hempson, solicitor to the Medical Defence Union.

Mr. Smallwood said that the company did not desire to press the case against the respondent, but merely to lay the facts before the Council for their adjudication. Dr. Cohen had a branch surgery at Treherbert. On March 14th a goods guard named William King had sent word that he was ill and could not attend for duty. Later in the day William Venn, the stationmaster, had seen him at the adjacent hotel, obviously in a state of intoxication. He had, therefore, sent a message to King's home that King must produce a medical certificate if he desired to be excused his period of duty, which began at 6 P.M. The next evening Venn had received the certificate which was the subject of the case. He had not been satisfied, and had gone to Dr. Cohen, accompanied by George Harris, traffic clerk of the station. Dr. Cohen had admitted quite frankly that he had not seen King at the time he had sent the certificate. Later on he had sent a letter to the railway company saying that he had been very busy at the time; that he had known King and his wife very well, and believed them to be honest, and that he had refused to sign the other certificates for which he had been asked. Counsel submitted that the certificate was obviously misleading, and was, on the face of it, unsatisfactory because the illness was not specified. The company employed a large number of men and were bound to rely on the certificates of doctors. If they could not much loss of time would be caused, and the discipline of the men would be undermined if they could obtain certificates as this one had been obtained.

Mr. William Venn confirmed the facts stated by counsel and said that Dr. Cohen had remarked that doctors usually endorsed certificates if they were unable to see the patient at the time. In answer to the Legal Assessor, he said that, as King did not belong to the company's provident society, the certificate was of no use to support an application for sick pay.

George Harris, traffic clerk, testified that he had accompanied Venn to see Dr. Cohen. The next day respondent's partner had informed him over the telephone that King was suffering from influenza and heart trouble.

Mr. Charles Simkins, general assistant to the superintendent of the line, said that great reliance and respect were accorded to medical certificates and that if they were improperly given it would interfere greatly with the conduct of disciplinary cases. In answer to the Legal Assessor, he said that he did not think that the provident fund would accept the certificate in question, as the illness was not specified. It might be accepted to excuse a man from duty.

In answer to the President, witness said that the stationmaster would not have been entitled to accept the certificate in question.

Mr. Hempson then called Dr. Cohen, who said that a relative of King's had come to ask him to visit King next morning. The visitor had asked for National Health Insurance and club certificates, and witness had declined to give them. He had then asked for a certificate to release King from work; witness had replied that it was impossible to give a certificate releasing from work unless he had seen the man. He had, he thought, offered to go and see King that night and take the certificate with him, but the messenger had said that King had to report for duty or send up a medical certificate, and that a substitute had to be found before 6 o'clock. There would, therefore, have been no time to see him before the certificate was wanted. The messenger had assured him that King was in bed and ill. Witness had thought the matter over; King had been known to him for years, and he would be seeing him the following morning and no monetary question was involved. The question he had unfortunately put to himself was: did he think the man was genuinely ill? He had neither asked nor received any payment for the certificate. King had been found next morning to be genuinely ill.

In answer to a member of the Council, witness denied having used the word "endorsed." It was not his habit to use the word "illness" when he had not seen the patient, as had been suggested. He regretted extremely that this certificate was laxly worded and agreed with what counsel for the railway company had said concerning the reliance placed by the Company on medical certificates.

The President asked the witness what he meant by the words "I certify," and witness admitted in answer that the words meant that he declared from his certain knowledge that the facts were as he stated.

David Seymour, called for the defence, said that he had visited Dr. Cohen on behalf of King. He had seen King at dinner in a very poor state of health

[3] THE LANCET, 1930, i., 1255.

and King's wife had asked him later on to go and see the doctor. Witness had asked the doctor if he would call upon King, and had asked him for three certificates, which he had declined to give. He had explained that King had to sign on at 6 o'clock and asked him urgently for a certificate from work to enable a substitute to be found. Witness had said that King was in a very poor state of health and in bed. Dr. Cohen had given him the certificate in question and had charged no fee.

Mr. Hempson repeated the regrets expressed by Dr. Cohen and put in two testimonials to general character from Sir Ewen Maclean and Dr. W. S. Thomson.

After deliberation in camera, the President addressed Dr. Cohen as follows:—

Mr. Cohen: I have to inform you that the Council have given very careful consideration to the charge brought against you, and to the evidence adduced in support of it. They have found that the fact alleged against you in the Notice of Inquiry has been proved to their satisfaction—namely, that the certificate in question was given in a lax and careless manner, and was in fact misleading or improper. The Council regard laxity in the giving of such certificates as a grave matter, which may result in injury to your patients or to others, and worthy of censure on the part of the Council, but, in order that you may have time to reconsider your position in this respect, they have decided to postpone pronouncing judgment on the fact found against you until the May Session of the Council in 1931, when you will be called upon to appear before the Council once more. Before that date you will be required to send to the Registrar the names of two or three practitioners, such as those you have supplied us with just now, who will be prepared to testify to your character and conduct in the interval. In due course you will receive a formal notice of the date when you will be required to attend.

The Case of John McGhee, registered as of Station-road, Galston, Ayrshire, M.B., Ch.B. 1923, U.Glasg., who had been summoned to appear before the Council on the following charge:—

That, being a registered medical practitioner, you on Sept. 8th, 1930, signed and issued a medical certificate of cause of death of Dorothy Elizabeth Cawston, certifying the cause of death as pneumonia, and that you were in medical attendance during her last illness, whereas you had not seen or examined the said Dorothy Elizabeth Cawston, which certificate was untrue, misleading or improper. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The case had been reported by the coroner for the Easington Ward of the County of Durham.

Mr. Harper addressed the Council and pointed out that on elementary principles, Mr. McGhee ought not to have given the certificate, as he had never seen the child. Respondent claimed that, by omitting to fill in the date "last seen by me alive," he had stated that he had not seen her alive. He said that he had filled in "pneumonia" as the cause of death because that had been the opinion of the woman in attendance. Mr. Harper suggested that the real reason for his action had been that he had several times been asked to see the child and had not gone, and, to avoid publicity and reproach, had given a certificate which he had hoped would be sufficiently muddled to slip through.

The respondent, speaking on his own behalf, said that the father of the deceased had never paid the weekly sixpence which, by arrangement, covered medical attendance and drugs for the family. He had deliberately refrained from attending, as the man was in regular work, and had twice explained this to the man. He had known there must be an inquest, but had no information to give the coroner as he had never seen the child. He said he had regarded the certificate as a means of informing the registrar and coroner, as he had indicated that he had never seen her alive by putting a stroke through the printed date in that division. The Registrar had said he could not accept the certificate. Mr. McGhee maintained that if he had wanted to deceive he could have made a better job of it. He had been under the impression that one way to procure an inquest was to return an unsatisfactory certificate.

In reply to the President, he said that he had been in Durham five years and had had dealings with the coroner before. On one occasion he had written a letter detailing the medical history of a patient of his who had dropped dead. The cases had, however, been straightforward, whereas the present case differed in that the girl had never been his patient and the police had sent the father to him for a certificate. He had signed the statement without reading it.

In reply to Mr. Harper, he admitted saying to a messenger from Cawston that he might come to see the child after dinner; it was not true that he had said he would come at once.

After deliberation in camera, the President announced that the Council had found the charge proved to their satisfaction; that they took a very grave view of such conduct but had decided to postpone judgment for 12 months.

CHARGES OF INTOXICATION.

The Case of John Griffith Barrie, registered as of 100, Tulse-hill, Brixton, S.W. 2, L.M.S.S.A. Lond., who had been summoned to appear before the Council on the following charge:—

That you were convicted of the following misdemeanours, viz.: (1) on Nov. 11th, 1925, at the Greenwich Police-court: (*a*) of being drunk whilst driving a motor-car, and were fined 40*s.* and £10 10*s.* costs; and (*b*) of driving a motor-car in a manner dangerous to the public, and were fined £20 and your driving licence endorsed and suspended for the remainder of term; (2) on May 21st, 1928, at the Westminster Police-court, of driving a motor-car in a manner which was dangerous to the public, and were fined £20 and £6 costs (or in default six weeks' imprisonment), licence endorsed and disqualified for six months; (3) on May 21st, 1928, at the Westminster Police-court, of driving a motor-car in a manner which was dangerous to the public, and were fined £20 (or in default six weeks' imprisonment), licence endorsed and disqualified for six months; and (4) on July 22nd, 1930, at the Lambeth Police-court, of being drunk and disorderly, and were fined 15*s.* and 15*s.* costs.

Mr. Barrie attended and was represented by Mr. Pereira, counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors, on behalf of the London and Counties Medical Protection Society. There was no complainant. Mr. Harper, the Council's solicitor, laid the facts before the Council and Mr. Pereira examined Mr. Barrie, who expressed his extreme regret, gave assurances for the future, and said that he had been a total abstainer since July 13th.

Dr. G. K. Reeves and Dr. C. G. Martin testified to Mr. Barrie's abstinence since July and his hard and conscientious work in a large practice. They both lived near him and saw him frequently. Dr. Reeves ascribed his occasional intemperance to overwork.

The President announced that the Council had found the facts proved to their satisfaction, but that, in order to give Mr. Barrie an opportunity of reconsidering his position, they had decided to postpone judgment for a year. Mr. Barrie repeated his assurances of improvement.

The Case of James Rutherford Ratcliffe, registered as of 1, Grange-street, Port Talbot, Glam., M.B., C.M. 1897, U.Glasg., who had been summoned to appear before the Council on the following charge:—

That you were convicted of the following misdemeanours, viz: (1) on March 3rd, 1916, at the County Police-court, Neath, Glamorgan, of being drunk in charge of a motor-car, and were fined 40*s.*; (2) on March 24th, 1919, at the Clerkenwell Police-court, of being drunk, and were fined 10*s.*; and (3) on April 22nd, 1930, at the South-Western

Police-court, of being drunk and incapable, and were fined 1*s.* and 10*s.* 6*d.* costs.

Dr. Ratcliffe appeared in answer to his notice and was represented by Mr. Pereira, counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors, on behalf of the London and Counties Medical Protection Society.

Mr. Harper, the Council's solicitor, laid the facts before the Council. Dr. Ratcliffe had been warned and had twice acknowledged his error. Mr. Pereira called Dr. Ratcliffe as witness on his own behalf. He admitted the charges and expressed his most sincere regret and his intention to abstain from alcohol in future. Mr. Pereira put in two statutory declarations from a doctor and a dentist in Glamorgan, testifying to the respondent's character, and pointed out the lapse of time between the three convictions, and the small fines imposed.

The President announced that judgment would be postponed until May of next year, subject to the usual provisos.

The Case of John Logan Lamond, registered as of 80, Belsize Park-gardens, Hampstead, N.W. 3, M.B., Ch.B. 1916, U.Edin., who had been summoned to appear before the Council on the following charge :—

That you were convicted of the following misdemeanours, viz. : (1) on Nov. 16th, 1926, at Wealdstone (Middlesex) Petty Sessions, of being drunk and incapable, and were fined 5*s.* and 10*s.* 6*d.* costs ; (2) on March 15th, 1927 at Bow-street Police-court, of being drunk in charge of a motor-car, and were fined 30 guineas and 10 guineas costs, or two months' imprisonment in default ; and (3) on July 3rd, 1930, at Bolton (Lancs.) County Police-court : (*a*) of being drunk whilst in charge of a motor-car, and were fined £40 and £4 4*s.* costs, or three months' imprisonment ; (*b*) of driving a motor-car in a manner dangerous to the public, and were fined £1, licence suspended and disqualified for obtaining another for two years.

Dr. Lamond attended in answer to his notice and was accompanied by Mr. Hinde, counsel, instructed by Messrs. Sawyer and Withall, solicitors.

Mr. Harper laid the facts before the Council. Mr. Hinde pleaded that Dr. Lamond was highly strung and nervous, with an impediment in his speech, and suggested that the policeman had been in error. He had only had two or three drinks in a private house, but he was very easily affected by alcohol. Mr. Hinde called Dr. Lamond as a witness on his own behalf ; he promised to abstain from alcohol in future.

The President announced that judgment would be postponed for 12 months.

The Case of Francis Patrick Kennedy, registered as of 111, Cambridge-road, E.1, L., L.M. 1913, R.C.P.Irel., L.M. 1913, R.C.S. Irel., who had been summoned to appear before the Council on the following charge :—

That you were convicted of the following misdemeanours, viz. : (1) on April 20th, 1925, at the Stratford Petty Sessions : (*a*) of being drunk in charge of a motor-car, and were fined 40*s.* (or in default 31 days' imprisonment) and 10*s.* 6*d.* doctor's fee ; and (*b*) of driving in a dangerous manner, and were fined £5, or in default 31 days' imprisonment ; (2) at the County of London Sessions commencing on Oct. 7th, 1930, of being drunk while in charge of a motor-car, and were fined £25 and £25 costs, licence suspended and disqualified for holding a licence for three years.

Dr. Kennedy attended in answer to his notice and was accompanied by Mr. Oswald Hempson, solicitor. Mr. Harper laid the facts before the Council and said that Dr. Kennedy had pleaded "not guilty" to the charge of dangerous driving.

Mr. Hempson called Dr. Kennedy as a witness on his own behalf. He said that he had been reversing his car in order to turn and had driven on to the pavement in this way. He had sold his practice because of the publicity attendant on this case ; he repeated his sincere regrets and undertakings for the future. Mr. Hempson pointed out the long interv between the offences, and said that both were la at night when the doctor was off duty.

The President announced that the Council ha decided to postpone judgment for 12 months.

The Case of Ralph Johnston Tait, registered as of 4 Queen's-road, Leicester, M.B., Ch.B. 1913, U.Edin., D.P.H R.C.P.S. Edin., and R.F.P.S. Glasg. 1920, who had be summoned to appear before the Council on the followi charge :—

That you were convicted at Leicester of the followi misdemeanours, viz. : (1) on Nov. 15th, 1926, of bei drunk and incapable and were fined 10*s.* ; and (2) April 19th, 1930, of being drunk in charge of a motor-car, a were fined £10 and 10*s.* special costs.

Dr. Tait attended in answer to his notice, but w not accompanied by counsel or solicitor. Mr. Harp laid the facts before the Council and Dr. Tait expresse his great regret, and said that he was peculiar susceptible to alcohol. He promised to be absolute teetotal in future.

The President announced that judgment would postponed for 12 months.

The Case of James Gordon Bell, M.C., registered as Ballochmyle House, Dunfermline, L.R.C.P. Edin. 19 L.R.C.S. Edin. 1914, L.R.F.P.S. Glasg. 1914, M.B., Ch. 1914, U.Edin., who had been summoned to appear before t Council on the following charge :—

That you were convicted of the following misdemeanou viz : (1) on Feb. 21st, 1928, at the Sheriff Court, Stirli of driving a motor-car recklessly while in a state of intoxi tion, and were fined £15, licence suspended until date expiry, and prohibited from obtaining another for two ye thereafter ; (2) on May 5th, 1930, at the Sheriff Cou Dunfermline, of driving a motor-car negligently and drivi said motor-car against a tramway car, and were fined current licence suspended, and disqualified from obtaini another for five years from expiry of current licence ; (3) May 17th, 1930, at Edinburgh Police-court, of being dru and incapable, and were fined 15*s.* or ten days' imprisonme

Dr. Bell did not attend and Mr. Harper, layi the facts before the Council, said that he had had gre difficulty in finding him He had eventually receiv a reply from Mrs. Bell, who had said she did n know where her husband was and had not heard fr him for some time. She had suggested an addr which had at last found the doctor, who had repli saying he would be present. Yesterday, Mr. Harp had received a letter from a firm of Edinbur solicitors who had again said that Dr. Bell would present and had sent a written defence. A telegra handed in at Dunfermline, at 12.45 that day, h said that Dr. Bell could not attend owing to illne and asked for postponement. Mr. Harper, howev doubted the bona fides of this belated excuse. T defence pleaded overwork and the results of Dr. Bel war service, for which he had received the Milita Cross and a 60 per cent. disability pension. T President announced that the facts had been prov to the satisfaction of the Council, which direct Dr. Bell to attend for judgment at the May session.

Committee Business.

The Registrar had reported at the meeting of t Executive Committee held on Nov. 24th, 19 that a letter had been received from the Univers of Melbourne drawing attention to the fact that M.S. degree was not included in the list of registra qualifications appearing on page *c* of the Medi Register.

The following resolution had been adopted by t Executive Committee :—

Any person holding the Degree of M.S. of Melbou University shall be entitled to register this degree as additional qualification in the Medical Register.

The Council adopted the resolution.

EXAMINATIONS AND INSPECTIONS.

The report of the *Education Committee* was submitted by Sir Humphry Rolleston, who pointed out that the discussion with the Conjoint Board in Ireland, on the subject of the practice of passing by compensation the examination in general education, was still under discussion. The Queen's University of Belfast had announced that from next year a pre-registration examination in physics and chemistry would be held in October, in order to comply with the recommendations of the Council. Prof. R. P. Johnston, seconding the adoption of this report, pointed out that the standard of the pre-registration examination was much lower than that of the matriculation examination in these subjects, but that there seemed to be no way of exempting from the October examination students who had passed the matriculation.

The report of the *Examination Committee* was submitted by Sir Norman Walker. In accordance with the recommendation of the Committee last May, the reports of the visitors to the examination in medical jurisprudence and public health were published as an appendix, none of the bodies visited having raised any objection to publication. Meanwhile, the visitors had been inspecting the examinations in medicine, surgery, and midwifery, but their reports on these subjects were confidential until the consent of the bodies visited had been received. The inspector in midwifery had reported that the examination in midwifery at the University of London was "not sufficient." It had long been the practice for the inspectors to make a second visit if they were unable to report satisfactorily at one visit, but as this practice was not clearly expressed in the standing orders, the Committee laid before the Council the recommendation: "That the Committee instruct the inspector in midwifery to make another inspection of the examination in that subject held by the University of London in June, 1931."

Speaking on this subject, Dr. H. L. Eason objected to asking for a second inspection when the reason for the insufficiency was not before the Council. In reply, the President said he thought that he might state definitely that the reason was the absence of any clinical examination, a form of test which was now almost universal.

Another part of the same recommendation instructed the inspector in surgery to make another inspection of the examination of the Society of Apothecaries of London, as he had been unable to pronounce their examination sufficient. This raised an interesting point, because the assistant examiners for the Society had been for many years appointed by the Medical Council itself. The point, therefore, arose whether the insufficiency should be dealt with between the Council and the Society or between the Council and its own assistant examiners, whose duty it was under Sec. V. (2) of the Medical Act, 1886) to "secure at the said examinations the maintenance of such standard of proficiency . . . as is required." Lieut.-Colonel C. T. Samman, speaking on this point, assured the Council that the governing body of the Society were with him in desiring to see their examination attain as high a standard as possible; they would meet the Council in any way they could.

The third recommendation put forward by the Education Committee was: "That the President be requested to appoint a deputy visitor to visit and report on the pre-registration examination held by the licensing bodies." Mr. K. W. Monsarrat objected to the term "pre-registration examination," because many licensing bodies accepted other examinations in lieu of a pre-registration examination. He was anxious that these too should come under the ægis of the Council's inspection. The President made it clear that the acceptance of other examinations rested entirely with the licensing body; that the registrar had no power to accept any examination unless it was already accepted by a licensing body, and that it would be possible for the inspector to inquire what examinations were accepted, and to report on their scope. Sir William Taylor was anxious to have some report on the courses of study leading up to the examination, but the President said that the Council had no power to inspect pre-registration teaching. Prof. A. F. Dixon drew attention to cases where the pre-registration examination was the only examination in chemistry and physics held in a teaching centre. Sir William Taylor asked whether it would be possible to find one visitor competent to inspect both physics and chemistry, and the President replied that, judging by previous experience, it would be possible.

THE PHARMACOPÆIA.

The President introduced the report of the *Pharmacopœia Committee*. The number of copies of the British Pharmacopœia sold in the year ending Nov. 21st, 1930, was, he said, 1733, a slight decrease on the previous year. The Pharmacopœia Commission had continued its work of writing and revising monographs, and a revision of posology had been completed. The Pharmacy Subcommittee were engaged in devising formulæ for new preparations, and a new edition of the British Pharmaceutical Codex was in preparation. The Commission had established friendly relations with the Committee of Revision of the United States Pharmacopœia. The Pharmacopœia Committee had approved the inclusion in the new Pharmacopœia of monographs on insulin and irradiated ergosterol.

MATERNAL MORTALITY.

The Council discussed the recommendations which a joint committee of the Education and Examination Committees had prepared after considering the interim report of the Departmental Committee on Maternal Morbidity and Mortality, which contains the observations of that committee on the Council's recommendations adopted in 1923, and certain recommendations for the education of the medical student in obstetrics. The Council, after making a few verbal alterations, adopted the report of the joint committee, and directed that copies of the proposed communication be sent to the Lord President of the Privy Council, and to each of the licensing bodies for comment.

The communication, as amended, is as follows:—

The Council, being fully convinced of the need for progressive improvement in the teaching of obstetrics, readily complies with the request of the Privy Council to give the Report of the Departmental Committee on Maternal Mortality and Morbidity prompt and favourable consideration, and appoints a joint committee consisting of all the members of its Education and Examination Committees to consider and to present a report thereon to the Council during the present session.

It is within the knowledge of the Council that some of the licensing bodies are not successful in ensuring that all the present recommendations of the Council in respect of the training of students in midwifery are in fact being carried out.

In connexion with this it should be borne in mind that the decennial inspection of the three final or qualifying subjects is now in progress, and that the reports of the inspector of midwifery hitherto received contain much valuable information as to the extent to which the recommendations of the Council (1923) are observed by the different licensing bodies. It is in the opinion of the Council desirable to await the

completion of this inspection before further or amended recommendations are issued by the Council.

With the proposal to concentrate the teaching of obstetrics, gynæcology, and closely related subjects into a continuous period of six months the Council is favourably impressed.

The proposal to increase the duration of residential study in a maternity hospital or maternity ward to two months is approved by the Council, and where practicable should be carried out forthwith.

When the Council is satisfied that all the licensing bodies are able to ensure the provision of 20 obstetric cases for each student, the figure specified in the existing recommendation, the question of increasing this number to 30 can and will be considered by the Council. At present the Council is inclined to lay more weight on a longer period of residence that on an increased number of obstetric cases.

The Council in its present recommendation (1923) has recognised the importance of adequate instruction in ante-natal care, and welcomes any proposal which will increase the facilities for such instruction now accessible to students.

Pending the completion of the inspection of the qualifying examinations in midwifery, the Council considers it advisable that the several licensing bodies should have an opportunity of considering and of commenting upon the recommendations of the Departmental Committee, having special regard to the practicability of introducing all or some of the changes proposed into the medical curriculum.

Recommendation.—That a copy of this report be sent to each of the licensing bodies, with a request that before May 1st, 1931, its comments thereon should be sent to the Medical Council.

The Council also directed, on the motion of Dr. Brackenbury, that a letter should be addressed to the Minister of Health requesting that students be admitted to the new maternity wards which will be available to local authorities under the Local Government Act, 1929.

The joint committee reported that they had not yet been able to devote adequate time to their consideration of the report of the Society of Medical Officers of Health on The Place of Preventive Medicine in the Medical Curriculum, which they describe as "an important and interesting document."

MEDICINE AND THE LAW.

The Dog in the Car.

A RECENT decision of the Court of Appeal will have interested the many medical practitioners who are owners both of motor-cars and dogs. One evening, 18 months ago, a man parked his saloon car with its back to the kerb in a street at the rear of a well-known shop in Oxford-street. Inside the car was his Airedale dog. As another man walked past the back of the car, the dog (which was said to have been barking and jumping about in the car) smashed the glass panel. A splinter of glass entered the eye of the passer-by; operation was necessary, and four days later the eye was removed. The victim of the accident claimed damages against the owner of the dog, alleging various forms of negligence. The defendant, he argued, was at fault in parking his car where he did, in placing the dog inside, in leaving the car and dog unattended on the public highway, and in failing to tie the dog up in a safe and suitable manner. The case was tried before Mr. Justice Talbot and a common jury, and the plaintiff was awarded £2000. The Court of Appeal has reversed the decision, and has ordered judgment to be entered for the dog-owner. Animals, said Lord Justice Scrutton, may be divided into two classes. There are the wild animals, like tigers and gorillas, which are likely to be dangerous in themselves; a man taking out such an animal is responsible for the damage which it does. In the second class come the animals like dogs and cats, which are ordinarily kept in comparative freedom. There is no obligation to keep the latter class under control; unless the owner is aware that the dog cat has some vicious tendency, he is not liable f the damage it may do. This particular Aireda terrier, as Mr. Justice Talbot had said, had a hither blameless character; the owner therefore was n responsible for the accident. Hundreds of peopl said Lord Justice Scrutton, leave dogs in motor-car and nobody had ever heard of such an accident befor The defendant left his car with an apparently perfect well-behaved dog inside; something then happen which had never happened before. This was n negligence; there was no evidence on which t jury could find for the plaintiff.

Motor-car Insurance.

In another case concerned with motor-cars t Court of Appeal has upset a decision of the cou below. The owner of a car was insured under policy which contained a not too clear clause coveri the use of a substituted car. Having occasi to require repairs to the car, and finding that the co of the repairs would be considerable, the motor decided to buy a fresh car of the same type, handi over the old car in part payment. He met with accident in the new car and he sued on the polic The judge at trial took the view that the new c of the same type could be deemed a substituted c within the cover of the policy. The Court of App has now decided that this interpretation is wron The motorist was insured in respect of a particul car and, when he gave up the ownership of it, ceased to have an insurable interest under the polic

It is possible that this, and the preceding ca will be taken to the House of Lords. If so, the l word has not yet been said. The fact that a Hi Court case may thus undergo two successive revisio has been commented on lately by correspondent who think that litigation is too slow, too dear, and t uncertain. If there is a strong Court of Appeal, the critics remark, a further appeal to the House Lords is altogether unnecessary.

Arsenic in Sweets.

Remarkable evidence was given at Stoke-o Trent during criminal proceedings against two m respectively described as a sugar boiler and a sw manufacturer. The actual charge upon which th were convicted was that of powdering sweets w arsenic. According to the prosecution the Food a Health Department of the Stoke City Council beca aware early in September of an outbreak of illn due to the eating of sweets. The sweets were fou to be heavily impregnated with arsenic. On Sept. every bottle of sweets made by this particular ma facturer was seized and sealed to prevent furth distribution. The sugar boiler had premises Tunstall, where a box was found containing nea a hundredweight of arsenic. He said he hones believed it was French chalk. The sweet manufactu had said he was short of dusting powder and powder from the box was furnished. It appea that in the yard near the sugar boiler's premi there were works where enamelling was do Mr. A. E. Johnson, the city analyst, said the fi sweets he analysed contained grs. 77 of arsenic pound; another sample of cough sweets contai grs. 82. The maximum permissible was gr. 1/100 Of two samples of dusting powder, one contained per cent. of arsenic, the other consisted entirely arsenious oxides. Fortunately, no deaths resulte the poison being in such large doses, the consequ vomiting seems to have eliminated it before it absorbed. The magistrate, in fining the accu

£25 and £15 respectively, said that the sugar boiler had not taken the slightest trouble to find out if the powder was fit for the purpose. Even if the man thought it was a proper powder previously used in his own business, it was grossly careless to use it without some precaution to see whether it had been tampered with. There was no substantial ground for thinking it to be French chalk. As for the sweet manufacturer, if a person, without the slightest precaution, used material which was injurious to health, and intended that, when the operation was completed, the article should be sold, that was an offence.

Had a civil action been brought against the two defendants for damages, they could hardly have avoided an adverse judgment. There was a strong prima facie case of negligence; in the legal phrase *res ipsa loquitur*. Had death resulted and been followed by criminal proceedings for manslaughter, it would, of course, have been necessary to prove a higher degree of negligence than in a civil action. One may expect that some of our enterprising municipalities will now seek powers by Local Act to keep their medical officers in close touch with the premises where sweets are manufactured. The present powers of inspection are inadequate if the local authority does not know what premises are being thus used. The provisions in many Local Acts for the registration of manufacturers and premises used for the purposes of ice-cream, potted and preserved meat, food made from fish, &c., could, perhaps, be extended.

The incident at Stoke-on-Trent will stimulate fresh criticisms of the ease with which arsenic can be handled and obtained. It is scandalous that a box containing a hundredweight of arsenic could be left about without any supervision or indication of its nature. Local Acts (for example, Section 50 of the recent Manchester Corporation (General Powers) Act) are beginning to include penalties on people who fail to take proper precautions to prevent danger from the presence of disused petroleum vessels in premises. It seems reasonable to deal with potential risk of death from poisoning as drastically as with the danger of death from fire.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

DEATH OF PROF. FUCHS.

At the age of 79 Prof. Ernst Fuchs, one of the best-known ophthalmologists in the world, died on Nov. 22nd after an attack of angina pectoris. He was a man of unusual qualities as student, teacher, and healer. A pupil of the famous surgeon Billroth, Fuchs early turned his attention to the new field opened up by the invention of the ophthalmoscope. He became assistant to Prof. Arlt, then the leading ophthalmic surgeon in Europe, and soon was called to Liége in Belgium to take charge of the eye department. There he published his famous book on "The Etiology and Prevention of Blindness." In 1885 he returned to Vienna to succeed Prof. Jäger, and in the small eye clinic of Vienna, as it appeared at that time, originated the series of clinical, physiological, and histological discoveries which was to make the clinic a Mecca for the specialty. Fuchs was the true builder of ocular morbid anatomy. He was an unsurpassed teacher, and his Text-book on Diseases of the Eye has become, so to say, the Bible of ophthalmology. It has been translated into all the important European languages, and also into Japanese and Chinese, and patients and surgeons from every continent flocked to his clinic. He was called to China, to Egypt, India, Russia, and Spain to operate there. When, at the age of 70, he retired from his clinical post, he took to travelling all over the world, and even then made important contributions to our knowledge of foreign eye diseases. He turned his attention to the infections of oriental countries, and in his eighth decade studied conditions in Egypt and Asia Minor. As a teacher of general practitioners, Fuchs imbued all his pupils with the necessity of commanding sufficient skill to treat disorders of the anterior part of the eye. The other conditions, he taught, should best be handed over to the specialist.

DISSECTING-ROOM MATERIAL.

The problem of obtaining enough bodies to enable students in the first two and a half years of the medical curriculum to do all the necessary dissecting work has for several years been very serious here. Formerly the regulations of the hospitals were sufficient to secure an adequate supply. But now not only has the number of medical students more than doubled (compared with the years 1900–10), but the number of suitable bodies has much diminished. The law stipulates that all corpses not claimed by their relatives or friends belong eo ipso to the Anatomical Institute, if the patient dies in one of the State hospitals. Of late, however, it has become the custom that pious societies of all creeds represented in this country should take care of hospital patients reported to be friendless, and claim their bodies for a religious interment. This claim must be complied with. These societies work principally in Vienna and Graz, where there are large universities. Therefore it has become the routine practice that the provincial State hospitals supply the dissecting institutes with bodies not claimed. Furthermore in every case of suicide there is a partial dissection in the forensic institute, and if not claimed the body is usually sent to the "Anatomy" and there stored away. The law permits the sale or bequest of one's own body during lifetime, but this is rarely done. However, the vaults of the institute now contain enough bodies to keep it running for two years if the restriction of first-year medical students, as now in force, is adhered to. The restriction consists in admitting for dissecting studies only those students for whom places are available (about 250). In the first line, Austrian-born students are admitted, and only if all these are placed can foreigners be taken.

THE CAMPAIGN AGAINST TUBERCULOSIS.

The Ministry for Public Health in Austria has recently published an account of the institutions engaged exclusively in fighting tubercle. They fall into four groups—welfare centres, sanatoriums, convalescent homes, and tuberculosis hospitals. At present there are 87 welfare centres, each served by two or three competent lung specialists, assisted by one to four nurses. The object of these centres is to discover cases of tuberculosis, to help the patients to get suitable treatment, and to look after their health after treatment in one of the special institutions. The nurses follow up the cases at their homes and advise the family in matters of hygiene and prophylaxis. The 45 special sanatoriums are under the supervision of the Board of Health; 33 of them, with 4970 beds, are intended for tuberculosis of internal organs; and 12, with 942 beds, for surgical cases. It

may be noted that in the first group we find 621 beds available for men only, 1542 for women only, and 920 for children only; the remainder can be used as required. In the surgical group, 72 beds are for men, 88 for women, and 497 for children, whilst the remaining beds are in hospitals, where they are used as necessary. The number of convalescent homes is also 45. They contain 5120 beds between them, of which 168 are intended exclusively for male adults, 519 for female adults, 1360 for male adolescents, 705 for female adolescents, and 1025 for children. The rest are for both sexes and all ages. Finally, we have the hospitals for tuberculous patients—109 of them, with a total of 4017 beds. Of these, 3069 are open for pulmonary tuberculosis, and 948 for surgical cases. These hospitals are partly private (run on the profit system), but most are owned and kept by the State or the county councils.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

NIGHT NOISE.

My recent account of the action of the Touring Club of France in appointing a special noise commission has led some of my readers to assume that Paris is a noisy city. There is, in fact, little probability of a *brigade du silence* coming into effect. For some time past all police agents in the city have been entitled to put a stop to nocturnal noise, and between 1 and 7 A.M. automobiles which transgress the permissible limit of nocturnal noise are liable to prosecution. Paris is, in fact, becoming increasingly quiet during the hours of night.

THE CLOSING OF BROTHELS.

Two doctors of the sanitary service of Lyons, Dr. M. Carle and Dr. Léon Lacassagne, have set out at length in the *Siècle Médicale* what they regard as the moral consequences of the suppression of the *maisons closes* or *maisons de tolérance*. Although sexual indulgence may have become more difficult for groups which they neatly summarise as *le passant, le troubade, l'ouvrier*, it is not less apparent to them that the torrent of desire diverted from its canalised channel has overflowed its banks, submerging the frail virtues encountered on its passage. From the moral as well as the sanitary side they regard the benefits of the recent legislation as more apparent than real. There may be fewer segregated women, but there will be more prostitution in the ranks of the small employees; venereal disease in clandestine form is increasingly shown by figures both public and private. Our authorities, they say, cannot afford to omit the police supervision of prostitution. A little city like Grenoble may close its brothels and dismiss its local police, but a Congress resolution is little more than a political gesture. What applies to the small town cannot be transferred to the large, and the experience of Strasbourg may have a lesson for other urban centres. If the brothel is dying it is not the law that is killing it; in Carle and Lacassagne's opinion it is simply overwhelmed by the competition of the *maisons de rendezvous*. Prostitution is the most complicated of our social problems. Paris has its closed houses, but its streets are fairly clean. Parisians are not unaware of the little flats round Leicester-square and the solicitation at street corners. If the Londoner retorts that many of those concerned are of French nationality, he may be reminded that the Paris *police des mœurs* does not accept foreigners.

THE LATE PROF. GLEY.

You have noted the death of Prof. Gley, one of our leading physiologists, after surgical operation. He succeeded Marey at the Collège de France, and devoted his whole life to physiological research and especially to endocrinology. He was not only a great scientist, but he had an exquisite knowledge of classical and modern literature. His speeches at medical meetings were awaited with pleasant anticipation, for he could be both passionate and coldly intelligent, and his delivery was easy and audible.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 22ND, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 116 (last week 107); scarlet fever, 2297; diphtheria, 1593; enteric fever, 28; pneumonia, 828; puerperal fever, 38; puerperal pyrexia, 129; cerebro-spinal fever, 13; acute poliomyelitis, 12; encephalitis lethargica, 16; dysentery, 8; ophthalmia neonatorum, 96. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 25th–26th was as follows:—Small-pox, 221 under treatment, 3 under observation (last week 186 and 1 respectively); scarlet fever, 1938; diphtheria, 2208; enteric fever, 15; measles, 82; whooping-cough, 107; puerperal fever, 24 (plus 9 babies); encephalitis lethargica, 120; poliomyelitis, 1; "other diseases," 47. At St. Margaret's Hospital there were 11 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 40 (0) from measles, 6 (0) from scarlet fever, 10 (2) from whooping-cough, 30 (3) from diphtheria, 71 (12) from diarrhœa and enteritis under two years, and 49 (6) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London were reported from Stoke-on-Trent and South Shields. Measles accounted for 13 deaths at Hull, 5 at Bristol, 4 at Liverpool, 3 each at Birmingham and Swansea. Liverpool reported 5 deaths from diphtheria. Fourteen fatal cases of diarrhœa occurred at Liverpool, and 6 at Birmingham. There was no death from small-pox during the month of October last in the areas outside the great towns.

The number of stillbirths notified during the week was 257 (corresponding to a rate of 43 per 1000 births), including 53 in London.

DEATH FROM SMALL-POX.

A fatal case of small-pox reported from Wood Green was that of a man, 50 years of age, employed as a teacher of English to foreign students in an institution in London. He complained of sore-throat on Nov. 22nd; the next day he was much out of sorts with pain in the back, limbs, and head. On Nov. 24th he called in a doctor who found a temperature of 102° F. and symptoms suggesting a severe attack of influenza. The following day he was rather worse, rambling at times in his speech. On Nov. 26th a profuse papular rash appeared on the face, trunk, and, to a less extent, on the limbs; this was suggestive of small-pox but not typical in character or distribution. As the patient was then extremely ill, Dr. M. Manson, medical officer of health, who saw him, advised removal to South Wharf as a suspected case of small-pox. On admission there he was transferred to the Joyce Green Hospital, Dartford, where symptoms of cerebral trouble became very definite, and he died 24 hours later. Permission for post-mortem examination was refused. The cause of death entered on the certificate was: (1) cerebral thrombosis; (2) small-pox. The man had been vaccinated in childhood but probably not since then.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of three counties :—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Lancashire .. (1,811,700)	14·1	14·0	0·76	1·41	3·4	2·5	84/—	44	4·9
West Riding of Yorkshire (1,528,800)	16·7	13·6	0·87	1·28	3·0	2·3	89/38	53	5·2
Essex .. .. (1,110,400)	16·3	11·2	0·76	1·36	2·1	2·1	53/—	26	3·2

Registered stillbirths per 100 live births : Lancashire 4·9, West Riding —, Essex 3·4.

Lancashire.

Dr. J. J. Butterworth's report contains, as usual, an enormous mass of detailed information, mostly in tabular form, with respect to the 19 municipal boroughs, 81 urban districts, and 19 rural districts which make up the administrative county. Largely owing to the influenza epidemic there were nearly 4000 more deaths than in the previous year. The excess deaths were chiefly attributed to influenza, heart disease, pneumonia, and bronchitis ; and the only age-periods which showed no excess were from 5 to 25 years. Little use has been made of the Housing (Rural Workers) Act. Up to June 30th, 1930, £1536 in grants had been promised in respect of 16 dwellings and £936 had actually been paid in respect of 10 dwellings. During 1929, 576 outside complaints of tuberculous milk were received and in each case a veterinary surgeon retained by the county council and a sanitary officer visited the farm. The facts found were reported to the county agricultural department and the ultimate result is not given. There are about 7224 dairy farms and the number of cattle is approximately 95,000. The clean milk competition promoted by the County Milk Recording Society, assisted by the public health department, only attracted 10 competitors. The number of licences issued for Certified milk by the Ministry is 5.

Of 4993 samples examined under the sale of Food and Drugs Acts, 2·8 per cent. were returned as adulterated. There was a drop in the percentage adulteration of articles other than milk and a slight increase in milk adulteration. Mr. G. D. Elsdon, the public analyst, commenting on the claim that the percentage of fat is seriously diminished when the cows are first put out to grass, shows that the reduction is only slight. Of over 48,000 samples of milk examined during the years 1913–29, the average composition for the year was 3·68 per cent. of fat and 8·91 per cent. of solids-not-fat. When the composition is examined month by month it is found that the average fat percentage for April is 3·63 ; for May, 3·59 ; for June, 3·55 ; for July, 3·57 ; for August, 3·66 ; and for September, 3·75. As is well recognised, the assumption that milk contains added water is based on its content of solids-not-fat. In 1921 Hortvet (U.S.A.) devised an apparatus for the detection of added water in milk, which depended on the constancy of the freezing-point of genuine milk. Mr. Elsdon has been investigating the reliability of the Hortvet apparatus during the year and up to the present his work confirms its value. Of 58 samples of water examined as to potability, 4 out of 10 from shallow wells were unsafe or doubtful and 2 unfit ; 11 out of 16 from deep wells were classed as unsafe or doubtful ; 2 out of 4 from springs, 1 out of 3 from streams, and 1 out of 14 from an upland surface source were also put in the same category.

There were 406 notifications of small-pox and 3 deaths. Scarlet fever cases numbered 6205 and the deaths 34. At Oswaldtwistle two children were removed to hospital leaving two at home. After six weeks in hospital the patients returned home and the two other children contracted the disease. As a result the local medical officer of health adopted the eucalyptus oil method and up to now has had 86 cases without a secondary case. At Preston (rural) four families with the same milk-supply were attacked. When the farm was visited a girl was found, who was desquamating, with a typical scarlet fever tongue, following a sore-throat, and her brother had been ill seven days previously. In Prestwich there was a school epidemic caused by scholars attending school whilst undergoing very mild attacks. The cases of diphtheria numbered 1620 and the deaths 120, giving the high case-fatality of 7·4 per cent. At Wigan (rural) an outbreak of enteric was attributed to a carrier, and an outbreak at Oswaldtwistle to drinking water from a stream grossly polluted with excretal matter. In 1924 there were 299 notifications of encephalitis lethargica and 103 deaths. The numbers have slowly declined and in 1929 there were 88 notifications and 94 deaths. The notification figures for the last ten years evidently underrate the number of persons affected. There was a progressive decline in the county death-rate from pulmonary tuberculosis, from 0·77 in 1922 to 0·58 in 1928, but last year there was a set-back to 0·60.

Twenty-three years ago 83 per cent. of the midwives were untrained ; now, 87·3 per cent. are trained. The county council is the local supervising authority for midwives in the whole administrative county, and directs the maternity and child welfare work in 79 out of the 119 districts ; it conducts one antenatal clinic at Litherland and contracts for the use of three antenatal clinics at Widnes, Chorley, and Eccles. The council also arranges for the use of 20 maternity hospitals and for the admission of antenatal cases to hospitals at Blackburn, Burnley, Liverpool, and Fulwood. The orthopædic scheme has been extended by the inclusion of one county borough, four boroughs, and three urban districts. 245 crippled children were admitted to Biddulph County Council Hospital, where 202 remedial operations were performed. The out-stations treated 2513 children.

West Riding of Yorkshire.

Dr. T. N. V. Potts, who presents the report, did not take over the duties of county medical officer until 1930. Dr. J. R. Kaye retired after 33 years' service in June, 1929, and Dr. P. L. Sutherland was acting medical officer for the remainder of the year.

The influenza epidemic showed its effect on the mortality from heart and respiratory diseases and exacted a toll especially in the earliest and later age-groups. Infant mortality was 27 higher than in the previous year. The general death-rate was the highest recorded since 1919. Dr. Potts thinks the campaign against tuberculosis will be much strengthened by the provision of the new sanatorium of 300 beds at Scotton Banks and the installation of seven X ray plants at the principal dispensaries. As the result of continued trade depression a definite impairment in the nutrition of mothers and children attending the centres was noted and greatly increased quantities of dried milk were issued. A serious epidemic of enteric fever was recorded at Honley. There were 27 cases with six deaths, and the origin of the outbreak appeared to be connected with the contamination of wells by leakage of sewage into an old culvert. Dr. Potts appeals to all local authorities,

who have not yet done so, to adopt by-laws for smoke abatement in order that there may be uniformity in administration throughout the Riding. Some antenatal work is in operation at about half the child welfare centres, and Dr. Potts suggests that there should be a few centres with more complete equipment or maternity homes with an antenatal department manned by specialists of recognised consultative standing to which difficult cases could be referred from the ordinary centres.

Essex.

Dr. William Bullough says the death-rate was the highest since 1919, the increased mortality being largely due to influenza, diseases of the respiratory system, and heart disease. The infantile mortality only showed an increase of two. The new sanatorium at Black Notley (184 beds) was opened by the Minister of Health on April 26th, 1930, and X ray facilities have been extended and fully utilised. There has been some difficulty in maintaining a full staff of health visitors during the year. The care of the crippled children has been furthered by the appointment of a whole-time orthopædic masseuse.

The 1929 clean milk competition was limited to farms which had never received an award, with the aim of extending this educative influence to new entrants. There were 17 competitors. The county council have passed resolutions in favour of amending the nomenclature of designated milks, and of a penalty for the sale of milk which does not conform to a prescribed standard of cleanliness. The samples of milk examined for tubercle were 166 with 15 positive. The percentage of 9·6 compares with 7·0 for the previous years. Dr. Bullough thinks the effort to deal with unfit houses is meeting with more success. Some of the sanitary authorities are considering the provision of houses within the means of the lowest paid worker. Several old and derelict cottages have been most successfully renovated under the Housing (R.W.) Act, 1926. Up to December, 1929, the number of cottages reconditioned under this Act was 104.

The low rainfall of the first nine months of the year drew special attention to water-supplies. Twenty-one per cent. of the parishes in rural districts have no public supply and depend upon shallow wells, rainwater, springs, and ponds. The public supplies in 6 parishes failed wholly or partly and in 23 parishes were depleted, whilst in 244 the supply was maintained. It is hoped that an improvement will result from the power given to the county council under the Local Government Act, 1929, to contribute to the expenditure by local sanitary authorities on water-supplies.

It is considered that the nuisance caused by the dumping of London refuse on the northern bank of the Thames has reached a more hopeful stage. It is 20 years since Dr. J. C. Thresh made his first complete investigation and report on this matter.

MENTAL HOSPITAL REPORTS.

Of the two KENT COUNTY MENTAL HOSPITALS that at BARMING HEATH had 1923 patients in residence at the end of last year and there is need for further accommodation, preferably a new admission villa. Much valuable room is still occupied by mental defectives and old chronic cases who would be better off elsewhere. The recovery-rate was 32·2 per cent. and 74·1 per cent. of the recoveries took place after less than a year's treatment. The death-rate was 7·7 per cent. There were two cases of erysipelas and eight of dysentery, and a small epidemic of influenza in the spring. There has been a great increase in the work of the occupations department, and on an average 65 per cent. of the men and 90 per cent. of the women are engaged in some kind of work. A new occupations centre for women came into use last spring and the movement is more than self-supporting, the profits serving to provide trips to the sea, the Zoo and the circus, and visits to town and picture theatres. Parole is freely given. Installation of electric light is under consideration. Fifteen male nurses work on the male side and 41 attendants and 46 nurses are certificated or registered. A proposal is on foot to open an out-patient clinic at the hospital. There were 1375 patients at the CHARTHAM DOWN HOSPITAL at the end of last year and there also the question of accommodation is becoming acute. Mental defectives are still cared for in the hospital. There was a severe epidemic of influenza in the spring with 30 deaths. Although vigorous malarial treatment is given for general paralysis, many of the cases are admitted so late that the results are disappointing. Tryparsamide bismuth, the Starke treatment, and "Sulfosin Leo" have been tried, with varying success. An investigation on blood pressure has not revealed any relation between the readings and mental disorder. A number of patients who did not seem to have benefited from their food are being treated with insulin with excellent results, but collosal calcium has not given any appreciable benefit in epilepsy. The recovery-rate was 36 per cent. and the death-rate 11 per cent. Parole is used extensively and it is hoped to have wireless in all the wards by next Christmas. The pathological department carried out a large number of routine investigations and an operating theatre is in course of construction. Craft work and drill classes are held twice weekly by voluntary helpers. Plans for a nurses' home are under consideration; 50 male and 27 female nurses are certificated or registered. A consulting ear, nose and throat specialist has been appointed to visit fortnightly.

The CITY OF LEICESTER MENTAL HOSPITAL at WEST HUMBERSTONE had 986 patients on its books on March 31st last. The recovery-rate for the year was 40·7 per cent. and the death-rate 6·6 per cent. Malarial treatment for general paralysis is being continued. There were seven cases of dysentery and one of typhoid. Two enteric carriers were found and in one the gall-bladder was removed to clear up the condition. In addition to a number of routine examinations, the laboratory has investigated the Vernes test and report in favour of it, as being less liable to human error than the Wassermann. The positive Wassermann appears to be more reliable than the positive Vernes, but the negative Vernes more reliable than the negative Wassermann. Parole has been given to more than half the men patients and nearly half the women, and leave of absence granted very frequently. Although there is no organised system of occupation, 71 per cent. of the patients have been usefully employed. The visiting dentist carried out 390 operations. The amount of sedative drugs given has been greatly reduced during the last two years and there appears to be no doubt that patients are better without them. All the nurses are expected to enter for the State examinations; three of them were successful last year, bringing the total to 50 certificated or registered.

MENTAL DEFECT.

The illustrated report of the LANCASHIRE AND CHESHIRE SOCIETY FOR THE PERMANENT CARE OF THE FEEBLE-MINDED records a happy and uneventful year. There are now 101 women and 36 girls, 140 men and 89 boys in the colony. There was one death—an imbecile woman of 35 from very rapid consumption. The report observes that there is nothing in particular to note about the women except the accidental discovery that they had a great dislike to being more than 30 years old! In consequence a special expedition and extra Christmas presents were provided for inmates over that age. The day school is attended by 81 boys and 36 girls. The health was excellent throughout the year and the only infectious illness was mild epidemics of whooping-cough and chicken-pox, one case of measles, and one of German measles. Two girls suffering from phthisis are isolated in an outdoor hut.

CORRESPONDENCE

PIGMENTATION AND DE-PIGMENTATION.

To the Editor of THE LANCET.

SIR,—In a paper given to the Physical Society in 1919 Prof. R. W. Wood demonstrated the use of some black glass which he had invented, which cut out all but a small part of the ultra-violet radiation from an ordinary mercury lamp. Prof. Wood was kind enough to give me a few samples of this glass, and the appearance of people in this beam of invisible radiation seemed striking enough to warrant further observation. In 1920 Dr. Mottram and I gave a demonstration at the Royal Society of Medicine of some of these peculiarities.

When looking at people in a beam of ultra-violet through this glass the most striking things noticed are the fluorescence of the lens of the eye, the extreme whiteness of the sclerotic, the brilliance of natural teeth and the blackness of false ones, the whiteness of the finger-nails and the peculiar tow-like appearance of hair. The difference in the appearance of the complexion of individuals is very marked. While some show a marked fluorescence of the skin, in others it is completely lacking. The skins which do not fluoresce are apparently those which tan when exposed to the sun. But perhaps the most striking appearance is that of anyone who normally freckles; these show up with extraordinary clearness even in winter, when in ordinary light the individual appears to have lost the freckles completely. They seem to be potential centres of pigmentation, which only need exposure to sunlight for pigment to be deposited in the skin. Generally speaking, I think it may be said that the appearance of children and adults falls into three categories: frecklers, tanners, and those who do neither—people who simply redden in the sun and then peel. Their appearance in the ultra-violet beam is quite distinct from the other two classes.

It occurred to me that it might be interesting to see whether freckling is a characteristic shown by infants, and, by the courtesy of Dr. Boldero, I have had an opportunity recently, in the infant welfare clinic at the Middlesex Hospital, of seeing a number of infants under such conditions that they were illuminated only by these invisible rays. The first group of 14 infants ranged in age from a few months up to a year. Of the 14 attendant mothers seven were good examples of frecklers; but none of the infants showed freckling. On a second occasion, at a clinic of rather older children, a group of 31 children, ranging in age from about 2 to 5 years, were examined. Of the attendant mothers 11 freckled and three of their children showed freckles also; their ages were 4 years 1 month, 4 years 4 months, and 4 years 9 months. Of the other children of the freckling mothers, some showed that they would tan under sunlight exposure, others seemed to be devoid of this potential characteristic.

One other observation on these children seems worth recording, and that is the contrast between the appearance of their eyes and finger-nails and those of the adult. The whites of the eyes in children whom I have looked at in this way do not fluoresce in the brilliantly white manner of adults, and the appearance of the finger-nails, especially in very young infants, is not nearly so striking; in fact they can hardly be distinguished from the soft parts of the hand. In only one child, aged 2½ years, were the nails strongly fluorescent. This was a child upon whom Dr. Boldero asked me to make special observation as its nails were very brittle. It might be worth while to make more observations of this sort to see at what stage tissues of the body develop this power of fluorescence under ultra-violet radiation, and the local or generalised power of laying down pigment in the skin.

It is a common observation that summer tanning has practically faded by the approach of the winter months. It is also probably a common observation that the summer tanning of parts of the skin not ordinarily exposed to light does not fade so quickly as in the exposed parts. One returns from the sea with face and limbs well tanned. In a few months the face and hands have returned to their normal paleness, while the feet and arms from wrist to elbow are still quite brown. The question arises why this should be. May it not be possible that light, in contra-distinction to ultra-violet radiation, has a depigmentary action? There would seem to be a number of facts to support the suggestion.

I am, Sir, yours faithfully,

SIDNEY RUSS.

Barnato Joel Laboratories, Middlesex Hospital, Dec. 1st, 1930.

DENTAL CARIES AND DIET.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 29th (p. 1194) reference is made to an investigation by Mr. A. Deverall and Miss M. Reynolds into the influence of dietetic measures on the incidence and progress of caries in children's teeth. In this investigation 449 of 882 children, living on much the same diet, were given, one-half of them vitamins A and D, and the other half vitamins D; and "It was found, after four inspections representing one and a half years, that the percentage of teeth developing caries during this period" among the 449 children "was approximately half that in the control groups" who numbered 433. Manifestly the inference we are expected to draw from this investigation is that the administration of certain vitamins helps to check the onset of dental caries. But, Sir, there is no justification for this conclusion, for of the 433 controls (16 of whom, by the way, were given vitamin A) no less than 261 were given treacle—a potent source of dental caries.

This matter of dental caries is of such grave national importance that I feel impelled to add, with the utmost respect, that the Dental Board of the United Kingdom are not likely to further the object they have at heart by countenancing and publishing such unscientifically conceived methods of investigation as this. With the best intentions in the world, those who undertake such careless investigations do positive harm by suggesting that dental caries is due to defective resistance to caries of the tooth enamel (owing to defective composition), whereas it has been proved up to the hilt—and the truth needs to be driven well home—that it is due to the corrosive action of acid (from saccharide fermentation) on the enamel, and that this is no more capable of resisting corrosive acid than a marble slab; an acid with a strong affinity for calcium inevitably seizes upon that element when brought into close proximity to it.

Our duty to the public, then, is not to addle their heads with talk of vitamins (what do the primitive

unspoilt Australian Aborigines who subsist, as we all at one time did, by the hunt and on uncultivated vegetable food—what do they, with their magnificent teeth, know of vitamins?), but to point out that caries only originates in those areas where fermentable saccharide food lodges for protracted periods, such as between the teeth and in the pits of the grinding surfaces of the molars; that it practically never originates on a smooth enamel surface kept clean by the friction of the lips or tongue—e.g., on the lingual surface of the molars or on the labial surface of the incisors at a distance from the gum margin; and that, on account of the greater liability of some teeth to retain saccharide debris than others, some teeth are attacked 20 times more frequently with caries than others, although they are all nourished with the same blood, and all equally supplied with vitamins and other essential nutrients.

These are incontrovertible truths which plainly indicate our duty to the public; they show us how we can achieve immense good. Assuming the average number of carious teeth, past and present, in the jaws of our people to be five—a figure probably well within the mark—this gives a total of 230,000,000, a shocking record for a twentieth century civilised country, the more so when we reflect upon the attendant evils of dental caries, the unsightliness, the bad breath, the root abscesses, the pain, the blood poisoning, the false teeth, to say nothing of the visits to the dentist and the expense. The strange feature of this tragic story is our supineness in dealing with it, and the ready way in which we allow ourselves to be diverted by fanciful side-issues, when the pathology and means of prevention of dental caries have been known for several years. The means of prevention are set forth in Dr. Sim Wallace's handbook, "Teeth and Health," which is approved by the London County Council for use in their schools. The salient features insisted on are: that the dietary shall contain a sufficiency of cleansing foods, and of foods compelling adequate mastication, so that the jaws shall develop properly and the teeth be able to take up their proper positions in the gums; and that the order of the items of a meal shall be such as to minimise the tendency of saccharide food to linger in the retention areas of the teeth.

By a conscientious adoption of the measures set forth in this book it is possible to reduce the occurrence of dental caries almost to the vanishing-point.

I am, Sir, yours faithfully,

HARRY CAMPBELL.

Harley-street, W., Nov. 29th, 1930.

THE CLINICAL TRIAL OF MEDICINAL PRODUCTS.

To the Editor of THE LANCET.

SIR,—The Association of British Chemical Manufacturers has noted with particular interest the opinions in regard to clinical testing which are expressed in a letter by Dr. H. H. Dale appearing in your issue of Nov. 22nd. Attention is drawn particularly to the following paragraph:—

> "It (the case of ergot alkaloids) probably furnishes only a rather striking illustration of a general reluctance of medical men in this country to undertake clinical trials of anything new, under the conditions of scientific control needed to make the results worthy of record."

The satisfactory clinical trial of new medicinal products in this country is regarded as a matter of the greatest importance by this Association, which on various occasions since 1922 has called attention to the impediment to therapeutic progress in this country caused by the lack of published reports relating to new products. Their representations have so far not met with the success which was hoped for, and at present the development of new products for use in medicine is being seriously impeded by the inadequacy of the facilities for proper clinical trials. The result is that this country is being retarded in its efforts as compared with Germany, where a much more effective system is in operation.

The Association feels strongly on this subject, and as the time appears ripe for another effort, it proposes to take the matter up with the various organisations which are interested, in the hope that by coöperative action it may be possible to devise a scheme of clinical testing which will eliminate the handicaps under which medical science is at present labouring.

I am, Sir, yours faithfully,

J. DAVIDSON PRATT,
General Manager, Association of British Chemical Manufacturers.

166, Piccadilly, London, W., Nov. 28th, 1930.

PREVENTION OF SCARLET FEVER IN SCHOOLS

To the Editor of THE LANCET.

SIR,—Dr. Edge's letter in THE LANCET of last week on this subject makes me think that my experience at Uppingham may be of interest. Uppingham School is made up of 13 houses with central classrooms; each house has a population of approximately 50, including boys and domestic staff. Within the last three years scarlet fever has appeared three times (four cases, the disease was recognised early and confirmed by Schultz Charlton test), the patients were removed to sanatorium, the house was isolated and *every* inmate "Dick tested"; positives and doubtfuls were given a prophylactic dose of S.F. Serum (Wellcome). There were no more cases in any of the outbreaks. Two appearances of diphtheria were dealt with after the same manner with equally satisfactory results. Surely M.O.'s of schools have reason to be thankful for "Dick," "Schick," and "Schultz Charlton."

I am, Sir, yours faithfully,

WM. DUNN.

Woodfield House, Uppingham, Nov. 30th, 1930.

To the Editor of THE LANCET.

SIR,—May we be allowed to reply to Dr. D. Edge's courteous comments in your last issue upon our description of an Outbreak of Scarlet Fever at a Preparatory School in THE LANCET of Oct. 11th.

With regard to Dr. Edge's own experience, the fact that 15 cases of scarlet fever occurred in a day school of 250 girls in the autumn term (the usual period of greatest prevalence) and that these were followed by only two cases in the Lent term (the usual period of least prevalence) was not an unusual sequence of events; it might well have happened if no immunisation method had been used. It is significant that the Salford High School was presumably mainly a day school. Surgeon Captain Dudley[1] has shown the complete immunity from both scarlet fever and diphtheria of day boys at the Royal Naval School, Greenwich, when both diseases were prevalent amongst the boarders, an observation which as regards scarlet fever, our own experience at publi

[1] Med. Res. Council, Special Report Series No. 75. The Schick Test. Diphtheria and Scarlet Fever. A Study in Epidemiology. P. 46.

schools confirms. The age distribution of the girls (5 to 17) was probably in the main considerably higher than that of the boys in our investigation, none of whom was over 13; day pupils in the Salford school would probably contain a higher proportion of immunes. It appears also that, when Dr. Edge commenced his work, the outbreak was already nearing the end, whereas we were consulted when the epidemic was reaching its maximum, and, as examination of the cases will show, it was then too late for preventive inoculation to be effective promptly.

For the above reasons we consider that Dr. Edge's outbreak and ours are in no way comparable. Whilst we agree that to diminish the number of susceptibles and increase the number of immunes has a most important effect upon the herd immunity of the school, we feel that the success which crowned Dr. Edge's labours and upon which we congratulate him, was due in part to good fortune, and that similar success would not have been attained had we adopted the same method.

Further experience with immunisation against scarlet fever in schools or other institutions is very desirable. In estimating the results obtained by this method one must always bear in mind the special circumstances dealt with, in particular, the type of school or other institution (day attendance or residence), the stage of the outbreak when intervention was initiated, and the virulence of the infection.

We, are, Sir, yours faithfully,

J. A. GLOVER.
F. GRIFFITH.

TWINNING IN MONGOLISM.

To the Editor of THE LANCET.

SIR,—I should be much obliged if any correspondent who has statistics available will kindly tell me how many instances are known of twinning in mongolism, one of the children being a normal child and the other of mongol type. In the course of 33 years' work on mental deficiency I have only come across the occurrence twice, the second case having come to my personal attention this week.

I am, Sir, yours faithfully,

W. H. COUPLAND,
Medical Superintendent, Royal Albert Institution for the Feeble-minded of the Northern Counties.

Lancaster, Nov. 26th, 1930.

THE CHARTERHOUSE RHEUMATISM CLINIC.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Congdon's suggestion that the Charterhouse clinic team should confine its researches to one definite entity—namely, acute rheumatoid arthritis—I think that to do so would be a mistake. At the rheumatism clinic held at the public health offices, Brighton, and run on the same lines as the Charterhouse clinic, we find it very difficult to draw any definite line between the various types of rheumatism. In the present state of our knowledge, we doubt if such a definition serves any useful purpose, other than one of convenience, but rather that it confuses the issue still more. We doubt if any case of rheumatoid arthritis remains free for any length of time from either osteo-arthritis, fibrositis or neuritis. The work at the Brighton clinic is carried out on the supposition that the streptococcus and the staphylococcus play a large part in the causation of rheumatism, and that it is of considerable importance to realise that rheumatism is not a disease of particular type of tissue, but that it is essentially a disease of the whole body.

Dr. Congdon's use of a streptococcal vaccine for the treatment of rheumatoid arthritis is interesting, in that we find the majority of such cases are more sensitive to a vaccine prepared from Dr. Warren-Crowe's two types of staphylococci (Micrococcus D. & E.). This discrepancy is possibly explicable on the supposition that, if the resistance of the patient is such that he can become infected by the rheumatism-producing streptococcus, he is likely to become infected by the staphylococcus, both these types of organism being potential serophytes.

I am, Sir, yours faithfully,

F. E. GRAHAM-BONNALIE, M.B., B.Chir. Camb.

Hove, Sussex, Dec. 1st, 1930.

MINOR DIGESTIVE DISORDERS.

To the Editor of THE LANCET.

SIR,—Having read with interest Dr. Hunt's refreshing lecture in your issue of Nov. 8th, I am led to wonder what is to be gained by substituting the term "abdominal migraine" for bilious attacks unaccompanied by headache. For some years it has been the fashion to call these attacks "acidosis," which no doubt often accompanies them, but as both the headache and the acidosis are due to an unknown digestive cause, would it not be better to retain the old name "bilious attack" until our knowledge has advanced further, rather than by a new name to appear to lay claim to a knowledge that we do not really possess. Moreover, the adjective "bilious" is justified, for such attacks are frequently prevented or alleviated by the administration of calomel, or a similar drug leading to the passage of highly bile-stained motions.

I am, Sir, yours faithfully,

Paignton, Nov. 28th, 1930. ERNEST WARD.

VALUE OF RAMISECTION IN CASES OF SPASTIC WEAKNESS.

To the Editor of THE LANCET.

SIR,—In reply to Mr. Royle's letter in your last issue, may we have leave to state that the investigation reported in our note of July 19th was undertaken with the express purpose of meeting Mr. Royle's criticism that in cases adversely reported upon by others the operation had been incorrectly performed. The cases reported by us were selected by Mr. Royle, from a number which he examined, as likely to benefit from the operation. If, as he asserts, he chose the worst patients, it was presumably for some reason which we fail to appreciate.

As stated in our paper, the notes of our cases provided a mass of material so large that they were deemed inappropriate for publication in extenso. In reply to the points which Mr. Royle raises, we feel called upon to quote in more detail the notes of some of our patients.

Case 1.—Mr. Royle does not contest our observation that the patient was unimproved by the operation. He complains that no mention is made in our report of athetosis in this case. We have before us two neurological reports upon this patient, one by Dr. Fulton, who took part in the earlier stage of the investigations, the other by Dr. Symonds. Both observed tremor of a clonic type on attempted voluntary movement. Athetosis in our opinion was not present.

Case 2.—The selection from the notes of this case of an isolated observation recorded by one of the assistant medical officers on Feb. 25th, 1928, can be considered fortunate only as an example of Mr. Royle's singleness of vision. We print in full the pre-operative note on stance and walking, the notes of post-operative progress, and the final note on stance and walking :—

Before operation : (Note by Dr. Fulton.) "She stands unsupported some two or three seconds and then sinks backwards—sometimes with an attempt to restore balance by taking one or two steps back and usually without doing so. Supported gently by the hands (outstretched in front) she can walk slowly forwards. Turning is by a series of small turning steps, and usually ends in collapse backwards. The feet are cherry red and tend to be cold."

On June 22nd, 1927, Mr. Royle performed right lumbar ramisection ; 23rd, less spasm ; 24th, no increase in voluntary power ; July 1st, vaso-dilatation still persists ; right leg very stiff ; no definite improvement ; 12th, Mr Royle performed left lumbar ramisection and elongated both tendo Achillis ; Oct. 18th, position of feet satisfactory ; feet and hands cold and blue ; Dec. 31st, feet in good position ; walking not improved ; Jan. 25th, 1928, walks a little slowly ; Feb. 25th, feet satisfactory. *Can walk comfortably sometimes.* July 26th, discharged at request of parents ; no improvement since admission.

She was admitted into Guy's Hospital in May, 1929, under Dr. Symonds, who made the following note : "Cannot stand unsupported. Supported on both sides can walk dragging right foot along ground."

It will be seen that, taken in its context, the phrase (in italics) quoted by Mr. Royle conveys a very different impression from that given in his letter.

Case 3.—We have nothing to add to the opinion already expressed that the post-operative improvement was no more than might reasonably be attributed to spontaneous recovery from an acute hemiplegia.

Case 4.—Mr. Royle complained that immediate post-operative improvement noted by him is not mentioned in our report. The immediate post-operative record reads as follows : "Mr. Royle performed right lumbar ramisectomy on May 10th, 1927, and left lumbar ramisectomy on June 22nd, 1927. He saw the patient ten hours after operation and noted improvement. A note by the assistant medical officer states that there was temporary improvement." The purpose of our investigation was to discover our own views upon the results of the operation. Mr. Royle's opinions were already well known to us.

Case 5.—In this case Mr. Royle states : "The important point is that the patient was unable to walk before operation and walked unaided three weeks after ramisection." In the preceding sentence he has quoted Mr. Trethowan's observation that before the operation the patient was "able to walk with a little help." The first half, then, of Mr. Royle's statement is on his own showing inaccurate. As to the second half, our notes show that Mr. Royle performed left lumbar ramisection on May 10th, 1927. On June 21st, the note is "walks only with assistance." On June 23rd Mr. Royle performed right lumbar ramisection. The next note on walking is Feb. 7th, 1928. Mr. Trethowan noted "walks with assistance with high-stepping gait. Both tendo Achillis should be lengthened." On March 5th, 1928, this operation was performed. Subsequent notes read : "July 17th, 1928, not walking. August 2nd, gets along quite well with a chair ; gets heels to the ground. Sept. 11th, can walk a few steps by himself." From this time onward there is occasional note of improvement until on March 6th, 1929, the note is "walking with sticks." It appears from these notes that Mr. Royle's statement that the boy could walk unaided three weeks after ramisection is entirely unsupported by the facts, and that no improvement was observed until after the bilateral lengthening of the tendo Achillis performed by Mr. Trethowan nine months after Mr. Royle's final operation.

Case 6.—Mr. Royle states that this patient improved "even with regard to opening her hand." Our records, on the contrary, state under Jan. 21st, 1929, "the fingers cannot be moved voluntarily," and on March 17th, "the right arm is weak and spastic with fair power of movement in shoulder and elbow, very little in wrist, none in fingers." Our opinion, as already recorded, is that when examined on the latter date, the patient showed no improvement upon her pre-operative condition.

In reply to the concluding paragraphs of Mr. Royle's letter, we should like once more to emphasise that the purpose of our investigation was to record the results of ramisection as observed by ourselves, rather than by Mr. Royle or the patients, and we believe that the "honest seeker after truth" to whom he appeals may learn more from the report of six cases critically observed and recorded than from six hundred reviewed in the manner and spirit of Mr. Royle.

DIAGNOSIS OF PULMONARY TUBERCLE.

To the Editor of THE LANCET.

SIR,—I venture to make two comments on Dr. Burrell's instructive lecture. First, I think that he undervalues physical signs, especially as he makes a very brief reference to a most valuable sign, the existence of a difference in expansion of the two sides. If a difference in expansion is found on comparing the two sides, it is commonly the first sign discoverable ; and if the patient's history and symptoms suggest pulmonary tuberculosis, the indication for strict treatment is very definite. The different parts of the chest, back and front, as well as the costal margin and upper abdomen must be compared. In my experience it is seldom that there is no difference in a case of early pulmonary tuberculosis.

Next, Dr. Burrell speaks of "idiopathic" pleurisy being due to pulmonary tuberculosis. Much more frequently is it due to activity of glandular tuberculosis. It is true that the gland is originally infected from the lung, but the pulmonary focus may be quiet ; whereas the glandular infection may be active and produce an inflammatory reaction in the pleura.

I am, Sir, yours faithfully,

CHARLES MILLER.

Harrowby Court, W., Nov. 27th, 1930.

DEATH CERTIFICATION IN CORONERS' CASES

To the Editor of THE LANCET.

SIR,—My attention has been drawn to an article by Mr. J. P. Hedley in your issue of Sept. 20th last concluding with a statement that in the event of a practitioner feeling it his duty to report a death due to an abortion to the coroner "he should on no account sign the death certificate." As this instruction is contrary to the view which it has long been my duty to establish, will you kindly permit me to refer Mr. Hedley, and those of your readers who might otherwise have been disposed to take his advice to the following paragraphs on page iii. in the book o

Medical Certificates of Cause of Death in their respective possession :—

"Some doubts have existed as to the duty of practitioners to give certificates of cause of death in a case where an inquest may possibly take place. It is desired to point out that, as the law now stands, the duty placed upon a registered medical practitioner who was in attendance upon a deceased person in his or her last illness to give a medical certificate of the cause of death to the best of his knowledge and belief, appears to be unqualified, and unaffected by the fact that he or some other person has reported the case to the coroner or that an inquest may take place.

"The practice of refraining from giving a medical certificate of cause of death when the case is being reported to the coroner was to some extent strengthened by the fear that, if a medical certificate is given, the death may forthwith be registered and the body buried before an inquest can take place. Statement A on the back of the certificate has accordingly been included to obviate any such risk. If the practitioner when giving a certificate is also reporting the case to the coroner and accordingly initials Statement A on the back of the certificate, it will be the duty of the registrar to suspend the registration of the death until he learns from the coroner whether an inquest is or is not to be held."

I am, Sir, yours faithfully,

S. P. VIVIAN,
Registrar-General.

General Register Office, Somerset House, London, W.C.2.
Dec. 3rd, 1930.

PANEL PRACTICE

Relative Sickness of Men and Women.

Sir Alfred Watson, the Government Actuary in an address to the Institute of Actuaries, on Nov. 24th, reverted to the increase in sickness claims under the National Health Insurance Act since 1921, and touched on the difficult question of the sickness rate of women. If, he said, the popular generalisation that women are subject to more sickness than men means that out of an equal number of each sex the cases of incapacity in the course of a year will be more numerous among the women than among the men, such a generalisation is fallacious so far as unmarried women are concerned. Practically the whole of the excess in the women's rate is attributable to the difference in the duration of claims. Since the unmarried woman is apparently not subject to a greater risk of becoming incapacitated for work than a man of corresponding age, it is difficult, he added, to understand why, when sickness comes, the woman's average period of incapacity should be nearly half as long again as that of a man. He went on to suggest that the reason is not physical but economic. The majority of the insured men have wives and dependent families ; the majority of the unmarried insured women have no corresponding responsibilities. Apart from the immediate considerations which this difference of conditions creates, it is probable, on the whole, that the average man in industrial employment runs more risk than an insured women does of the loss of his job if he has to be long absent from work. The high rate of unemployment in many industries in which men only are employed, from which results the fact that the general rate of unemployment among men is normally about twice as high as it is among women, suggests that this may be a potent element in the case. Sir Alfred left it open whether it is to be inferred that many men return to work after sickness before they are fit for it, or whether a substantial proportion of women are apt to protract unduly their period of convalescence.

Uninsurables.

The National Medical Service Association, in a pamphlet commenting on the B.M.A. proposals for a general medical service, has pointed out one difficulty of any kind of contributory scheme. For it would exclude from its benefits a section of the population which stands in great need of medical attention. Four million persons, it is pointed out, including such types as hawkers, costermongers, cobblers, village blacksmiths, gypsies, tinkers, small shop-keepers and agricultural small-holders, whose economic position is often far inferior to that of many insured persons, have no part or lot in the present National Health Insurance, and can only be admitted by an amendment of the law bringing them in as "voluntary" contributors. Administrative difficulties in the way of securing the regular collection of contributions make illusory any hope of including the majority of these people. Contributions can be collected easily enough from the ordinary workman because the employer is obliged to deduct his share when paying wages, but such circumstances do not exist in the case, for example, of costermongers and other small entrepreneurs who have no employer and whose earnings depend entirely on their own exertions. A hawker may quite easily make £5 or £6 in one week, and only a few shillings for several succeeding weeks. He will neither attend at the Post Office each week to have his card stamped, nor commonly will he be in the position to pay a lump sum at the end of a quarter or half year. In addition, his contribution must be heavier because it must include not only his own, but the employers' share.

The N.M.S.A. is inclined to make use of the B.M.A. proposals, in spite of its deficiencies, as a step in the development of a national medical service. The importance of bringing an increasing number of the practitioners of the country into close contact with each other and with the existing public medical services cannot be over-estimated, and the scheme is regarded as shaping in this direction.

A GENEROUS GIFT TO DISTRICT NURSES.—An anonymous donor has given £100,000 as the nucleus of a fund to provide pensions for district nurses. It will be called "The 1930 Fund for Trained District Nurses." A committee to administer the fund has been formed, consisting of Sir Campbell Rhodes (Chairman), Sir William Foot Mitchell (Treasurer), Dame Maud McCarthy, Miss Musson, Miss Finch, Miss Darbyshire, Miss Cox-Davies, Miss Cockrell, Sir William Sheppard, and Mr. Arnold Herbert, K.C.

PAYMENT FOR HOSPITAL TREATMENT.—The governors of the Horton General Hospital, Banbury, have recently decided that patients with incomes not exceeding £350 a year shall pay a maintenance fee of 5s. per week, save in special circumstances when treatment will be free. Patients are admitted by a printed recommendation signed by a governor, or by a card issued by the Workpeople's Association. Accident and acute cases are admitted without formalities, and necessitous cases will be treated without payment.

ECCLES AND PATRICROFT HOSPITAL, LIMITED.—This institution has been registered as a company limited by guarantee, without share capital, with 600 members, each liable for £1 in the event of winding up. The following explanation of this step has been officially given : To recover, under the Health Insurance Act, expenses incurred in providing drugs, food, and bandages to panel patients, a hospital must be appointed panel chemists. But an unincorporated hospital is not qualified for such an appointment. When a hospital becomes a limited company it may open a dispensary and have a qualified chemist in charge, by which means it complies with the Pharmacy Acts. Then it receives the panel doctors' certificates and, having supplied the necessaries prescribed, its expenses in the matter become recoverable from health insurance funds.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

Buildings (Escape from Fire) Bill.

IN the House of Commons on Wednesday, Nov. 26th, Mr. GRAHAM WHITE asked leave to introduce a Bill to make further and better provision with respect to means of escape from buildings in case of fire. He said that the first clause provided that in the case of every new building which was more than two storeys in height or where the upper storey of any one floor was more than 22 feet from the ground there should be provided such means of escape for the persons employed therein, sleeping therein, or resorting thereto as might be considered reasonable in all the circumstances of the cases. The buildings to which these conditions should apply were tenement buildings, flats, maisonettes or buildings which were to be used as hotels, boarding houses, boarding schools, nursing homes, and the like. It was suggested that no such building should be occupied until a certificate had been given by the local authority that adequate means had been provided and that they existed in working order. The second clause provided in regard to existing buildings that if in the opinion of the local authority such building was not already provided with adequate means of escape in the case of fire they might call on the owner, by notice served in writing, to make such provision as might be considered reasonable in all the circumstances of the case, and the owner should then take the necessary steps to make provision. The third clause provided that similar conditions should apply in the case of buildings which were being converted for any of the uses described. The Bill also gave powers to local authorities to require owners to provide certain forms of mechanical sprinklers and mechanical apparatus for the extinction of fire. Anyone who was aggrieved by any provision of the Bill would have the right of appeal to a court of summary jurisdiction.

Leave was given to introduce the Bill, which was brought in and read a first time.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 26TH.

Detention of Dr. Dey.

Mr. MALONE asked the Secretary for Foreign Affairs whether he had any information concerning the detention of Dr. William Dey, a British-Canadian subject, on Oct. 21st, 1930, by the Polish authorities at Lemberg; what was the reason for the detention; and whether he was aware that Dr. Dey was refused permission to communicate with the British consul, Mr. Taylor.—Mr. HENDERSON replied: Yes, Sir. The circumstances of this case have been reported to me, and I have instructed H.M.'s Ambassador at Warsaw to make appropriate representations to the Polish Government.

Physical Fitness of Motor Drivers.

Mr. D. G. SOMERVILLE asked the Minister of Transport whether he was aware that during the past few weeks there had been an unusual demand for and distribution of motor driving licences available during 1931 as a result of the desire of many people to avoid the obligation of filling in the new licensing forms; and whether, with a view to reducing as far as possible the number of physically unfit drivers on the road before the speed limit was removed, he would take steps to obtain a declaration of physical fitness from all those who had obtained driving licences since Oct. 1st this year.—Mr. H. MORRISON replied: I am not aware that there has recently been any unusual demand for motor driver's licences. I have no power to call for a declaration of physical fitness from persons who have obtained driver's licences under the Motor Car Act, 1903.

Committee on Rural Housing.

Colonel BURTON asked the Minister of Agriculture whether he was now in a position to state the names of the committee he was appointing to inquire into the conditions of rural housing.—Dr. ADDISON replied: The members of the committee recently appointed by my right hon. friend the Minister of Health and myself, to inquire into the conditions of occupation of agricultural cottages, are as follows: Mr. W. R. Smith, Parliamentary Secretary to the Board of Trade (chairman); Mr. D. Black; Mr. G. Dallas, M.P.; Mr. H. H. George; Viscount Lymington, M.P.; Mr. J. C. McGrath; Miss E. Picton-Turbervill, M.P.

Hospital Sweepstakes.

Sir NICHOLAS GRATTAN-DOYLE asked the Prime Minister whether, seeing the success attending the Irish lottery on behalf of the Dublin hospitals, he would give facilities for the passing of legislation to legalise in this country the holding of sweepstakes or lotteries in aid of London hospitals or for kindred purposes.—Mr. MACDONALD (Prime Minister) replied: I can hold out no prospect of time being found for the discussion of this subject.

Sir N. GRATTAN-DOYLE: Is it not a fact that our laws concerning lotteries and sweepstakes are the laughing stock of the world?

Mr. MACDONALD: That question had better be addressed to the Home Office.

Mr. FOOT: Can the Prime Minister now give his attention to the request that has been made for the setting up of a select committee to deal with the whole matter of the existing gambling laws of the country?

Mr. MACDONALD: I am sorry I have not that in mind. If the hon. Member will put a question down I will give attention to the point.

THURSDAY, NOV. 27TH.

Mr. HANNON asked the Home Secretary if he proposed to introduce legislation to bring the law in this country into harmony with the law of the Irish Free State relating to hospital sweepstakes, so that British hospitals, which were in need of financial help, might benefit by the results.

Sir NICHOLAS GRATTAN-DOYLE asked the Home Secretary a similar question.—Mr. CLYNES replied: There has been no departure from the policy which has always been followed in the case of sweepstakes promoted outside this country. I am, however, fully aware that the circumstances connected with the recent sweepstake promoted in the Irish Free State call for serious and careful consideration from several points of view, but I am not at present in a position to make any statement as to the action which it may be desirable to take in the matter.

Maternity Cases in Prisons.

Viscountess ASTOR asked the Home Secretary how many babies had been born in prison in England and Wales during the 12 months ended July 31st, 1930; how many pregnant women prisoners had been transferred to outside hospitals or maternity homes for childbirth; whether any special diet was allowed to pregnant women in prison; and, if so, what was the nature of such diet.—Mr. CLYNES replied: During the 12 months ended July 31st last there were 14 births in prisons in England and Wales, and two in the Borstal Institution at Aylesbury. Special arrangements as regards diet are made in each case in accordance with the orders of the medical officer. No woman was transferred to a hospital or maternity home for childbirth and subsequently brought back to prison, but seven women were discharged from prison on that ground.

Industrial Diseases.

Mr. BROTHERS asked the Home Secretary if he would refer to the Departmental Committee appointed to inquire and report on proposals for extending or modifying the schedule of industrial diseases, under the Workmen's Compensation Act, the excess of respiratory illness amongst male cardroom workers in cotton mills.—Mr. CLYNES replied: Inquiries made by the Industrial Health Research Board at the request of the Home Office Departmental Committee on Dust in Card Rooms have established that there is a high incidence of sickness due to respiratory complaints amongst cardroom workers above a certain age, but I do not gather that there is any evidence to show that these complaints are distinguishable from the ordinary forms of respiratory disease. The Departmental Committee are, however, investigating the precise nature and cause of the sickness, and I will consider my hon. friend's suggestion when their report is received.

Inspection of Children's Homes.

Mr. SHEPHERD asked the Home Secretary the number of voluntary homes or institutions containing children and young persons not open to inspection; and the total population of such places.—Mr. CLYNES replied: I regret that I am unable to give the information asked for by my hon. friend. The Child Adoption Committee in its third and

final report, issued in 1926, drew attention to the fact that this information was not available, and recommended amendments of the Children Act which will be incorporated in the Children Bill now being prepared.

Mental Defectives.

Lieut.-Colonel FREMANTLE asked the Minister of Health whether the number of mentally deficient persons in this country had increased in recent years; if so, to what extent; and what was his present estimate of their number. —Mr. GREENWOOD replied: During the last five years the total number of mental defectives ascertained by local authorities under the Mental Deficiency Act has increased from 48,778 to 71,439—i.e., from 1·29 to 1·81 per 1000 of the total population of England and Wales. The ascertainment is not complete, and results vary in different areas. In these circumstances it is impossible to say whether the number of defectives is increasing in proportion to the total population, or to frame a conclusive estimate of the present number, but in certain areas the ascertainment by local authorities has reached 5 per 1000.

Voluntary Contributors to National Insurance.

Mr. THOMAS LEWIS asked the Minister of Health the number of persons who had become voluntary contributors under the National Health Insurance Act by virtue of the provisions of Section 21 of the Widows', Orphans' and Old Age Contributory Pensions Act, 1929.—Mr. GREENWOOD replied: The exact number is not available, but it appears from information supplied by the approved societies chiefly concerned that it is in the neighbourhood of 60,000.

Insured Persons and Continued Benefit.

Mr. THOMAS LEWIS asked the Minister of Health what action, if any, it was proposed to take relative to persons whose insurance under the National Health Insurance Acts would normally cease at the end of the present year.—Mr. GREENWOOD replied: I have summoned a meeting of the Approved Societies Consultative Council for Wednesday next to consider the matter, and after consultation with them I hope to be in a position to make a statement.

Inspection of Voluntary Maternity Homes.

Dr. BENTHAM asked the Minister of Health if all the voluntary maternity homes in receipt of a grant, paid previously by the Ministry of Health and now through local authorities, were still visited by the medical inspectors of the Ministry of Health.—Mr. GREENWOOD replied: The routine inspection of voluntary maternity homes is carried out by the responsible local authorities. The arrangements made for the training of midwives in maternity homes which are in receipt of grants from my department for that purpose are inspected periodically by a medical officer of my department, and I have retained the right to instruct my officers to visit any maternity home as occasion arises.

Red Cross Clinic for Rheumatism.

Mr. GRAHAM WHITE asked the Minister of Health if he had any information as to the progress of the work of the clinic for the treatment of rheumatism established by the British Red Cross Society; and if he was taking any steps to encourage the establishment of similar institutions in other localities.—Mr. GREENWOOD replied: I understand that this clinic is making satisfactory progress. I am always prepared to consider any schemes put forward by local authorities or otherwise for the treatment of rheumatism.

Statistics of Casuals and Lunatics.

Mr. SHEPHERD asked the Minister of Health why the monthly issue of statistics showing the numbers of casuals and lunatics had ceased.—Mr. GREENWOOD replied: My hon. friend is under some misapprehension. There has been no change in regard to the issue of these statistics. Figures for casuals have been issued in quarterly statements since 1919, and this practice is being continued. The number of lunatics on any day other than Jan. 1st has not been ascertained for many years. Patients in mental hospitals are no longer deemed to be in receipt of poor relief, and the numbers of such persons will not appear in future issues of the quarterly statement.

Deaths from Small-pox.

Mr. GROVES asked the Minister of Health whether any deaths occurred amongst the small-pox cases quoted in columns A, B, C, and D of the report of the chief medical officer; and, if so, what was the number, also the ages, in each class respectively.—Mr. GREENWOOD replied: 13 deaths occurred among the small-pox cases tabulated on p. 70 of the report of the chief medical officer of my department for the year 1929. These deaths, following the classification adopted in the tabular statement, were distributed as follows: Col. A (successfully vaccinated), 3 deaths of persons aged 14, 34, and 42 years respectively; Col. B (successfully revaccinated), no deaths; Col. C (unvaccinated), 9 deaths of persons aged 3 days, 3 weeks, 1 month, 8 months, 2, 9, 13, 37, and 63 years respectively; Col. D (vaccinal condition doubtful), 1 death of a person aged 74 years.

Royal Veterinary College.

Major CARVER asked the Minister of Agriculture what institutions for the promotion of veterinary science existed in the United Kingdom other than the Royal Veterinary College; whether his attention had been called to the danger that the College might have to close down for want of financial support; and whether, to avert this, he was able to offer more help than he had hitherto promised.—Dr. ADDISON replied: Besides the Royal Veterinary College, the following institutions in Great Britain provide veterinary education: Liverpool University; the Royal (Dick) Veterinary College, Edinburgh; and the Glasgow Veterinary College. In addition, the University Department of Animal Pathology at Cambridge, the Ministry of Agriculture's Veterinary Laboratory at Weybridge, and the Station of the Scottish Animal Diseases Research Association, near Edinburgh, exist for the purpose of research in animal diseases. I am fully acquainted with the financial position of the Royal Veterinary College. As the hon. and gallant Member is no doubt aware, the Government have offered to the College on certain conditions a grant of £150,000 towards a scheme of reconstruction costing £250,000, and are further prepared to contemplate an increase of the present maintenance grant when the reconstruction is completed. I sincerely trust that, with the help which the College may be able to obtain from other sources, these grants will be sufficient to avert the closing down of the College, an event which I should deeply deplore.

MONDAY, DEC. 1ST.

Insured Persons and Change of Panel Doctor.

Mr. RHYS DAVIES asked the Minister of Health whether he had now concluded his negotiations with doctors in panel practice and the approved societies for a variation of the period during which an insured person might change his panel doctor; and, if so, what arrangements had been arrived at.—Mr. GREENWOOD replied: On the question of principle, I have come to the conclusion that I ought to modify the relevant part of the Medical Benefit Regulations so as to require a longer period to elapse before effect is given to a notice by an insured person of his desire to transfer to another insurance doctor. Details of the procedure will be discussed with the representative bodies concerned as soon as possble.

Poison Gas Experiments.

Mr. FREEMAN asked the Secretary for War what were the positive tests of demonstrating the comparative effects of poison gases on human beings and living animals at present being pursued at the chemical warfare research departments. —Mr. T. SHAW replied: Examination of human beings who were gassed during the war and of animals subjected to experiment has shown essential similarities. From this it is deduced that protective and curative measures found effective in the case of animals will be applicable in the case of human beings. Tests, within the limits necessary to ensure that the volunteers come to no harm, are being carried out on the lines referred to in my answer of Nov. 25th. For example, contaminated materials, which have been treated for the purpose of cleansing the material from contamination, are brought into contact first with animals and then with human beings.

Leprosy in India.

Major GRAHAM POLE asked the Secretary for India, in regard to the measures being taken in India to avert the spread of leprosy, if he would give information showing in which provinces leprosy survey parties had been set up and village clinics opened with the support of the Government.—Mr. WEDGWOOD BENN replied: Leprosy surveys have been carried out in Bihar and Orissa, the Central Provinces, Madras, and in parts of Bengal, and leprosy clinics have been established by the local authorities in the areas covered by these surveys. In addition, numerous clinics have been opened in other parts of India by doctors trained in leprosy treatment during the last few years.

TUESDAY, DEC. 2ND.

Accidents to Boys in Mines.

Mr. FREEMAN asked the Secretary for Mines whether, in view of the fact that one-fourth of the boys under 16 years employed in mines were killed and injured in 1929, he would consider the suggestions put forward in the Northern Mines' Report for 1927 dealing with haulage accidents to boys under

16; whether he could offer any explanation of the high rate of fatal and non-fatal accidents to such boys from falls of ground in the South Wales coalfield; and whether he would consider adopting the example of Germany, mentioned in the 1927 Northern Mines' Report, in regard to the prohibition of boys under 16 from working underground, and the systematic training till that age on the surface, and over that age, till they were 18, below ground.—Mr. E. SHINWELL replied: The suggestions contained in the Report of H.M. Divisional Inspector of Mines for the Northern Division for 1927 relating to accidents to boys are engaging my serious attention, and while I cannot hold out any prospect of legislation under the present conditions of the mining industry, I shall do everything I can to bring to the notice of the industry the necessity for special measures to deal with the problem. With regard to the second part of the question, the high rate of accidents from falls of ground to boys in South Wales is due to the long-established custom in that district whereby boys start work at the coal face as colliers' helpers. Their initial employment on haulage work, as in other districts, is not practicable owing to the size of the horses and trams in use.

Physical Tests for Army Recruits.

Mr. LOUIS SMITH asked the Secretary for War what was the present shortage in the regular forces as a result of unsatisfactory recruiting returns; how many men had offered their services in each of the past 12 months; and how many had been rejected as physically unfit.—Mr. T. SHAW replied: The net shortage of warrant officers, non-commissioned officers, and men in the Regular Army, including the British Army in India, on Nov. 1st was approximately 8700. As regards the second and third parts of the question, records are not avaiable at the War Office to show the number of recruits rejected month by month on medical and physical grounds, but the total number of persons served with notice papers during the recruiting year ended Sept. 30th last, was 66,717, of whom 26,550 were finally approved; 35,425 were rejected on medical or physical grounds.

Mental Condition of Scottish Offenders.

Mr. STEPHEN asked the Secretary for Scotland the number of persons deprived of their liberty, through being incapable of pleading when charged with an offence, who had been certified sane for one year, two years, and three or more years, respectively.—Mr. ADAMSON replied: On Nov. 17th, 1930, there were ten inmates of the Criminal Lunatic Department who had been reported by the medical superintendent as being of sound mind for three years or more, one as being of sound mind for two years, and one as being of sound mind for one year. Of these 12 inmates, three were continuously detained in the institution during the respective periods in question, and nine had been at liberty under conditions during part of these periods.

Medical Examination of Pensioners.

Major CARVER asked the Minister of Pensions how many permanent awards had been made in the last year, and how many men were being re-boarded for medical examination; and whether he would consider the desirability of now making all awards permanent.—Mr. ROBERTS replied: During the 12 months ending September last, some 26,300 final awards were made. The number of officers and men medically re-examined at the instance of the Ministry has been greatly reduced, and at the present time is on an average not more than about 300 a week. I have full sympathy with the hon. and gallant Member's desire that medical examination should be reduced to the minimum possible. While there would be no power, nor would it be in the best interests of pensioners, to make final awards in all cases without regard to whether they were suitable or not, it is the policy of the department to give prolonged awards wherever justifiable.

MEDICAL NEWS

University of Oxford.

On Nov. 22nd the following degrees were conferred:—

D.M.—T. C. Hunt and O. R. Tisdall.
B.M.—J. N. O'Reilly.

University of Dublin.

At recent examinations in the School of Physic, Trinity College, the following candidates were successful:—

FINAL EXAMINATION FOR M.B., B.CH., AND B.A.O.

Medicine.—G. F. Ennis, D. J. O'Ryan, William Caldwell, T. H. Dockrell, C. H. Adderley, H. H. G. Dorman, Daniel Nolan, Charles Bowesman, C. M. Elliott, A. J. O'Connor, Kathleen A. Wilson, and Charles Ryan.

Surgery.—G. F. Ennis, D. J. O'Ryan, W. A. Robinson, E. S. Duthie, H. H. G. Dorman, N. A. Kinnear, William Caldwell, J. B. Scott, F. P. FitzGerald, D. G. Kennedy, and H. S. North.

Midwifery.—*Elizabeth K. Roberts, *Margaret D. Gregg, *Marjorie L. Campbell, *H. F. G. Irwin, I. G. L. Ford, J. C. M. Brambell, H. V. Tighe, W. A. Hill, J. G. Wilson, T. F. O'Donnell, E. S. Samuels, T. M. R. Ahern, M. G. Leane, T. J. O'Sullivan, F. C. Jackson, N. H. Leask, R. C. Sutton, Edward Morrison, J. A. Page, and D. H. S. Boyd.

* Passed on high marks.

University of London.

In the recent examination for the Diploma in Psychological Medicine Dr. J. W. M. Alexander was the successful candidate (with special knowledge of psychiatry).

The Paul Philip Reitlinger prize, of the value of £30, offered this year for the best essay embodying the result of research on a medical subject, has been awarded to Joseph Adler, a student of King's College and Charing Cross Hospital Medical School, for an essay on The Action of Histamine on Gastric Secretion after Partial Gastrectomy.

Fellowship of Medicine and Post-Graduate Medical Association.

On Monday, Dec. 8th, at 4.0 P.M., at 11 Chandos-street, London, W., Dr. Philip Figdor will lecture on Recent Advances in Osteo-Arthritis. Special free demonstrations will be given during the week as follows: at 2 P.M. on Monday, Dec. 8th., at the Children's Clinic, by Dr. Bernard Myers on Modern Methods of Infant Feeding; at 2 P.M. on Tuesday, the 9th, at the Royal Northern Hospital, by Mr. Kenneth Walker on Urological Cases; at 2 P.M. on Thursday, the 11th, at the Metropolitan Hospital, by Dr. P. Hamill in the out-patient department. The list of special courses for 1931 is now published, and copies may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

University of Aberdeen.

On Nov. 25th the Diploma in Public Health was conferred on Dr. Margaret F. Fraser.

Pharmaceutical Society of Great Britain.

At a meeting to be held at the Society's House, 17, Bloomsbury-square, London, W.C., at 8.30 P.M., on Tuesday, Dec. 9th, Prof. D. M. S. Watson, F.R.S., will lecture on Endocrine Organs.

North Staffordshire Orthopædic Hospital.

Lord Ednam last week laid the foundation-stone of extensions to the orthopædic hospital of the North Staffordshire Cripples Aid Society at Hartshall, Stoke-on-Trent. The new buildings, which will cost £20,000, are to be a memorial to Lady Ednam, the former president of the society, who was killed a few months ago in an aeroplane accident.

British College of Nurses.

Princess Arthur of Connaught, S.R.N., presided at this college, on Nov. 26th, at a lecture by Miss Isabel Macdonald on Nursing History. After referring to the traces of nursing history in the ancient civilisations of India, Persia, Chaldea, Egypt, Greece, and Rome, Miss Macdonald showed a series of lantern slides illustrating the work of the Church and of various saints who had made it a part of their mission to care for the sick. These included the Empress Helena, who, with her son Constantine (A.D. 272–337), built shelters for strangers and pilgrims; Matilda, consort of King Stephen, who founded the hospital of St. Catherine by the Tower, Queen Eleanor, first consort of Edward I., and Queen Philippa of Hainault, consort of Edward III., who were also connected with this hospital, of which the Queen's Institute of District Nursing was the modern exposition. Their record inspired Miss Macdonald to search the annals of Scottish history to find a royal Scottish nurse who could be placed with them. She found her in St. Margaret, consort of Malcolm Canmore, who was renowned for her beneficent work for the sick and poor. Many further pictures brought the history of nursing down through the centuries to the time of Elizabeth Fry, Friederike and Caroline Fliedner, and Florence Nightingale, and the movement inspired and guided by her towards higher education and nursing knowledge. This was followed, said Miss Macdonald, by the movement for professional organisation, through State Registration, and the International Council of Nurses, the successful life-work of Mrs. Bedford Fenwick, President of the British College of Nurses.

Sweepstakes for Hospitals.

The board of management of Manchester Royal Infirmary has decided to call a conference of 50 governors, representing the 25 hospitals in Manchester and Salford, to discuss whether sweepstakes are a desirable method of raising funds.

A Hospital in Danger.

The Victoria Infirmary, Northwich, Cheshire, is said to be in some danger of subsidence in consequence of brine pumping. Portions of the park in which it stands are crumbling, and a fissure has appeared close to the hospital. Meanwhile there is heavy pressure upon the accommodation, and many patients have to be sent to Manchester and Liverpool institutions. The governors are considering the possibility of providing a new building outside the brine-pumping zone.

The Hospital Saving Association.

The annual report of this Association shows that during the year ending July 31st 1275 new groups were formed, and that the number of contributors increased by 158,431. There are now 7986 groups and 810,444 contributors. The year's contributions amounted to £438,354, as compared with £320,714 in the previous year. During the year 238,929 contributors and dependents, of whom 44,340 were in-patients, were treated at voluntary hospitals on the list of the Association. The number of days of in-patient maintenance was 911,873, giving an average length per case of 20·58 days. The total payment for hospital services for the year is £325,781.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Dec. 8th.—5 P.M., UNITED SERVICES. Paper: Major-General H. Ensor: The Medical Services of a Division on Active Service.

TUESDAY.—5 P.M., THERAPEUTICS. Discussion on The New Mercurial Diuretics and Their Uses in Medicine, with special reference to Novasurol and Salyrgan. Opener: Dr. Evan Bedford. Other speakers will also take part. MEDICINE. Members of this Section are specially invited to attend and take part in the discussion. 8.30 P.M., PSYCHIATRY. Paper: Dr. N. H. M. Burke: Stigmata of Degeneration in Relation to Mental Deficiency.

THURSDAY.—8.30 P.M., NEUROLOGY. (Cases at 7.45 P.M.) Clinical Meeting at the National Hospital, Queen-square, London, W.C.1.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 4.30 P.M.) Cases: Mr. Cecil P. G. Wakeley: 1. Calcified Endothelioma of the Brain. 2. Acromegaly, Treated by the Introduction of Radon Seeds into the Pituitary Body. 3. Vascular Tumour of the Brain after Operation (shown at the October meeting). Sir James Dundas-Grant: 4. Headache Apparently Due to Enlargement of Middle Turbinated Body, Relieved by Intranasal Operation. Dr. Geoffrey Evans: 5. Bronzed Diabetes. Dr. B. Barling: 6. Arterial Obstruction in the Lower Limbs Treated with Angioxyl, &c. Dr. A. P. Cawadias and Dr. F. Parkes Weber: 7. Syndrome of Obliterating Arteritis of the Lower Limbs Treated with Angioxyl and Various Physical Agents. Dr. F. Parkes Weber: 8. Hæmochromatosis with Diabetes Mellitus, Hepatic Cirrhosis and Ascites. Dr. E. Stolkind: 9. Parkinsonian Syndrome showing Peculiarities of Speech Records. 10. Parkinsonian Syndrome (Post-Encephalitic Paralysis Agitans) with Affection of the Speech as First Manifestation. Dr. L. Hartston: 11. Still's Disease. Dr. Donald Hunter: 12. Hyperparathyroidism; Generalised Osteitis Fibrosa with Multiple Osteoclastomata. Dr. Philip Ellman: 13. Pulmonary Asbestosis. 14. Pulmonary Tuberculosis with Absence of Left Pectoral Muscle and Tuberculous Ulcer of Tongue. Other cases will be shown. 5 P.M., OPHTHALMOLOGY. Clinical Meeting at the Central London Ophthalmic Hospital, Judd-street, W.C. Tea at 4.30 P.M. Cases: Mr. J. H. Doggart: 1. Complicated Cataract of Obscure Origin. 2. Old Mustard Gas Burns. Other cases will be shown.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Dec. 8th.—8.30 P.M., Discussion on The Pathological Conditions of the Eye Due to Inflammatory Changes in Other Parts of the Body, to be introduced by Mr. A. F. MacCallan, followed by Mr. Ernest Clarke.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Dec. 11th.—7.45 P.M., Demonstration by Sir Aldo Castellani. 8.15 P.M., Major G. Shanks, I.M.S: A Demonstration (with lantern slides) on the Pathology of Epidemic Dropsy in Bengal; and Sir Aldo Castellani: A Paper on Minor Tropical Diseases (illustrated by lantern slides).

HARVEIAN SOCIETY.

THURSDAY, Dec. 11th.—8.30 P.M. (at Town Hall, Paddington Green, Harrow-road, W.), Dr. H. W. Barber: Skin Lesions of Interest to the General Practitioner.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, Dec. 12th.—8.45 P.M. (at the Miller General Hospital, Greenwich-road, S.E.), Mr. A. J. Walton: The Neuro-muscular Obstructions of the Intestinal Tract (Purvis Oration).

THE EUGENICS SOCIETY.

WEDNESDAY, Dec. 10th.—8.30 P.M. (at the Rooms of the Linnean Society, Burlington House, W.), Heredity in Education. Speakers: Dr. Maitland Radford and others.

BIOCHEMICAL SOCIETY.

FRIDAY, Dec. 12th.—5 P.M. (in the Department of Physiology, London Hospital), Communications and Demonstrations.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn-fields, W.C.

MONDAY, Dec. 8th, and following WEDNESDAY.—4 P.M., Mr. F. W. Twort: Diseases of Bacteria. (Free lectures.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Dec. 8th to SATURDAY, Dec. 13th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon. at 4 P.M., a free lecture by Dr. Philip Figdor on Recent Advances in Osteo-arthritis.—CHILDREN'S CLINIC, Cosway-street, Edgware-road. Mon. at 2 P.M., special demonstration on Modern Methods of Infant Feeding by Dr. Bernard Myers. No fee.—ROYAL NORTHERN HOSPITAL, Holloway-road. Tues. at 2 P.M., special free demonstration of Urological Cases by Mr. Kenneth Walker.—METROPOLITAN HOSPITAL, Kingsland-road. Thurs., at 2 P.M., special free demonstration in Out-patient Department by Dr. P. Hamill.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street. Special course in Neurology at 5 P.M. daily.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars. Afternoon course in Dermatology.—INFANTS HOSPITAL, Vincent-square, Special afternoon course.—Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 8th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.

THURSDAY, Dec. 11th.—9 P.M., Dr. J. A. Drake: Some Common Skin Diseases, illustrated with Epidiascope.

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Dec. 8th.—4.15 P.M., Dr. Charles Singer: Eighteenth Centenary of the Birth of Galen.

CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C.

THURSDAY, Dec. 11th.—5 P.M., Mr. A. L. Walker: Management of Toxæmias.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 9th.—5 P.M., Dr. A. C. Roxburgh: Eruptions Due to Physical Agents.

THURSDAY.—5 P.M., Dr. W. N. Goldsmith: Pigmentation of the Skin.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, Dec. 10th.—4 P.M., Dr. C. E. Lakin: Demonstration of Medical Cases.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Dec. 10th.—4.30 P.M., Dr. Jenner Hoskin: Value of Complete Cardio-analysis in Genito-urinary Operations.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Dec. 12th.—4 P.M., Mr. Lowndes Yates: The Indications for Removal of Tonsils.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Dec. 9th.—3.15 P.M., Mr. G. G. Penman: Fundus Changes in Diseases which Do Not Directly Affect the Eye.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Dec. 10th.—4 P.M., Sir Hubert Bond: Prevention of Mental Illness.

THURSDAY.—4 P.M., Dr. Marie Stopes: Positive and Negative Control of Conception in its Various Technical Aspects.

INSTITUTE OF HYGIENE, 28, Portland-place, W.

WEDNESDAY, Dec. 10th.—3.30 P.M., Mr. P. V. Cole: Some Preventive Aspects of Cancer.

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY, Aldwych House, Aldwych, London, W.C.

THURSDAY, Dec. 11th.—6 P.M. (in Room 9 at the London School of Economics, Houghton-street, Aldwych, W.C.), Mr. W. J. Pinard: Tests of Character; Mr. C. B. Fox: Industrial Psychology Applied to the Blind.

ANCOATS HOSPITAL, Ancoats, Manchester.

THURSDAY, Dec. 11th.—11 A.M., Mr. E. E. Hughes: Clinical Demonstration; 4.15 P.M., Dr. A. Renshaw: The Use of Vaccines.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Dec. 9th.—4.15 P.M., Mr. A. H. Burgess: The Early Diagnosis of Breast Carcinoma.

FRIDAY.—4.15 P.M., Mr. Gordon Whitehead: Treatment of the Common Complications of Gonorrhœa.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.

FRIDAY, Dec. 12th.—3.30 P.M. (at the Royal Infirmary), Mr. Connell: Syphilis as it Affects Bones and Joints.

Appointments

Middlesex Hospital: BONNEY, V., M.D. Lond., F.R.C.S. Eng., Obstetric and Gynæcological Surgeon; RIVETT, L. C., M.Chir. Camb., F.R.C.S. Eng.; and ROQUES, F. W., M.D. Camb., F.R.C.S. Eng., Asst. Obstetric and Gynæcological Surgeons.

Certifying Surgeons under the Factory and Workshop Acts: FRASER, D. (Dursley, Gloucester); PIGOTT, E., M.B., Ch.B. Manch. (Manchester West Central); and SULLIVAN, J., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S.G. (Ebbw Vale).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Hon. Jun. Ophth. Surgeon.

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

All Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road. H.S. At rate of £150.

Birkenhead General Hospital.—Sen. H.S. £150.

Bridge of Weir Sanatorium, Renfrewshire.—Res. Asst. M.O. At rate of £200.

Burnley, Victoria Hospital.—Two H.S.'s. Each at rate of £150.

Bury Infirmary, Lancashire.—3rd H.S. At rate of £150.

Cheshire Joint Sanatorium, Market Drayton, Salop.—H.P. £250.

Carlisle, Cumberland, and Westmorland Mental Hospital, Garlands.—Jun. Asst. M.O. £350.

Chester Royal Infirmary.—H.S. £150.

Connaught Hospital, Orford-road, Walthamstow, E.—Sen. Res. H.S. At rate of £150.

Derbyshire Royal Infirmary.—Non.-Res. Radiologist. £100.

Dreadnought Hosp. Greenwich.—H.P. and H.S. At rate of £110.

Dunedin, New Zealand, Otago University.—Prof. of Midwifery and Gynæcology. £2000.

Dunfermline, West Fife Infectious Diseases Joint Hospital.—Asst. M.O. £400.

East London Hospital for Children, &c., Shadwell, E.—H.S. At rate of £125.

Essex County Council.—Asst. County M.O.H. £500–£600.

Evelina Hospital for Children, Southwark, S.E.—Hon. Dental Surg.

Exeter, Royal Devon and Exeter Hospital, Pathological Department.—Pathologist. £500.

Glasgow Corporation, P.H. Dept.—Deputy M.O. for Mental Services. £1000.

Grocers' Company, Grocers' Hall, E.C.—Research Scholarships. £300.

Hampshire County Council.—Asst. County M.O. £600.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, St. John's Wood, N.W.—Gynæcological Surg.

Hull Royal Infirmary.—H.S. to Ophthalmic, &c. Depts. At rate of £150.

Hull Royal Infirmary, Sutton Branch.—H.P. At rate of £160.

Ilford, King George Hospital.—Hon. Physician.

Indian Medical Service.—Commissions.

Jersey General Hospital and Poor-law Infirmary.—Res. M.O. £200.

Kidderminster and District General Hospital.—H.S. £150.

Liverpool University.—Jun. Lecturer in Dept. of Pathology, £300.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150.

London Hospital, E.—Surg. 1st Asst. and Reg. £300.

Manchester, Ancoats Hospital.—H.S. for General Surgery, &c. At rate of £100. Med. and Surg. Registrars. Each £100. Also Orthopædic Reg. (part-time). £25.

Metropolitan Hospital, Kingsland-road, E.—Asst. M.O. to X-ray Dept.

Miller General Hospital, Greenwich-road, S.E.—H.P. and H.S. At rate of £125. Also Out-patient Officer. At rate of £150.

Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H.S. At rate of £100.

New Zealand, Hawkes Bay Hospital, Napier.—Pathologist. £750.

Nottingham City Infirmary, Hucknall-road.—Two M.O.'s. Each £350.

Oswestry, Shropshire Orthopædic Hospital.—Asst. Orthopædic Surgeon. £450.

Perth Royal Infirmary.—Res. Jun. H.S., and H.P. Each £100.

Pontefract General Infirmary.—H.S. £150.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Hon. Anæsthetists. Hon. Dental Surgeon. Hon. Psychiatrist. Also Res. Anæsthetist, and Asst. Res. M.O. At rate of £100 and £80 respectively.

Queen's Hospital for Children, Hackney-road, E.—H.S. At rate of £100.

Radium Institute, Riding House-street, W.—H.S. At rate of £150.

Reading, Royal Berkshire Hospital.—H.P., and Two H.S.'s. Each at rate of £150.

Royal Dental Hospital of London, 32, Leicester-square, W.C.—Hon. Radiologist and Lecturer in Radiology.

Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.

Royal Waterloo Hospital for Children and Women.—Res. H.S. At rate of £100.

Ruthin Castle, North Wales.—Jun. Res. Physician.—£200.

St. Mary's Hospital, W.—Surgical Registrar. £200.

St. Peter's Hospital for Stone, &c., Covent Garden, W.C.—Clin. Assts.

St. Thomas's Hospital.—Chief Asst. in Physico-therapy Dept. £250.

Salford Royal Hospital.—Res. Surg. O. At rate of £200. Also H.P., Two H.S.'s, and Cas. H.S. Each at rate of £125.

Salisbury, General Infirmary.—H.S. £150.

Sheffield Royal Hospital.—Ophth. H.S. Also Res. Anæsthetist. Each at rate of £80.

Sheffield Royal Infirmary.—Ophth. H.S. £80–£100. Clin. Asst. to Ear, Nose, and Throat Dept. £300. H.P., H.S., Asst. Aural and Ophth. H.S. Also Asst. Cas. O. All at rate of £80.

South London Hospital for Women, South Side, Clapham Common, S.W.—Three H.S.'s. Each at rate of £100.

South Shields, Harton Hospital.—Two H.S.'s. Each £120. Also X Ray and U.V.R. Operator. £250.

Staffordshire County Council.—Asst. Bact. and Path. £600.

Talgarth, Breconshire, South Wales Sanatorium.—Asst. Res. M.O. £250.

Tilbury Hospital, Essex.—H.S. At rate of £150.

Watford, Herts, Peace Memorial Hospital.—Res. Surg. O. At rate of £150.

West African Medical Service.—Medical Officers.

West London Hospital, Hammersmith-road, W.—Non-Res. Cas. O. £250. Also H.P., H.S., and Aural and Ophth. H.S. Each at rate of £100.

Weston-Super-Mare General Hospital.—Res. H.S. At rate of £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Surg. Reg.

Wigan, Royal Infirmary.—H.S. At rate of £150.

Woking and District Victoria Hospital.—Res. M.O. At rate of £100.

Woolwich and District War Memorial Hospital, Shooters Hill S.E.—H.P. At rate of £100. Also Part-time Pathologist £300.

Worcester General Infirmary.—Jun. Res. M.O. £120.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Chipping Campden (Gloucestershire); Llandovery (Carmarthenshire); and at Stromness (Orkney).

Births, Marriages, and Deaths

BIRTHS.

DALTON.—On Nov. 11th, at Fonnereau-road, Ipswich, the wife of Dr. C. H. C. Dalton, of a son.

DAVENPORT.—On Nov. 24th, at Adelaide-road, N.W., the wife of Robert Davenport, F.R.C.S., of a daughter.

HARRIS.—On Nov. 17th, at a nursing home, Muswell Hill, the wife of Dr. J. R. Harris, of a son.

ILLINGWORTH.—On Nov. 26th, at Palmerston-place, Edinburgh, the wife of C. F. W. Illingworth, F.R.C.S., of a son.

INKSTER.—On Nov. 15th, at Middlesbrough, the wife of John Inkster, M.D. Aberd., M.R.C.P. Lond., of a daughter.

NELSON.—On Nov. 24th, at Harley-road, N.W., the wife of H. P. Nelson, F.R.C.S., of a daughter.

PATERSON.—On Nov. 20th, at Chatfield, Parkstone, the wife of Dr A. R. Paterson, of a son.

SMITH.—On Nov. 26th, the wife of Dr. Wilson Smith, Sunbury gardens, Mill Hill, N.W., of a daughter.

STOCKER.—On Nov. 21st, at Lancaster, the wife of Major C. J. Stocker, I.M.S., of a son.

MARRIAGES.

MAITLAND—WEMYSS.—On Nov. 24th, at St James's Church, Cupar, Fife, David Randolph Maitland, M.B., Ch.B., to Barbara Mary Carnegie, only daughter of Mr. E. H. Wemyss, of Kirkton, Fife, and Mrs. Wemyss, at Myres Castle, Auchtermuchty, Fife.

DEATHS.

GALE.—On Nov. 23rd, at Stuston Lodge, Diss, Annabella Murdoch Gale, M.D., B.Sc.

HINGSTON.—On Nov. 28th, at a nursing home, suddenly, Richard Hingston, M.R.C.S., L.R.C.P., late of Liskeard, Cornwall, aged 71.

HORWOOD.—On Nov. 16th, at Smallburgh Rectory, Norwich, Oswald Ryle Horwood, Clerk in Holy Orders, Physician and Surgeon.

MAYSTON.—On Dec. 1st, at Upper Clapton-road, John Harry Mayston, M.R.C.S., L.R.C.P., in his 46th year.

MILLER.—On Nov. 27th, at Cheviot, Neasden, Walter Frederic Miller, M.B., B.S., late of Wainfleet, aged 59.

NICHOL.—On Nov. 28th, suddenly, at Ethelbert-crescent, Margate, Frank Edward Nichol, M.B., B.Ch., J.P., aged 69 years.

SHAW.—On Nov. 25th, Dr. Arthur Hemans Shaw, of Cranbrook, Kent, aged 70.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

PITFALLS IN THE NEW MOTORING LAW.

THE passing of the Road Traffic Bill, 1930, has confronted every motorist in the country with a radical change in the motoring law. Great efforts have been made by the press, assisted by competent lawyers, to prepare them for their new duties, but there must be many motorists still who would not do very well in an examination on the subject. One of the latest of the expositions was given on Friday last to the Solicitors' Managing Clerks' Association by Mr. C. Doughty, K.C., who demonstrated a few traps which possibly have escaped the notice of other advisers. One of the most serious of these for the ordinary owner-driver is contained in the provision which lays down that any person who gives false information for the purpose of obtaining a licence or certificate is liable to a fine of £50 or four months' imprisonment. "Unfortunately,"—to quote the *Mikado*—"there is not a word about a mistake, or not knowing, or having no notion. There should be, of course, but there isn't." The section does not contain the word "wilfully," and an offender will be liable to the penalty for an innocent mistake made by himself or—what is more likely—by an agent. There will be plenty of scope for argument over the question of what information is material and, as Mr. Doughty said, what time must elapse before a former accident may be discreetly and safely forgotten.

The section governing the information that must be contained in the certificate of insurance is not so Draconic, and the responsibility lies chiefly with the company. The motorist should remember that he must carry this document with him whenever he takes the car out, and that he is bound to produce it, not only on the demand of a policeman, but whenever he is requested to by any person who may reasonably make the request. The provision is apparently designed to enable interested parties to ascertain whether the car is being driven under the conditions of the policy, or by a person entitled to drive in accordance with it. The certificate, according to the Act, must contain particulars of the limitations on the use of the car, such as those prohibiting its use for trade purposes or speed testing. Mr. Doughty said that it was probably unnecessary to name every person who was covered against third party risks by the policy, and that the law would be satisfied if the class of person were named; for example, relatives, friends, or servants.

The Act recognises three forms of unlawful driving: reckless or dangerous driving, for which the penalty is £50 or four months for the first offence; a new offence called careless driving; and a breach of the speed limit, which is not to be imposed on private cars. A driver charged with careless driving may be convicted of dangerous driving, even though the substantive evidence is that he was going too fast, if other circumstances are proved that aggravate the offence—such as the presence of cross-roads or the possibility (not the fact) of other traffic being in the vicinity. Dangerous driving being an indictable offence, it is therefore open to a person accused of one of the minor offences to elect to be tried by a jury. In police-courts it is probable, said Mr. Doughty, that a separate summons will be issued for each charge; the driver will then presumably plead guilty to the lesser offence in the hope of escaping the consequences of the greater.

Mr. Doughty pointed out a quaint possibility arising from the expression "under the influence of drink or drugs." Since the conjunction "or" presumably creates two mutually exclusive offences, it will be a good defence when charged with drunkenness to plead the influence of drugs. Both Mr. Doughty and Mr. Justice Swift, who took the chair, anticipated a considerable increase in motor-car litigation and prosecution. Motorists will be well-advised to proceed with very great caution for a considerable time after the new legislation comes into force.

CECIL HOUSES FOR HOMELESS WOMEN.

ON Nov. 19th, Mr. Ramsay MacDonald opened the Fourth Cecil House at 179, Harrow-road, London, W. This new public lodging-house accommodates 60 women and 17 babies, with a special sitting-room and dormitory for the mothers and children. Since the first house was opened in 1927 over 148,015 beds and 17,956 cots have been occupied. Nevertheless, it is stated that the supply by no means equals the demand and that each week some 40 to 80 women have to be turned away through lack of room. Once the initial expenditure—purchase of freehold, reconstruction, equipment—is defrayed from moneys subscribed by the public each house is entirely self-supporting. The aim is to establish another house as soon as possible in order to meet the needs of winter. Particulars may be had from the honorary organising secretary, Mrs. Cecil Chesterton, at the offices at 11, Golden-square, W.1.

CHOCOLATES.

WE have received from Messrs. Cadbury Bros., Ltd., an assortment of their new productions, timed no doubt to coincide with the Christmas season. The collection of sweetmeats entitled "Golden East Assortment" is likely to prove a popular present. Among other delicacies, new or put up in a new way, may be mentioned the Brazil-nut milk chocolates, Princess Elizabeth chocolates, and the Carnival chocolates, all of which are packed in appropriate fashion to form cadeaux. This packing of what the manufacturers call "the silent theatre box," has been devised to meet the criticisms of playgoers who complain of the rustling of receptacles for sweetmeats. The chocolates are packed between non-rustling paper, and a pad enclosed in cellophane is fixed inside the lid. The lid itself is covered in cellophane and need not be broken when opening, as a narrow seal can be torn noiselessly to free a hinged lid.

A selection of the firm's well-known wafer biscuits has also reached the office, with sample tins of Bourneville cocoa and cup chocolate.

AN ECCENTRIC.[1]

THE biography of Ronald Firbank has been sent to THE LANCET for review, presumably because the author, or some of those who supplied personal reminiscences in elucidation of the subject, believed that Firbank's life was of medical interest. A more charitable view can be taken, and we may hold that we have here an example of eccentricity of conduct; and where this may begin is often hard to say, while where it may reach a stage to which the term is no longer applicable, is still harder to define. It is made very clear in the book that Firbank was his own enemy and a very uncomfortable friend, while the comments on his neglected writings will arouse curiosity.

APPENDICITIS AMONG THE CHINESE.

THE popular opinion that Chinese are little susceptible to appendicitis—less susceptible than Europeans or Americans—has been again submitted to examination, this time by Dr. J. Heine, pathologist during 1928–30 to the Tung-Chi University and the Paulun Hospital at Shanghai. His results appear as a supplement to the *Archiv für Schiffs- und Tropen-Hygiene* of Leipzig. He concludes that appendicitis is no rare disease among Chinese, but that they are less

[1] Ronald Firbank, a memoir by Ifan Kyrle Fletcher, with personal reminiscences by Lord Berners, Augustus John, V. B. Holland, and Osbert Sitwell, with portraits by Alvara Guevara, Augustus John, R. A., Wyndham Lewis, and Charles Shannon, R.A. London: Duckworth, 1930.

apt than others to consult European doctors about it and to undergo operation. This conclusion accords with the opinion of Dr. Elsa Uhlenhuth quoted in THE LANCET last year (1929, i., 618). Dr. Heine had three sources of information. Among 856 specimens sent him after operations on Chinese, there were 37 appendices, of which 36 were inflamed (4·2 per cent.); while among 185 specimens sent him after operations on Caucasians there were 40 appendices, of which 32 (17 per cent.) were inflamed. He made 32 post-mortem examinations on Chinese, aged from 2 to 55, and examined all the appendices, naked eye and microscopically, at least three sections of each being taken. Of these 28 (82 per cent.) were abnormal, but 6 were tuberculous and 3 others were associated with intestinal disease, leaving 19 examples of "idiopathic" appendicitis (56 per cent.) of which 5 had recovered and 14 were still in the stage of convalescence. In his well-documented paper Dr. Heine gives facts and figures which lead him to think that neither climate, race, food, nor intestinal parasites are involved in the ætiology of the disease.

NEW PREPARATIONS.

ALMATA (Messrs. Keen, Robinson and Co.).—The following is the analysis of this preparation which has already been favourably reported upon: egg yolk, supplying protein, fat, and vitamins A, B, D, E; butter, supplying fat and vitamins A and D; maltodextrins, supplying carbohydrates; and decitrated fruit juice, supplying vitamin C. In accordance with this analysis the claim is made that the food approximates to breast milk more closely than any other infant food, while the fat and calcium absorption are high. The mineral content is similar to that of breast milk, and the laxative action is due to the maltodextrins.

(1) CAMPHRO-SALYL AND BENZYL SALICYLATE, (2) FERRUGINOUS AMPOULES.—We have received from the English agents, Messrs. Wilcox, Jozeau and Co., 15, Great Andrew-street, London, samples of these new remedies emanating from the Laboratoires Fraisse, 8 Rue Jasmin, Paris. (1) Camphro-salyl is a compound of benzyl salicylate and camphor. Benzyl salicylate is an exact chemical substance of the nature of a phenol ester and is obtained by the action of salicylic acid on benzyl alcohol. This crystalline powder was found to be analgesic but when combined with camphor its effect was much increased. The compound is put up in ampoules and is sold in boxes of six, each ampoule containing benzyl salicylate 0·50 g., camphor 0·10 g., and olive oil 5 c.cm. It is recommended for its effectiveness in acute or chronic neuritis.

(2) Ferruginous ampoules is a preparation of the cacodylates of iron and strychnine with sodium glycerophosphate, and has been used with success in anæmia following accident or surgical operation, and that accompanying the menopause or uterine fibroids. In this preparation the chemists appear to have triumphed over the difficulty that few salts of iron are assimilable subcutaneously and that treatment by injection is generally very painful.

THE MEDICAL DIRECTORY FOR 1931.

THE eighty-seventh annual issue of the Medical Directory, which reached us in November, contains 55,035 names, being 498 in excess of those in the issue of the previous year. The increase of names is quite unevenly distributed among the seven sections of the directory. In Wales (—19), Scotland (—32), Ireland (—166), and the Services (—5) there has been an actual decrease, the extent of which we give in parentheses, more than counterbalanced by the surplus of 73 names in the London list, 308 in the Provincial list, and 339 among Practitioners Resident Abroad. An analysis of this changing distribution would throw interesting light on the trend of medical practice in our days. Apart from these changes, which increase the total bulk of the book by only 16 pages, the directory is little altered. The passing of the Local Government Act has involved the disappearance of the familiar heading "Metropolitan Asylums Board," and the omission of the words "poor-law" and "infirmary" as applied to general hospitals. Once again we congratulate the publishers on the vigilance and enterprise which has produced something unique among the directories of the world. The addition of an alphabetical index covering the names in all sections of the directory would make it a perfect work of reference. The publishers are Messrs. J. and A. Churchill, and the price is 36*s*. net.

THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—I desire to remind those who find it essential to know whether a practitioner is *legally* qualified or not, that in order to facilitate their work the Council publishes an office edition of the Medical Register printed on inexpensive paper, and bound in boards. This edition contains precisely the same names and lists as the official edition. It is issued from this office at a special charge of 10*s*., post free, but no copies can be issued unless they are ordered and paid for prior to Dec. 31st. I shall be happy to send an order form upon application.

The Medical Register is the official publication issued under the Medical Acts, and contains the names of all legally qualified practitioners. There is no other publication which takes its place. The Council also issues each month a list of additions to and deletions from the Register. The charge for these will be furnished upon application.

I am, Sir, yours faithfully,

NORMAN C. KING,
Registrar.

General Council of Medical Education and Registration of the United Kingdom, 44, Hallam-street, London, W., Dec. 1st, 1930.

A SANITARY TOILET DEVICE.

THE Salvas Toilet Roll (made by Messrs. Salvas, 65a, Fenchurch-street, London, E.C. 3) consists of two layers of paper. The outer layer, which is thin and shiny, is merely a waterproof protection for the hands, but the inner layer, resembling compressed cotton-wool, is both soft and absorbent, without being fluffy. This inner layer can be moistened and the paper can thus be used as a clean damp sponge without soiling the fingers. The accompanying illustration shows the Salvas Sanitary Toilet Requisite, which is a convenient apparatus for moistening small sections of the paper as they are wanted. The end of the roll is drawn upwards over a cylinder containing about a pint of water. The top of the cylinder is open, and by means of a small roller, controlled by turning a knob, the paper is lightly damped but not saturated. An antiseptic—e.g., the Salvas disinfectant concentrated pine tablets—can be added to the water.

The toilet is, of course, completed with a small dry piece of the absorbent paper, but there are real and obvious advantages in beginning with soft and damp application, and Salvas paper is excellent for the purpose. The "toilet requisite" once demonstrated should not prove an impossible obstacle either to the unintelligent or the hasty; it may be had in many different colours and qualities at prices from 7*s*. 6*d*. to 2 guineas. The price of the toilet roll refills is 6*s*. 6*d*. per dozen, and as the paper is thick the length is below the average. But its use as a moist sponge might make it relatively economical.

ADDRESSES AND ORIGINAL ARTICLES

THE DANGER OF SPECIALISATION.*

By A. E. Barclay, M.D. Camb.,

LECTURER IN MEDICAL RADIOLOGY AND ELECTROLOGY IN THE UNIVERSITY OF CAMBRIDGE.

I believe the Greek philosophers held that no man of education should specialise—"nothing in excess" is a Greek proverb—it was for the slave to specialise, and for the man of wider knowledge and broader outlook to criticise and appreciate the work in arts and crafts in which his slaves were specialists. The outlook upon specialisation to-day has changed, but the underlying principle is the same—a very broad basis of education is essential for critical appreciation of specialised knowledge.

Specialisation has become essential because the receptivity of the human mind is limited. It is said that the specialist is a man who knows more and more about less and less, while the practitioner is one who knows less and less about more and more. And therein lies the danger. The ordinary man who becomes a specialist is working at some small aspect of a problem, at filing and polishing one cog in a wheel in a chain of wheels in a vast and most complicated machine—is it likely that he can see in its proper proportions the value of the little bit of work that he is doing? And it is this danger that runs through the whole of those branches of science about which I know anything.

In the medical curriculum the student who goes straight through the course spends two years on pre-medical subjects, physics and biology, two years on anatomy and physiology, with dissecting-room and laboratory work, and three years in clinical studies in the hospitals. It is nearer eight than seven years before a student can qualify, and it is not till he has qualified that he is able to take responsibility and see his life-work from an angle that is far different from that of examinations. The medical student of to-day has to start his pre-medical training in the last two years of his school life—when and how can he get the general education on which to base his long years of purely specialist study?

Practically every teacher aspires to be a specialist in one form or another. His research record rather than his teaching ability is the keystone to his appointment. His living interest lies in his special research—his bread and butter is in the heavy burden of routine teaching. When a teacher is placed in charge of a special department it must be his aim and object to further its interests. Naturally he will be proud of the work that is done in his department, and he will not underestimate its importance. He will attend meetings and congresses where he will talk his own particular "shop"; and there will meet others who, like himself, have long come to the conclusion that this particular branch is the one that really matters in the curriculum. This, stated with some exaggeration, no doubt, is the natural attitude that has come out of the multiplication of specialties, each in its own department, each in its isolated building if it can get one, each with its own journals, and often with its own jargon. And if this man has to outline a section of a course for students, whether of medicine or anything else, he is not likely to minimise the importance of the knowledge that his department can teach, or to give way to other subjects which are of secondary importance in his eyes.

Little wonder that the medical curriculum has grown unwieldy, that the course cannot be completed in less than seven to eight years after matriculation, and that a further year is threatened. And withal it is sometimes forgotten that to the medical student the most essential of all studies is the study of man. He can be taught a great deal, but this one thing he has to learn for himself. No teaching, except that of Mother Wit, can give him the wisdom that leads to an understanding of human nature—call it psychology if you will, so long as you do not think of it in terms of time reflexes and other laboratory methods. The student has little chance of developing this essential part of his training, except by contact with his fellows, until he gets into the wards. Yet this is his life's work.

The Fallacies of Anatomy and Physiology as now Taught.

Most students notice that there is a very wide gap between the subjects of the second M.B., the anatomy and physiology, and the practical medicine of the final years. In teaching the anatomical and physiological sides of radiology, I meet men who have been qualified for a few years, and nearly all of them seem to have forgotten these subjects to an astonishing extent, yet, so far as I can tell, they do not seem to be any worse or better physicians on that account. Surely there is something far wrong that this should be the case! I believe the trouble lies in the fact that these have become specialist subjects, taught by specialists, in departments that are separated from those in which the practice of medicine goes on.

This was brought home to me by a new text-book published just a year ago that came into my hands recently. One knew vaguely of the wonderful progress in physiology, out of which have come some of the greatest advances in medicine—insulin, liver extract, hormones, and vitamins. I turned the pages of this book to see how radiology had affected the teaching of what I had learned of the physiology of the alimentary tract. Looking to the name index in this attractive volume, I found a list of 360, whose work is acknowledged, but not a single one who has studied the human alimentary tract by radiological methods. In vain one sought for such names as Rieder, Holzknecht, Hurst, Forssell, Haudek, Case, Carman, Haenisch, Kaestle, Groedel, Akerlund, Alvarez, Berg, Scott, Holland, and all those others we know so well in radiology. And when one examined this book, one was staggered to find in this section the same physiology that we were taught 30 years ago or more. The whole subject that the radiologist knows so well is a blank! The experiments of Beaumont 1833, "The Backwoods Physiologist," on Alexis St. Martin—he of the gunshot gastrostomy—still hold the field! The stomach is still described as normally a bilocular organ during the process of digestion, and Beaumont's actual descriptions are reproduced! The mechanics of digestion, the importance of which probably only a few radiologists yet fully realise, receive scant attention.

* Extracts from the Silvanus Thompson Lecture delivered before the British Institute of Radiology incorporated with the Rontgen Society on Dec. 5th, 1930. The lecture will appear in full in the British Journal of Radiology.

Peristalsis is noted only in a few passing words; the extraordinary and extremely important "mass movement" of the large intestine, first described 19 years ago, is not even mentioned. In fact, the intestinal tract is just the same inert chemical test-tube that it was 30 years ago, in which everything takes place according to formulæ. After many years' observation of human stomachs of all types, one has no patience with such armchair pictures based on the study of one abnormal subject. The futility of such conceptions has been obvious for the last 20 years or more to any person who took the trouble to watch the opaque meal examinations that are conducted by thousands every day in our hospitals.

More than 30 years ago W. B. Cannon, then a young physiologist, investigated the intestinal tract of animals with bismuth and paved the way for human investigation. He even applied the method to man, but very soon returned to the physiology department and to animal experiments. So far as I know, no other physiologist pursued the subject, and it was left to radiologists, men who had no special knowledge or training, and who were overburdened with routine work, to hammer out for themselves as best they could the normal and abnormal mechanism of the human alimentary tract. Apparently, there are still physiologists who do not know of the pre-war work that has been done. In all good faith they go on teaching bilocular stomachs, acid control of the pylorus, and other relics of a bygone day when speculation passed for knowledge. Our medical students have the right to be taught such known things as will prepare them for the practice of medicine. Conversely, they surely have the right to be delivered from the necessity of being taught things which are obviously wrong, or which are merely pious armchair hypotheses.

To-day radiologists rely implicitly on disorders or irregularities of the mechanics of the intestinal tract to guide them to a diagnosis with a degree of accuracy that is extraordinary, especially considering that they are dealing only with shadows. Lord Moynihan recently said that the X ray examination of the stomach is of more value than all other methods put together.

I am not suggesting that there are no fallacies in the opaque meal method of investigation, but what I do maintain, as the result of very many thousands of examinations, is the futility and certain inaccuracy of observations based on a limited number of individuals. For this reason it is perhaps providential that no serious attempt has been made to do radiological work in the laboratories, but it makes one more than sceptical of the chemical work on the alimentary secretions that emanate from such laboratories. This must also be open to the same fallacies—not one, or ten, or a hundred observations can justify definite conclusions about either the chemistry or the physics concerned. If gross variations of form and function are possible within the limits of normality, how can we dare to pretend scientific accuracy from animal or test-tube experiments of such variables as human gastric and intestinal secretions, that we know are subject not only to mental and physical fatigue, but to every emotion—as was shown 100 years ago by Beaumont—and to every sensation that finds expression in the human body?

The book I have referred to was written for medical students, and, as I have said, it contains sections that are not only futile but utterly misleading in an extremely important department of physiology. Is this book typical? Perhaps not, but that such an important section could appear and pass without comment in the glowing reviews of two editions that I have seen shows that the vitally important physiology that has been revealed in X ray departments has not even yet been noted by some physiologists.

No branch of science can afford to stagnate—it must progress to justify its existence, and in such subjects as anatomy and zoology the only way of progress used to be in the further development of the descriptive methods that have been handed down for generations. This extended to comparative studies and other fascinating branches, but of the descriptive type and all dealing with form, and that form being the dead subject that, as regards the internal organs, is as different from the living as death from life. The living conception of human anatomy and physiology that is opened up by radiology presents a new outlook on such subjects. Roughly, anatomy deals with form, while physiology is confined to function. To the radiologist and to all who study the living subject, this or any other artificial division is altogether impossible. The radiologist cannot study form without considering function, nor can he consider function without taking form into consideration. From the radiological point of view, anatomy and physiology cannot be divorced from each other or from pathology; the one slides imperceptibly into the other, and there is a wide border-line that is common to each. To divide in order to classify may be convenient, but it is wrong, unnatural, and leads, in practice, to a mistaken conception. May I take a simple example from the appearance and behaviour of the stomach? In our anatomical conception, we describe the organ in one state as J-shaped, and at the same time we note that the tonic action—function or physiology—of its muscle is good. Perhaps the patient turns faint or is startled, and the whole description goes wrong—the stomach changes its shape and sags down because the tone (physiology) of the muscle has altered. The form and the function of this and other muscular structures are interdependent. Radiologically, at any rate, there is no dividing line in this section between anatomy and physiology. There is also a point where physiology and pathology melt imperceptibly into each other, and the further we trace things back towards the elements, the more impossible it becomes to draw a dividing line and say where the normal cell changes its character and becomes pathological. So far as radiology is concerned, these three essentials of all medical training, anatomy, physiology, and pathology, are so bound up with each other, and so intimately concerned with the diagnostic side of radiology that it is little short of folly to attempt to separate them, and regard them as separate subjects.

In other biological sciences, some of which enter the early stages of the medical course, radiology offers the same vistas of progress. In zoology, for instance, a fertile study would be a comparison of the mechanism of digestion through the animal kingdom, leading up to man.

The Radiologist in the University.

The four great biological subjects—zoology, anatomy, physiology, and pathology—are housed in separate departments, each with its own head, each ploughing its own furrow. Are those furrows converging on one object—the preparation of the medical student for his life's work?

Radiology must come into all the biological sciences, whether human or animal. Here and there we find an X ray apparatus in an anatomy or physiology department, for the most part unused for lack

of a competent radiologist. There are exceptions, but, speaking in general, radiology is not yet employed in the biological sciences where it could bring the same tremendous incentive for progress that it has already supplied to clinical medicine. The need for university departments of radiology is evident. If attached to any one of the existing sections—e.g., anatomy or physiology—they are not likely to fulfil their destiny, unless the director of the section has a breadth of view that takes his subject roaming into preserves that, by tradition, belong to other departments. To the radiologist there is no artificial barrier between sections. Just as in a hospital, the department of radiology should be a meeting house where different interests converge, draw from each other's store of knowledge to mutual advantage. In a sense it should not be self-contained, but rather a service department that is provided to meet the need of each research as it presents itself. Here the accumulated store of combined experience is at the service of all. But it must be something far more than an X ray apparatus and equipment which can be bought for a few hundred pounds. The services and coöperation of an *experienced* radiologist (by that I mean a man who has himself examined thousands of patients and not just a scientist who has taken a medical qualification) should be at the disposal of all biological departments of every university, so that living human and animal problems could be worked out, apart from the rush and distraction of the hospital X ray services.

Scientific and especially medical education has, like Topsy, "just growed." Even if we see possibilities of improvement, we are hampered not only by the conservatism of tradition, but by the personnel, buildings, and machinery that have grown up in the course of centuries. A place, however, must be found for radiology, for our students must be taught something of the subject. The question is how much and by whom is it to be taught? Some maintain that all medical students should take a course of lectures, and also a period of actual service in an X ray department, while some surgeons and physicians hold that all the radiology the student needs should be taught by them. To me it is clear that every student should in the first place be taught the radiological aspects of anatomy and physiology in these departments. He must also learn the uses of radiations in diagnosis and treatment, and what he can expect in the way of assistance if he calls in a specialist. This knowledge should be imparted by the radiologist himself in a short course of, say, eight lectures, but there is no need whatever to teach students anything of the very highly specialised technique. In many universities such a course is already in the syllabus. It is yet one more set of lectures added to the curriculum! And every special service argues the same way, wanting some of the student's time. In each instance the same principle might be applied as in radiology—all technique might with advantage be eliminated except for those who intend to specialise. Why should the student learn masses of detail, which seem to have no practical application, not only in physiology and anatomy but in every subject? Why should we tempt providence by making all learn the technique of surgical operations which only a few will ever have the skill or experience to perform efficiently, the detail of chemical, bacteriological, and other technique, only a fraction of which they can possibly use? Each specialist is trying to teach as much as possible of his own subject to men who, in nine cases out of ten, will neither have the opportunity nor the wish to practise that particular specialty. For that one man in ten the teaching is too little to be of real value; for the other nine, it is just so much detail to cram up for examinations. I believe that the medical student could be adequately prepared for his life's work in a far shorter period. It is, however, only by coöperation, placing the common good before departmental interest, that the student's burden can be reduced without impairing efficiency. Each branch needs to know more and to see more of the work of the other branches, so that they can coöperate effectively in the team. The danger of specialisation is, of course, well recognised, and steps are taken to combat it in various ways. Team-work, however, seems to be the only practical solution.

The Specialist Practice of Radiology.

Now let us look at the other side of the picture. How is the specialist practice of radiology shaping its course? Is it, like so many other branches, endeavouring to build walls around itself, or is it widening out its sphere of influence and usefulness? We have our own journal; that is inevitable, for many of our contributions lie on the borderland—they are often too physical for publication in the medical, and far too medical for the physical journals. Our journal is essential, fills a unique place, and must always be an integral part of radiology. But radiology has become ubiquitous, extending into every branch of medicine. We can hardly take up a journal that does not contain some radiology. Whether we like it or not, radiology, even specialist radiology, has become diffused—the radiologist, loyally backed by the physicist and manufacturer, has laboured to develop his special methods, and one after another they are being absorbed into the grasping folds of other special branches of medicine. These, having learned from the radiologist the technique and value of the methods he employs, quite naturally and without the slightest shame take them for their own use. I fear it is no use acting the part of the small boy whose toy is taken from him by a bigger boy—"that is my toy," says he; "that *was* your toy," says the big boy and just walks away with it. One by one we are seeing our toys taken—dental, orthopædic, fracture, dermatological, urological, tuberculosis work, gastric work, radium—and the radiologist is left in different centres with just those branches of his art that have not been claimed by the stronger boys, who quite often make but a sorry show of this acquisition. Some of this loss is inevitable, and we might as well face it, but a large part of it could be avoided. If the radiologist is really competent and delivers the goods, the highest class of goods at a fee that is reasonable, he will almost invariably retain the practice in which, if he is expert, he will easily beat his untrained competitors—but he must be a real expert. There is room for the first-rate clinical radiologist anywhere; the second-rater—in radiology as in all else—is liable to go to the wall.

It is evident, however, that even if he would the radiologist cannot erect a wall around his preserve, and, in fact, the only fence, or self-defence, he can put up is his mastery of his own sphere of medicine, a sphere that is, I venture to say, wider than any other in the whole range of medical practice. Specialisation has been let loose and has abundantly justified itself. What attitude do we, as radiologists, take in the matter? The answer as regards diagnostic radiology is simple—although we happen to work in a laboratory we are essentially clinicians, and we must be a clinical service department, self-centred and self-contained only because our methods are so highly specialised

that centralisation of our service is the only way to progress and efficiency.

Radiology covers such a wide field and one that is still extending so rapidly that it is now impossible for any radiologist to be anything other than a general practitioner in the subject and to specialise in certain branches. Radiotherapy alone, for instance, has become a subject of such proportions and depending on such a variety of laboratory research that, unless he specialises in therapy, the radiologist cannot keep up with progress in this one important branch. Therapy, therefore, cannot but be a special service department drawing its cases from every other department, the responsibility for the special treatment being that of the radiotherapeutist.

The radiologist does not aspire to be a physician, a surgeon, a gynæcologist, a physiologist, an anatomist, or to be an expert in any of the branches he touches. His unique position as the first medical man to observe X ray appearances has forced him, however, into pioneer work in many fields in which he has had to find his own way. History repeats itself, and we think of the pioneer enthusiasm of our forefathers for leeches and bleeding; of another generation for indiscriminate gastro-enterostomies, wholesale dental extractions, tonsil and adenoid operations, and in the present generation, ultra-violet rays, vitamins, and, may I add, the surgeon's discovery of radium, &c. In our own particular sphere it was the radiologist's misfortune, not his fault, that he had to plunge straight into pathological studies in hospital practice before the normal had been investigated. This has had serious consequences, and each of us can think of mistakes that were due to want of knowledge of the normal and want of correlation with the clinical. The worst and most extensive blunder of this kind and one that had and still has very serious consequences was the misinterpretation of the shadows at the root of the lung. For a period normal shadows were interpreted by some observers as definite evidence of hilum phthisis. Subsequent history has proved the diagnosis to have been wrong in the vast majority of cases, but on the strength of this X ray diagnosis men were exempted from army service by the hundred, and others were sent to an invalid life and placed under the heavy disability of being tubercle suspects. The clinical diagnosis of the condition by the physician was on too weak a foundation to refute the radiological findings and, naturally, there were no post-mortems. It took years of scepticism followed by ridicule before we realised that this "X ray disease" was nothing more than a very serious error of judgment on the part of those who studied the chest by X rays without adequate experience of the normal. Yet the blame should hardly rest with the radiologist, for he had no foundations in either anatomy or physiology that had been corrected to X ray or living standards.

The same thing applies to the alimentary tract—the study of pathology has preceded the study of the normal. Many an abdomen has been opened because of a reported kink, a dropped stomach, or dropped flexures of the colon, which were, for the most part at any rate, mere variations of the normal. We still see reports on constipation in which the radiologist talks of a dropped transverse colon as the cause of the trouble. When he has seen the stomach and the colon functioning normally in spite of the most weird anatomical dispositions, he will cease to jump to the conclusion that these things are the most probable, but rather the least likely cause of the symptoms.

It was years before even the radiologist really appreciated the fact that the stomach and all the alimentary tract was a living muscle, capable of extraordinary variations within the normal, and, naturally, he attributed to some of these variations the liability for symptoms from which the patient suffered—he was just finding his way, blazing a trail in new country where there were no signposts to guide him.

Those were great days of adventure for the radiologist as he explored unaided into the unknown that was revealed by X ray methods. The present position of radiodiagnosis of chest and alimentary conditions is something of which he may be justly proud. There is still a long way to go. But that is no reason why what has been done and really proven should not be accepted by other departments. Radiologists have established certain facts by the study of an enormous bulk of human material to which no other department has had access. Only by such concentrated study is it possible to build up a true conception of the living anatomy and physiology.

VALVULAR DEFECT IN RELATION TO VARICOSIS.

AN INVESTIGATION OF THE VALVULAR MECHANISM OF THE VENOUS RETURN FROM THE LOWER LIMBS.

BY W. TURNER WARWICK, F.R.C.S.ENG.,
SURGEON TO OUT-PATIENTS, MIDDLESEX HOSPITAL.

VARICOSE veins are generally admitted to be of congenital origin, although authorities differ as to whether the inherent factor is weakness of the vessel walls or defect in the valves. The observations that have been made to support the former theory depend mainly on histological changes which are difficult to interpret and on inconclusive experiments. The latter theory offers a more promising field for direct observation, and the experiments recorded below have been made to determine the presence or absence of valves in a series of young subjects assumed to include normal as well as varicose types.

Anatomy of the Veins.

Before considering these experiments a brief review of the accepted anatomy of the veins of the lower limb is essential. This is best considered under the following headings: (1) superficial system; (2) deep system; (3) perforating system. The superficial and deep systems need little further description beyond that given in text-books, but the anatomy of the perforating channels which connect the superficial and deep veins must be further detailed.

Perforating veins.—The main venous trunks of the limb form part of the deep system, and the superficial veins drain into them through the perforating channels. The perforating system, therefore, is of supreme importance to the superficial veins, and yet it is the part of the venous path which has received the least attention, especially of recent years. Certain of the perforating veins have acquired increased importance during evolution in proportion to the size of the superficial channels related to them. Thus the preservation of the terminations of the main internal and external saphenous veins is of some advantage to the return circulation, provided that they are adequately valved. If they are not, they may be ligated with advantage, as the remaining perforating veins serve to carry on the needs of the superficial

circulation. Briquet, more than a century ago, drew attention to the relation of the superficial varices in the leg to perforating veins.

"À l'endroit où la phlébectasie est la plus prononcée, il y a des communications très-larges avec les veines profondes, que sont larges à l'endroit d'où part la branche anastomotique; mais qu'ils reprennent leur calibre."

The perforating veins which have attracted most atention are the main ones of the *internal saphenous* in the leg and thigh (Fig. 1). These are direct and are found: (1) At the junction of the middle and superior thirds of the leg. Here a large important channel connects the internal saphenous system—usually the trunk—with the posterior tibial veins, running close to the tibia through the muscular attachment. (2) At the junction of the middle and distal thirds of the leg. This is usually smaller. It connects the internal saphenous and the posterior tibial. (3) Above the knee there is usually one anastomosing vein between the internal saphenous and the deep vein. This is small and is usually placed in the middle of the thigh.

The perforating veins of the *external saphenous* (Fig. 2) are indirect in the calf, as in this situation they unite with the trunks of the chief muscular veins (1) About the level of the junction of the upper and middle thirds of the leg a branch runs from the external saphenous vein through the deep fascia to end, as a rule, in the medial gastrocnemial vein. (2) A superficial loop of secondary size runs from the external saphenous vein over the lateral gastrocnemial belly to take part in the formation of the superficial external femoral vein. From this loop or from the main vein one or more perforating vessels run to the external gastrocnemial vein. (3) About the middle of the leg an indirect perforating vein from the trunk of the external saphenous traverses the soleus to join the soleal vein before terminating in the posterior tibial vein.

In the lower third of the leg one or more direct perforating twigs pass from the external saphenous, piercing the deep fascia to end in the posterior tibial vein.

COMPARISON OF VENOUS RETURN IN ARM AND LEG.

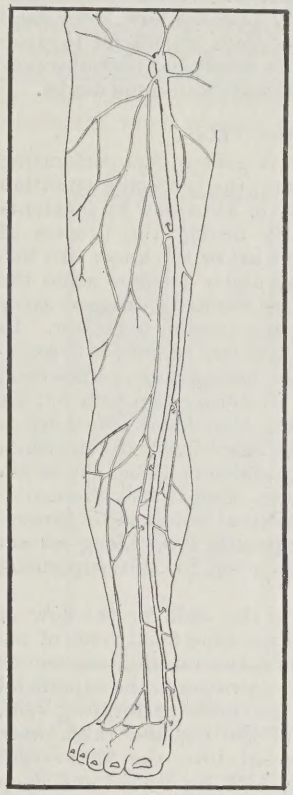
Briquet held that during contraction of muscles all the blood in the lower limb passes through the superficial veins.

"Toute passe dans les veines superficielles, ce qui démontre par l'influence des contractions musculaires sur le jet du sang, que dans la saignée on voit s'enlancer fort loin chez les gens robustes au moment où se fait la contraction."

This still appears to be a general impression, which is strengthened by analogy with the venous return in the upper limbs. It is common knowledge that in the arm increased flow along certain superficial veins is produced by contraction of the forearm muscles, use being made of alternating movements of clenching and unclenching the hand in collecting blood for transfusion from a donor. The superficial median and the deep median join and bifurcate immediately to form the cephalic and the median basilic veins. Blood is drawn usually from the median basilic. The advantage of the alternate clenching and relaxation is that the contraction of the muscles of the forearm tends to empty the deep veins, some of the blood reaching the superficial veins through the deep median. The needle or cannula should therefore be distally directed and is inserted downwards from a point sufficiently high up the median basilic to ensure that it does not obstruct, kink, or project distally to the deep median. Otherwise this vein does not convey its portion to the superficial veins, so that the value of the pumping action of the muscles is diminished. It might theoretically be possible that the same increase of flow of blood into the superficial veins of the leg occurs during the period of contraction of the calf muscles, the forces of pumping and suction from muscular contraction and relaxation playing an organised though complicated part in the blood return through alternate superficial and deep routes.

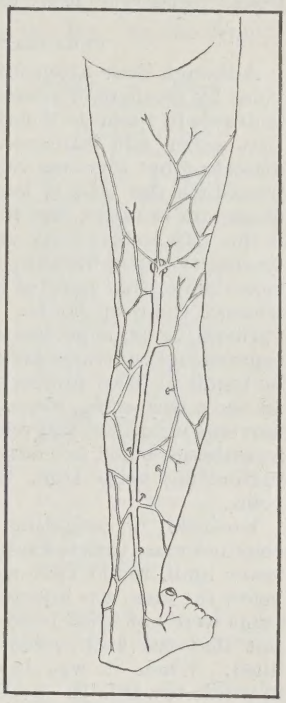
Comparison of the veins of the arm and leg reveals the following points of difference. In the arm venæ comites accompany each artery to the root of the limb, where a single efferent channel is formed in the axilla. The axillary vein drains the blood directly not only from the entire superficial surface of the arm but also from the shoulder girdle. In the lower limb a single main efferent channel (the popliteal vein) is formed at the knee. Blood from the superficial lateral aspect below this level reaches the efferent trunk here, while the internal superficial areas are drained into the vein at the root of the limb, together with the blood from the superficial veins of the thigh above the knee. Moreover, the greater part of the blood from the pelvic girdle and from the thigh returns via a different channel, the internal iliac. Blood in the median basilic is at so short a distance below the level of the heart that the aspiration of the chest during inspiration and the force of vis-a-tergo will together be more than adequate to account for the return. In the lower limb, where varicose veins occur, the difference of level is considerable and the mechanics of the venous return call for careful consideration. With such noteworthy differences it is possible, therefore, that the perforating veins have a different action in the upper and lower

FIG. 1.



The internal saphenous system. The majority of the perforating veins arise from the main trunk, but some from secondary branches.

FIG. 2.



The external saphenous system. General outline of the communications and perforating veins.

limbs. Indeed, Verneuil definitely stated as a result of anatomical observations that in the leg the perforating veins were normally valved to prevent flow from deep to superficial veins, but that in the upper limb flow from deep to superficial veins was normal. The majority of subsequent writers agree that whenever valves are found in the perforating veins of the leg they are arranged to prevent flow from deep to superficial veins (de l'Aulnoit, Le Dentu, Luschka) and my own observations are in accordance with this. Some investigators, however, have failed to confirm this finding. Klotz said that the majority of perforating veins were unvalved. When valves are present, in some cases they prevent flow from deep to superficial and in others from superficial to deep veins. It must therefore be concluded that observations by dissection leave the matter in some doubt.

PERFORATING VEINS.

Although little attention is paid to the perforating veins by teachers of anatomy, the surgeon's attention is drawn to them very early in his career by incidents that occur not infrequently during the process of dissecting out tortuous veins below the knee. In this procedure the vein is kept under tension while the dissection is made, and is occasionally dragged away if the vein wall is weak or the tension too great. In tracing the open bleeding ends left behind, it is sometimes found that most of the hæmorrhage comes from beneath the deep fascia. If, during an operation for varicose veins, a perforating vein below the knee is isolated and cut across before ligation, it will sometimes be found to bleed profusely and sometimes not at all. In the varicose leg, therefore, even in the absence of movement and the full relaxation obtained by general anæsthesia, blood not infrequently flows along certain perforating veins from the deep to the superficial veins.

Kosinski, investigating in the cadaver the flow of coloured mass injected into the superficial veins of the lower limb, found that when the internal saphenous below the knee was injected downwards the superficial veins were not filled below the main perforating vein, but that the deep veins of the leg and thigh were filled. When it was injected into the same vein upwards towards the knee, both superficial and deep veins were filled. The saphenous, therefore, not only empties itself through the main termination, but also through the perforating veins. This is true both in the normal and in the varicose limb. If a distended segment of a varicose or normal vein in the calf is isolated between two rubber bands and the patient asked to walk up and down the room, the full superficial vein segment is often emptied. The suction of muscle relaxation is the force presumably responsible for the emptying. It has recently been shown by Gaugier that if an opaque solution, such as lipiodol, is injected into a varicose vein, this substance can be seen under X rays to have reached the deep veins after a few movements of the calf, and using the same method McPheeters has made extended observations on venous flow.

It may, then, be regarded as established that under conditions of movement blood flows from the superficial to the deep veins in varicose and non-varicose veins, and that in varicose veins, therefore, flow may take place in either direction according to circumstances.

DISPOSITION OF VALVES IN PERFORATING SYSTEM OF LEG.

It still remains to be settled whether flow from deep to superficial veins ever occurs in the normal leg under suitable conditions of rest or movement. Direct observation under local anæsthesia seemed to offer a ready method of definitely settling the question. As, however, no opportunity presented itself of making this apparently crucial experiment on the living subject, preliminary observations were made by an indirect method in the post-mortem room.

Method of Investigation.

A series of experiments was carried out on the bodies of young subjects below the varicose age and of young adults without obvious varicose veins. After preliminary observation on the limitation of flow of coloured fluid injected intravenously at various sites opaque fluid was substituted and skiagrams were taken at various stages. These experiments eventually proved that a single, apparently conclusive, direct experiment in a supposedly normal subject might have given misleading information, and incidentally afforded an explanation of the divergence of opinions among anatomists.

The first experiment gave support to the possibility of flow from deep to superficial veins. In the body of a young unmarried woman, free from superficial varicosity, the posterior tibial, anterior tibial and the external and internal saphenous veins were dissected out at the level of the ankle joint, and a cannula inserted in each. The femoral vein above the termination of the saphenous was dissected out and opened. The deep and superficial veins were then syringed with water through the cannulas in all the opened veins at the level of the ankle until the flow from the femoral vein was clear. By this means any clots which might prevent the valves from functioning were removed. The internal saphenous at the knee and the superficial veins along the line that represents the surface marking of the anterior tibial veins were now exposed and opened. Coloured fluid of approximately the same consistency as blood was then syringed into the posterior tibial at a low pressure. This flowed not only out of the femoral vein, but also out of the internal saphenous and even from the small perforating veins between the anterior tibial and the superficial veins on the front of the leg. The same result was obtained when the anterior tibial was injected.

The results of this experiment suggested that all the veins of the leg were in free communication, like the channels of a plexus, and that the blood could pass freely backwards and forwards along perforating and deep communicating veins according to the dictates of muscular contraction or other forces. On consideration this seemed to indicate that either a very crude method of maintaining an orderly circulation was present, or else a very elaborate one the mechanism of which was not obvious. Repetition of the same experiment in a number of apparently normal young subjects showed that this free communication from deep to superficial veins was present in only a small proportion of cases, and the consideration of obscure mechanisms was therefore unnecessary.

Further investigations have shown that in the majority of subjects—a group considered to represent the normal type—the veins are valved in such a manner as to ensure absolute efficiency of the venous return from the lower limb. In the remainder incompetence of valves in definite regions gives rise to definite types of varicosity.

Twenty-eight more cases of young subjects without any clinical sign of varicose veins were investigated in this way. In 25 of these, coloured fluid injected into the anterior and posterior tibial veins did not reach the superficial veins even when the pressure of the injection was raised considerably after ligation of the femoral below the point of entry of the saphenous vein. (See normal or congenitally non-varicose type, Figs. 4 and 5.)

VALVULAR DEFICIENCY IN PERFORATING SYSTEM.

1. Three cases out of 28 were distinguished from the rest by the incompetence of the perforating system in connexion with the internal saphenous

system. They will be referred to as the *congenitally varicose internal saphenous type* (Fig. 6). These three cases were investigated by substitution of an opaque for the coloured fluid, the injection being watched under the screen and the results recorded by films from time to time. In this type there is leakage from the deep main veins along certain perforating veins of the internal saphenous, but all other branches of the deep veins are adequately valved at their terminations.

2. Of the remaining 25 cases ten were investigated by X rays in the same way. In eight of these fluid injected remained confined to the main venous channels, and there was no escape into any tributary, no matter how high the pressure of the injection was raised after ligation of the femoral vein. (See Figs. 4 and 5). In two cases out of the ten, reflux occurred into muscular branches of the calf (Figs. 7 and 8). The trunks of these muscular veins, as has been noted above, receive the perforating veins of the external saphenous system. There is still some protection of this superficial system from reflux from deep veins, as in one of the cases the injection fluid did not reach the system whatever pressure was reached in the main veins, and in the other case the fluid slowly entered it when the pressure was raised to a very high level. The external saphenous has, however, only a small proportion of its normal protection, and the group in which there is muscular vein incompetence may also be regarded as one disposed to varicosity of the external saphenous system. It will be referred to as the *congenitally varicose external saphenous, or calf-muscle type* (Fig. 7).

After eliminating these two groups the majority of the remainder will represent the normal non-varicose type.

DISPOSITION OF VALVES IN SUPERFICIAL AND DEEP VEINS.

Before defining the normal non-varicose type it is necessary to note how the main superficial and deep veins are generally valved, and to see if any departure from normal likely to give rise to disability can be readily demonstrated.

The following observations by various writers will serve to summarise our knowledge of the disposition of valves in these veins.

Superficial system.—Valves in the great saphenous vein were described in his work, "De venarum ostiolis," by Fabricius, who noted, among other laws governing the disposition of parietal valves, that they are found almost constantly below the entrance of a tributary. According to Bardeleben the principle on which the distribution of valves in superficial veins depends is as follows. Fundamentally a vein consists of a number of divisions segmentally arranged, each division being formed by a piece of cylindrical wall, a conical widening (sinus), a tributary vein entry, and a bicuspid valve. The general rule according to this author is that "distal from every tributary lies a valve, proximal from every valve is a tributary entry." Exceptions are only apparent, and due to disappearance of valve or tributary. Kosinski has shown that the superficial vein is valved below its junction with important perforating veins. Klotz found no valves in cross-anastomoses between veins of equal size; between veins of unequal size there are valves so directed that the blood flows from smaller into larger.

Deep system.—Sappey ("Traité d'Anatomie," 1850–64) stated:—

"Les valvules sont plus nombreuses dans les parties du système veineux où le sang coule contrairement aux lois de la pesanteur, plus dans les membres inférieures que dans les supérieures, plus dans les veines de petit calibre que dans les veines volumineuses, plus enfin dans les veines des muscles que dans celles de tout autre organe. Les veinules intra-musculaires en sont en quelque sorte criblées."

"Les valvules seraient plus abondamment répandues dans les veines superficielles que dans les profondes, suivant Béclard et Meckel. Blandin a refuté cette erreur en montrant que les veines intermusculaires dont les parois sont plus minces et plus souvent déprimées par le jeu des muscles, possèdent, ainsi que la physiologie, pouvait le faire prévoir, plus de valvules que les veines sous-cutanées."

H. de l'Aulnoit pointed out that a valve dominates the venous system of the lower limb (femoral valve), and said that this is the most constant of all. This valve is not, however, so constant as the one below the termination of the deep femoral vein. He showed that the deep veins possess more valves than the superficial and that the muscular veins surpass the two. There are less valves in the deep trunks of the thigh than in the main venæ comites in the leg. In the femoral

he found three valves, in the popliteal one, but as many as 19 in the posterior tibial, and 11 in the anterior tibial veins.

The following investigations bearing on valvular distribution were made in a number of cases. The results recorded indicate the normal arrangement of valves in the superficial and deep veins (Fig. 3). The experiments described have, however, been selected mainly because they are simple of application as post-mortem room tests of incompetence of superficial and deep veins.

INTERNAL SAPHENOUS SYSTEM.

EXPT. 1.—Injection of the internal saphenous downwards from a point immediately below its termination forces the first parietal valve when the pressure is raised considerably. The next valve or two give way more readily, and then the fluid slowly begins to enter the perforating vein of the thigh and to fill the deep veins to the same extent as in Expt. 8. It does not descend the internal saphenous until the parietal valve immediately below the point of origin of this perforating vein is ruptured by the raised pressure. Conclusion: The parietal valves in the internal saphenous are usually weak, but occasionally the penultimate valve is comparatively strong. The dilatation of the terminal segment of the internal saphenous vein is probably caused by the pressure of the reflux through the saphenous termination above this comparatively strong valve. There is a valve just below the perforating branch in the thigh. This perforating branch is usually small and somewhat elongated.

EXPT. 2.—Fluid injected into the internal saphenous downwards from a point below the knee fills the saphenous vein as far as the perforating channel at the junction of the upper and middle thirds of the leg, through which it reaches the deep veins. It does not descend the internal saphenous beyond this point, but it occasionally reaches the external

saphenous system via small communicating branches. The course in the deep veins is almost entirely upwards, that in a downward direction being usually very limited by valves. Conclusion: There is a valve in the internal saphenous just below the perforating vein in the calf. Blood may sometimes flow from the internal saphenous to the external saphenous along superficial communicating branches.

EXPT. 3.—Fluid injected upwards into the internal saphenous at a point below the level of this perforating vein fills the internal saphenous and may occasionally reach the external saphenous by some small superficial cross-connexions; also, through the perforating vein, it enters the deep veins, which it fills to the same level as in 2. Conclusion: Blood in the internal saphenous may flow along the main channel to the termination, through the perforating veins into the deep system, or may occasionally reach the external saphenous. Blood reaching the deep veins is directed up the limbs and cannot pass downward.

The conclusions from 2 and 3 agree with the results given by Kosinski, but the limited extent of the flow down the leg along the deep veins in the normal must be emphasised.

EXTERNAL SAPHENOUS SYSTEM.

EXPT. 4.—Fluid injected upwards into the main external saphenous vein runs along the main channel to its termination in the popliteal vein, enters the perforating veins of this system, and also travels along the veins connecting it with the internal saphenous system. This spread is so very diverse that its demonstration by X ray is impossible.

EXPT. 5.—Fluid injected into the external saphenous downwards from a point short of its termination is soon obstructed by valves that resist more pressure than those of the internal saphenous.

MAIN DEEP VEINS.

EXPT. 6.—Fluid injected into the external iliac vein is most often held up by the femoral valve, which is placed in a well-protected position about the level of Poupart's ligament. This is often the first competent valve between the heart and the limb veins. The external iliac is frequently provided with one valve, and the common iliac occasionally has one, but in a large proportion of the cases in which these valves exist they are incompetent. Most observers deny the existence of a parietal valve between the heart and the common iliac veins. The femoral valve is very constant in position, but is absent in a small percentage of subjects. Conclusion: The femoral valve protects the limb against back-pressure from the abdomen.

EXPT. 7.—Fluid injected into the femoral vein downwards from just below Poupart's ligament will not pass into the internal saphenous, but continues down the femoral to a valve just below the level of the entrance of the deep femoral vein. It will not enter this. Conclusion: Terminal valves guard the entrances of the internal saphenous and of the deep femoral into the femoral vein. A parietal valve (deep femoral valve) is present in the femoral vein just below the entrance of the deep femoral. This is a very constant valve.

EXPT. 8.—Fluid injected into the femoral below the level of the entrance of the deep femoral most often reaches a point opposite the level of the knee-joint. This point is just distal to the entrance of the external saphenous, but fluid does not enter this vein, nor does it reach the internal saphenous system via the perforating vein in the thigh. Occasionally the fluid is stopped by a second valve near the junction of the femoral and the popliteal veins. Conclusion: A terminal valve is present at the mouth of the external saphenous and of the perforating vein in the thigh. A parietal valve (popliteal valve) is present in the popliteal vein immediately distal to the termination of the external saphenous.

EXPT. 9.—Fluid injected into the popliteal vein downwards from below the level of the knee will not enter the anterior and posterior tibial veins. Conclusion: The beginning of the popliteal vein is valved.

EXPT. 10.—Fluid injected from the superficial aspect directly into the perforating branch at the junction of the middle and upper thirds of the leg reaches the deep veins, where its flow is almost entirely upward, that in a downward direction being normally very limited. Occasionally there is at about this level a communicating branch between the anterior and posterior venæ comites, in which case both main channels are filled above but the flow in a downward direction is prevented. Conclusion: There are valves in the deep veins just below the level of the deep connecting vein. There is usually a valve in the deep vein just below the point of entrance of the perforating vein.

EXPT. 11.—Fluid injected into the direct perforating veins lower down the leg gives similar information.

N.B.—All the valves in the deep veins, including those of the terminations of perforating and muscular veins, withstand high degrees of pressure.

VALVULAR DEFICIENCY IN SUPERFICIAL SYSTEM.

Apart from the disability arising from incompetence of the terminal valves and those of the perforating veins, no striking departure from the normal arrangement of valves has been noted in the superficial system sufficient to justify a subdivision of "superficial varicose type."

VALVULAR DEFICIENCY IN DEEP SYSTEM.

Tests for efficiency of valves in deep veins were carried out in six cases, including the two of the varicose external saphenous type. In one of the six which was otherwise normal, the femoral valve was missing on one side. All the rest showed normal valving in this situation and elsewhere, except one of the cases of the varicose external saphenous type. In this case fluid injected into a perforating vein above the middle of the calf passed downwards in the posterior tibial venæ comites to the same level as that injected into a perforating vein lower down (see Fig. 8). Apparently these veins were incompetently valved over a distance of at least two to three inches. The fluid injected into the upper perforating vein was only prevented from escaping back along the lower perforating vein by the competent valve guarding this channel. The case may be recorded, therefore, as an example of the congenitally varicose deep vein type. The absence of the femoral valve is only regarded as a disability if the terminal saphenous valve is incompetent.

When the above groups have been separated off, there remain those cases in which the main channels themselves are adequately valved throughout and there is no leakage from them, either into the perforating or into the muscular veins. These constitute the normal or congenitally non-varicose type.

We find, then, in apparently normal young subjects without any sign of varicosity, the following groups: (1) normal or congenitally non-varicose type; (2) congenitally varicose internal saphenous type; (3) congenitally varicose external saphenous type (muscular varicosis); (4) congenitally varicose main deep veins type. Some subjects may possess the defects of more than one of these varicose types.

NORMAL OR CONGENITALLY NON-VARICOSE TYPE.

In about 70 per cent. of young subjects the perforating veins do not transmit rises of pressure in the deep veins to the superficial veins. In this type injected fluid remains confined to the main deep veins at whatever pressure the injection is made. High pressures were used after ligation of the femoral vein below the termination of the internal saphenous. If the pressure is raised excessively, the deep veins will burst before the valves of the perforating veins can be forced. The picture of the result of injection of the anterior and posterior tibials at high pressure is shown in Figs. 4 and 5. Here it will be noticed that, if the one vein is injected, there is no back flow into the other. This result shows, therefore, the presence of valvular protection near the termination of the anterior and posterior tibial venæ comites. There is frequently a connecting vein in the middle of the calf, in which case the picture given by injection is the same as that shown in Fig. 6, except that there is no escape to the superficial system via the perforating veins. In such cases, when the injection is made into either of the anterior or posterior tibial veins, there is no flow down the other below the connecting branch. Again the inference is the presence of valvular protection below this junction. A second communicating vein occasionally connects the two in

the lower third. The X ray appearance also suggests that the valves of the deep veins are very close-set.

The main points of the valvular mechanism in a fully protected deep venous system may be summarised as follows: (1) terminations of all muscular and perforating veins are valved; (2) terminations of the anterior and posterior tibial venæ comites are valved; (3) there are valves in the venæ comites just below the connecting veins; (4) the valves of the venæ comites are close-set; (5) the valves in the muscular and perforating, are valved to prevent back-flow. The act of relaxation from contraction produces a negative pressure in the deep veins corresponding to the muscles, and blood is drawn from the capillaries of the deep circulation and from the superficial veins via the perforating channels and driven up the deep veins by the next contraction. During alternate contraction and relaxation of the calf muscles, therefore, if normal valves are present in the deep and in the perforating veins, the deep circulation relieves the superficial system. In ordinary active movements of the leg with unrestrained respiratory actions, the return of blood from the superficial veins is effected by the suction of muscular relaxation and of respiration rather than by the pressure of the vis-a-tergo. The pressure in normal superficial veins, except in the standing inactive position, is therefore never related to the hydrostatic pressure represented by the height of the column of blood above it. When at rest in the erect position the internal saphenous route is the most direct one for the return of blood from the superficial system, the vis-a-tergo and the abdominothoracic suction through the femoral segment being the only forces at work. This route, which is peculiar to man, affords therefore a slight advantage if the terminal and parietal internal saphenous valves are competent.

FIGS. 4 5 6.

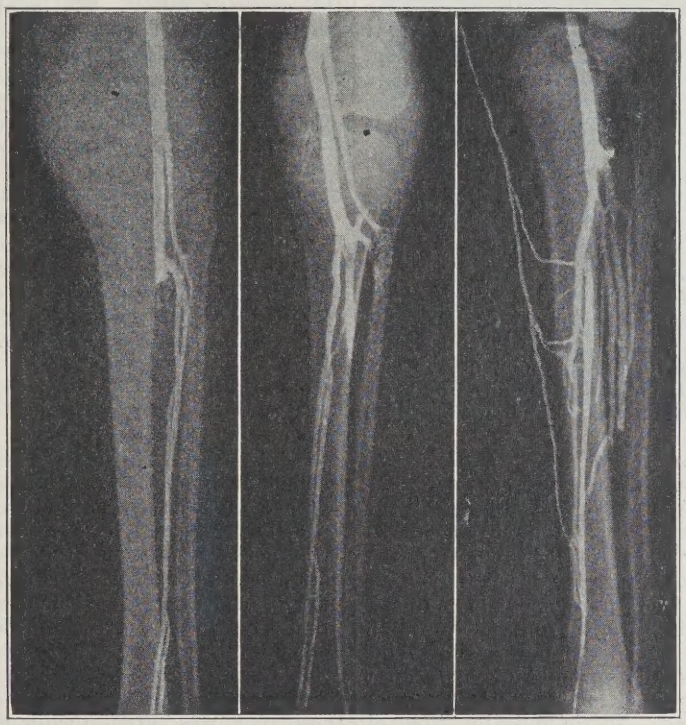

FIG. 4.—The normal or non-varicose type. Injection of anterior tibial vein with high pressure, showing competence of all veins entering the deep system. (Antero-posterior view.)

FIG. 5.—The normal or non-varicose type. Injection of posterior tibial vein with high pressure, showing competence of all veins entering the deep system. (Antero-posterior view.)

FIG. 6.—Hereditary tendency to varicosis. Internal saphenous type. Injection of posterior tibial vein with low pressure, showing leak along direct perforating veins into the internal saphenous system. The communication revealed between the anterior and posterior tibial veins is common in both normal and varicose types. (Antero-posterior view.)

venæ comites, the terminal valves of the perforating veins and those of the muscular veins are normally capable of withstanding a pressure sufficient to burst the walls of these veins.

The result of muscular contraction of the calf, if the main deep veins are adequately valved, is merely to squirt blood up the deep veins towards the heart. All other routes are protected by valves. At the level of the knee the main deep veins form a single channel which is continued up the thigh through spaces more or less directly compressed by muscular contraction. Below the knee the deep veins are arranged as venæ comites and receive the perforating channels from both internal and external saphenous veins. The venæ comites are thinner-walled, more closely valved and subjected to more direct muscular pressure. The muscular veins themselves, which have even thinner walls and closer valves, are affected most of all by muscular contraction. This increasingly close approximation of valves as the walls become thinner and the muscular pressure more direct counteracts any tendency to back-flow, and prevents waste of propulsive energy during muscular contraction.

The more distal veins are thus completely emptied by pressure of surrounding muscles into the channels above the knee, which are less directly compressed. This relation of the muscles to the veins in the leg and thigh ensures the correct adjustment of pressure and is suitable for the return of blood from the leg through the main veins of the contracted thigh. It is suggested also that contraction in the muscle starts in the fibres nearest the distal insertion, and that this arrangement also favours the upward drive of blood. Both above and below the knee all entering tributaries,

CONGENITALLY VARICOSE INTERNAL SAPHENOUS TYPE.

In three out of the 28 young subjects the perforating veins in connexion with the internal saphenous system were incompetently valved, and would not protect the superficial veins in the leg against the rapid rises of intravenous pressure that occur in the deep veins during muscular contraction. In these cases the fluid injected into one of the posterior tibial veins reaches this superficial system along the perforating veins with a comparatively small pressure. In the case shown in Fig. 6 the femoral vein is not tied, so that there is little intravenous pressure; yet the injection has reached the internal saphenous vein via the two main perforating veins in the leg.

In this type, although the deep veins and the muscular veins are adequately valved, the perforating

veins of the internal saphenous readily permit flow from deep to superficial veins. When these veins are inadequately valved the result of muscular contraction is to squirt blood through the perforating veins into the unsupported superficial veins as well as up the deep system towards the heart. In so far as the perforating veins pass through muscle they are well supported at the moment when the pressure inside them is raised, so that the effect of the primary valvular defect is only shown in superficial veins when compensation is broken down.

Inquiries into the family history of the three cases of the first group showed that in two of the three varicosis was an hereditary condition on either the paternal or the maternal side. In the third case the history of one side of the family was unknown, but the maternal side showed no hereditary tendency. These experiments were made on the cadaver, and in the earlier ones, before the importance of the hereditary factor was appreciated, the records kept in normal cases were insufficient to allow the cases to be traced and further inquiries to be made for family tendency. The question of a negative family history is, however, an important one, and detailed statistics from a further series should yield interesting and profitable results.

Two of these cases were under 12 years of age—i.e., below the usual age of the onset of varicosis. The third was 18 years of age. In all three cases of this group the upper perforating branch of the calf was incompetent and in two of them the lower one was also. In one of them the internal saphenous terminal valve itself was slightly incompetent.

The valve of a perforating vein, though not absolutely terminal, is within the deep fascia. The vein at this point is protected from stretching by the support of the deep structures. I have considered the question of valvular protection of the perforating vein within and without the deep fascia but have found no evidence that this arrangement is the basis of the divergence of this type from the normal. Macroscopical examination of the perforating veins on dissection showed usually no trace of valves, but in one instance the presence of a rudimentary or atrophied valve was noted. Microscopical sections of the superficial veins in the neighbourhood of the perforating veins could in no way be distinguished from sections from the non-varicose types at the same level. The valvular incompetence is not secondary to weakness of the wall and may therefore be regarded as the primary defect.

This type may be subdivided into three groups :—

(*a*) *Terminal valve of saphenous alone incompetent.*—No case of this group was present in this series, but it is not rare clinically as the main defect. Here the parietal saphenous valves are exposed to the pressure of the superior reflux from the terminal segment of the femoral vein. In a small percentage of cases the femoral valve is absent and there is a true abdominal reflux into the saphenous. When the whole parietal system of the internal saphenous has given way before the pressure, this reflux is demonstrable as Trendelenberg's sign. In the upright position the veins of the leg are exposed continuously to the pressure of the column above, and a feeling of weight in the legs is then a constant symptom. As the valves of the other perforating veins are competent, there is no inferior or muscular reflux. Any blood removed from the veins by the suction of calf relaxation is, however, replaced from above, so that walking does not relieve the pressure.

(*b*) *Terminal valve competent but perforating veins of the calf incompetent.*—In these cases the superficial veins in this situation are exposed to the powerful inferior or muscular reflux. The amount squirted through is limited, and the effect of this reflux depends on the state of fullness of the veins. Its effect is therefore greatest in those people whose employments involve standing for long periods. During exercise there is a reflux corresponding to muscular contraction, but the superficial veins are partially emptied by the suction of relaxation from contraction. These patients have not the same feeling of weight in the leg as those of group (*a*), and walking relieves the pressure.

(*c*) *Both terminal valve and perforating veins of the leg incompetent.*—Where the whole parietal system has been broken down the vein is constantly filled by the superior reflux. The squirt of muscular contraction therefore acts on a continuously distended vein. The amount withdrawn by relaxation is replaced by descent of blood from above. These cases have a feeling of weight due to the superior reflux, which is at once relieved if the saphenous trunk is either ligated or obliterated.

CONGENITALLY VARICOSE EXTERNAL SAPHENOUS TYPE (CALF-MUSCLE VARICOSIS).

In two out of the ten young subjects certain muscular veins of the calf were not competently valved. These veins, as has been noted, may also be regarded as indirect perforating veins associated with the external saphenous system. The main entrance of the external saphenous vein was competent in the whole series. Here fluid injected into the deep veins did not reach the superficial veins, but flowed readily into certain muscular veins of the calf, and macroscopical examination after dissection of the affected veins showed that the reflux resulted from complete absence of valvular protection. Any or all of the muscular veins in this situation may show this incompetence, but when those affected belong to the gastrocnemial or soleal group (Fig. 7) the corresponding part of the external saphenous system has a very limited barrier of protection from the muscular drive, and superficial varicosis usually develops.

This group is of considerable interest in relation to Verneuil's findings that the intermuscular portion of these veins was varicose while the termination was of normal size. As a result of his observations on varicose subjects he concluded that varicosis commences in the deep veins, particularly those of the calf of the leg. It is also found in the peroneal vein. He attributed the condition to obstruction at the aponeurotic openings through which veins passed, especially the soleal veins. Some of these veins which Verneuil described are undoubtedly connected with the indirect perforating veins of the external saphenous system.

The above experiments place the primary cause of the varicosis commencing in this situation, not with the aponeurotic covering, but in the terminal and parietal valves of the common channel of the indirect perforating and muscular veins (Fig. 3). They do not, however, exclude the possibility of localised parietal valve incompetence apart from terminal valve incompetence in these muscular veins. The two cases in this group were aged 17 and 19 years and were within the varicose age. In both cases varicosis existed in one or other of the parents. In one, deep vein incompetence over a certain length of main vein was also present. In this type, although the direct perforating veins of the internal saphenous and most of the muscular veins of the limb are competent, certain muscular veins of the calf (indirect perforating veins of the external saphenous) are incompetent. An

incompetent indirect perforating vein is usually associated with an incompetence of the muscular vein, and an aching pain in the calf accompanies the condition.

CONGENITALLY VARICOSE DEEP-VEIN TYPE.

It is not possible to give any idea of the frequency of this type, as only six cases were examined and two of these were specially selected as having muscular varicosis. The femoral valve, which, situated beneath Poupart's ligament, dominates the whole venous system of the lower limb, is not infrequently absent. The effect of its absence on an incompetent internal saphenous system has been noted. The effect on the deep circulation is not marked. The deep veins may also be inadequately valved below the knee. In one of these cases showing muscular varicosis, the close valving noted in the posterior tibial venæ comites was interrupted over a considerable area (Fig. 8). Macroscopical examination of the channels after dissection showed almost complete absence of valves in and immediately above the part which the opaque injection method showed to be incompetent. Varicosis of the posterior tibial was recorded by Verneuil, but he specially noted that he never met with a dilatation of the anterior tibial vein. When the deep veins are closely valved, muscular contraction must result in an orderly flow along them, but valvular incompetence throughout a considerable length of the deep vein is likely to progress to serious varicosity, for a long column of blood may be flung back along the distensile vein against the flaps of the first competent valve of the main channel or of the perforating vein. More strain is imposed on these valves, and if the valve of the perforating vein gives way, the rapid development of severe superficial varicosis is likely to follow. Moreover, it is impossible to eliminate the varicose segment from the circulation, and it is difficult to evolve a rational and efficient treatment.

Conclusions.

Though the series is not large enough to be conclusive, these experiments suggest that the inadequacy or absence of the valves—more often those of the perforating but occasionally those of the deep veins, particularly the posterior tibials—is a factor commonly underlying the hereditary tendency to varicosis. This valvular defect is apparently the primary lesion. There is no evidence of weakness of the wall and certainly no sign of dilatation of superficial veins.

The perforating veins include all the channels through which the superficial system drains into the deep circulation. Among them are the terminal portions of the internal and external saphenous vein, which are merely specially developed direct perforating communications. The direct perforating veins of the internal saphenous and the indirect perforating veins of the external saphenous system are all seen to be often affected.

The effect on the superficial system of this congenital incompetence of the perforating veins is not usually apparent until after adolescence. During the period of growth compensation is adequate. This is probably accounted for by the following facts. Prior to adolescence occupations involving prolonged standing are few, the muscles themselves are constantly active and their tone is usually good, the leak back through small veins supported by these muscles is slight, the elasticity of the superficial vein wall is considerable, the diameter of the vein is smaller, and finally, owing to the smaller stature, the hydrostatic pressure in the superficial veins is less. With regard to the indirect perforating veins of the external saphenous: although the muscular veins are incompetently valved at their terminations and in the last part of their course, there is still some valvular protection for the superficial veins, and superficial varices do not arise until this is broken down. If varicosis of the deep veins over a considerable area is present, not only is the condition likely to be more extensive and rapidly progressive, but cure is more difficult.

FIGS. 7. 8.

FIG. 7.—Tendency to varicosis. Calf muscle and external saphenous type. Posterior tibial veins injected with high pressure. Anterior tibial veins filled through communicating veins. No leak into internal saphenous system. Gross incompetence of calf-muscle veins into which drain the indirect perforating veins of the external saphenous. (Lateral view.)

FIG. 8.—Tendency to varicosis. (*a*) Calf muscle and external saphenous type. The veins of the calf muscle are filled from the main deep veins. (*b*) Main deep-vein type. Two perforating veins of internal saphenous injected with high pressure; injection into the upper perforating vein descended the deep veins to the level of the lower; further descent was limited by normal valvular arrangement. Injection into lower cannula did not alter the picture. (Lateral view.)

EXCITING FACTORS.

Given the inherited valvular weakness, the following exciting factors are of importance in connexion with the onset of varicose veins:—

1. Lack of tone or development of supporting muscles. The varicose condition very often comes on during a period of overwork or of recovery from illness.

2. Employments involving standing for long periods of time. The upright position tends to keep the superficial and deep veins full, so that with any contractions of the muscles a reflux through the perforating channels further distends the superficial system. Tight elastic garters may increase the fullness of the veins while in the standing position.

3. Any condition tending to produce weakening of the vein walls. A common example is the onset of varicose veins in pregnancy. This has been attributed to pelvic pressure but, as it comes on before the uterus is bulky enough to cause pressure, some authors consider it to be due to toxins, possibly of placental origin, circulating in the blood. It only affects women of the varicose type. The cases demonstrated above show for the most part complete incompetence of valves. It is probable, however, that many individuals suffer from an incompetence less complete than these subjects. In some the degree is marked

and the toxic effect of a single pregnancy produces a lesion from which the vein never recovers. In others the valves are less incompetent and the degree of recovery after the toxic effect has passed off is sufficient to allow the valves again to act competently. In some of these the valves may finally fail with the circulatory changes that occur at the menopause. Possibly other toxic or trophic conditions produce the same effect as pregnancy, but usually then the exciting cause is not intermittent and varicosis develops progressively. The endocrine disorders which are considered to be of importance in this connexion by Continental writers are regarded rather lightly in this country.

4. Any cause of obstruction to the venous return, such as pelvic tumour, thrombosis of the iliac or femoral vein. The effect of obstruction at openings in aponeurosis cannot be regarded as proved.

5. Any cause of abdominal straining—excessive efforts during defæcation or micturition, caused by constipation, urethral stricture, enlarged prostate.

6. The existence of a heart lesion resulting in venous back-pressure has the same effect as the upright position on full veins.

These exciting factors must all be considered in connexion with the treatment. In addition to blocking a superficial or perforating vein which is hopelessly impaired, it is necessary to keep up the muscular tone by massage and exercise, to avoid long standing, to remove where possible any intermittent or constant cause of back-pressure along the veins, and also to treat any toxic condition likely to impair other comparatively adequate perforating veins.

THE TREATMENT OF ERYSIPELAS WITH VACCINES.

By W. T. Benson, B.Sc. St. And., M.D., F.R.C.P. Edin.,
MEDICAL SUPERINTENDENT, CITY HOSPITAL, EDINBURGH.

THE methods at present available for the treatment of erysipelas may be broadly classified as local applications, internal administration of drugs, and immunisation.

It would serve no useful purpose to enumerate the various medicaments employed as external applications or for internal administration. Most observers with an extensive experience of the disease will agree with Ker [1] "that all the systems of treatment advocated frequently fail to check the advance of the dermatitis, so frequently, indeed, as to justify us doubting whether they exert any favourable influence at all." Roger [2] is not impressed with the specific value of the various antiseptics applied externally, or drugs administered per os.

As pointed out by Meara [3] it is not easy to assess the value of any form of local treatment in a self-limited disease like facial erysipelas, the duration of which is so uncertain. It must be remembered that the natural tendency of the disease is towards cure, and we may reasonably assume that the patient gets better in spite of the remedies employed rather than because of them. A study of the literature from the therapeutic angle makes one wonder whether these points in the natural history of the disease are sufficiently appreciated.

Serum treatment has apparently been successful in the hands of some clinicians, whilst others have not been favourably impressed with the results obtained. Polyvalent antistreptococcal serum gave such disappointing results that its use in this hospital was discontinued several years ago. Recent research in the group of hæmolytic streptococci has led to the production of alleged specific antitoxic sera against scarlet fever, erysipelas, and puerperal infection. The specific scarlet fever antitoxic serum is of proven value. Conflicting reports about the efficacy of the respective antitoxic sera against erysipelas and puerperal infection are met with. These sera have been freely administered to patients in the City Hospital during the past three years. The results obtained will be published at an early date.

In that widely varying results have been reported by different observers, vaccine treatment is no exception to the other remedies employed in the treatment of infection with the *Streptococcus erysipelatis*. Whilst Sill,[4] Fischer,[5] Takaki,[6] Russell,[7] and Boidin and Tierny [8] have apparently obtained satisfactory results in isolated or small groups of cases, Erdman,[9] from his experience of vaccine therapy in 95 cases, concludes that this method of treatment is valueless. Vaccine treatment has also proved a failure in the hands of Boidin and Delafontaine.[10] Ker [11] wrote in 1920: "It is certainly desirable that more work on the therapeutic use of vaccines should be undertaken—a very long series of cases, adequately controlled, will be necessary to establish their efficacy in a disease so variable in its duration and severity."

In this paper I have collected observations on 570 cases of erysipelas, 470 of which were acute attacks, whilst 100 were of a subacute afebrile type.

Method of Investigation.

On admission to hospital, the cases were primarily classified into two groups. One group consisted of typical acute attacks characterised by marked constitutional symptoms. Subacute attacks, in which the systemic disturbance was negligible, formed the second group. To alternate patients in the acute group vaccines were administered, the others acting as controls. We thus have records of 235 acute cases treated with vaccines, and an equal number of patients suffering from acute attacks who received purely symptomatic treatment.

TABLE I.—*Original Site of Infection.*

Series.		Face, ears, or scalp.	Trunk	Genitals.	Arms.	Legs.	Tot
Vaccine		207	10	4	0	14	23
Non-vaccine	Acute ..	203	6	4	6	16	23
	Subacute	94	0	0	1	5	10
Totals		504	16	8	7	35	57

The original site of the inflammatory process in the various groups of cases is shown in Table I.

As might be expected facial cases preponderate, amounting to 88 per cent. of the vaccine-treated series and 86 per cent. of the control group.

Treatment.

The therapeutic measures employed for the relief of delirium, insomnia, and high temperature were the same in all cases. The following local applications were tried: (*a*) lint kept constantly moist with a cold saturated aqueous solution of magnesium sulphate to which 10 to 20 per cent. of glycerin had been added; (*b*) collosol iodine, and (*c*) a 5 per cent. aqueous solution of brilliant green (as recommended by Adams [12]). The latter two preparations were painted on and beyond the inflamed area morning and evening. The solution applied to the inflamed area in various groups of cases is shown in Table II.

TABLE II.—*Local Applications.*

—	Acute series.		Sub-acute series.	Total.
	Vaccine cases.	Non-vaccine cases.		
Magnesium sulphate ..	156	161	80	397
Collosol iodine ..	51	44	0	95
Brilliant green ..	28	30	20	78
Totals	235	235	100	570

It will be seen from Table II. that suitable control cases were obtained in the acute non-vaccine series for each group in the vaccine series. We thus hoped to assess, and eliminate if possible, any variation that might arise from the alteration of the local treatment.

VACCINES.

The vaccines administered may be broadly grouped into "stock" and "hospital." The former group included commercial preparations containing *S. erysipelatis*, or *S. pyogenes*, polyvalent streptococcal vaccine, and a combined streptococcal and staphylococcal vaccine. The "hospital" vaccine was prepared from strains of *S. erysipelatis* isolated from the inflammatory area in six acute cases of the disease. An autogenous vaccine was administered to five patients. The relatively brief duration of the disease in the vast majority of patients proves a stumbling-block to the extensive employment of autogenous preparations.

Whilst the vaccine was injected subcutaneously in all cases, the total dosage and the interval between injections varied considerably. One hundred and thirty-six patients received a course of six injections administered either daily, or at two-, three-, or four-day intervals. Fifty cases received either four or five injections of vaccine. To the remaining 49 individuals from one to a maximum of ten doses were administered. The actual number of cocci injected varied according to the severity of the infection and the age of the patient, ranging from a primary dose of 250,000 organisms in an infant 3 weeks old to a maximum primary injection of 10 million streptococci. The average course for an adult ranged from an initial dose of 5 million streptococci to a final injection of 200 million organisms. The usual interval between injections was three days. A course of daily injections ranging from 1 to 20 million cocci was administered to a small group of sharp cases. The dosage of mixed vaccine rose from an initial injection of 10 million streptococci combined with 500 million staphylococci to a maximum dose of 100 million streptococci plus 5000 million staphylococci.

Result of Vaccine Treatment.

In endeavouring to estimate the therapeutic value of the vaccine employed, attention was paid to (*a*) the duration of pyrexia, (*b*) the extent of spread of the inflammatory lesion, (*c*) the incidence of complications, (*d*) the occurrence of relapses and second attacks, and (*e*) the mortality-rate. The following criteria were adopted:—

Day of Crisis.—The day on which the morning or evening temperature was first normal and did not subsequently rise, except when due to an obvious complication, was considered as the day of crisis.

Day of Cessation of Activity.—Day on which the local inflammation had entirely subsided.

Wandering Type.—Implies invasion of neck or trunk from a primary focus on either face or limb, or of limb or face from an original focus on the trunk.

The age and sex of the patient, and the day of disease on which the patient was first admitted to hospital, are of importance, when the value of any method of treatment for erysipelas has to be assessed. Whilst the gravity of erysipelas at the extremes of life is common knowledge, the fact that the death-rate tends to be higher in males at all ages than in females is perhaps not so widely appreciated. The age and sex of vaccine-treated and control cases are noted in Table III.

TABLE III.—*Age and Sex of Acute Cases.*

Series.	Sex.	Under 1 yr.	Age-period in years.										Totals.
			1–4	5–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	80–89	
Vaccine	M	6	8	5	11	14	15	23	16	10	3	1	112 } 235
	F	6	4	3	18	17	15	24	18	14	4	0	123 }
Non-vaccine	M	7	6	1	6	4	13	22	18	13	4	0	94 } 235
	F	3	8	2	26	28	16	22	21	10	4	1	141 }
Totals ..		22	26	11	61	63	59	91	73	47	15	2	470

The number of patients under 5 years and above 60 years of age was 56 in both groups. Unfortunately, the sex incidence is not so strictly comparable. Males form 47·7 per cent. of the vaccine-treated group as against 40 per cent. of the control group.

Table IV. gives us information regarding the day of disease on admission to hospital in the two groups of cases.

TABLE IV.—*Day of Disease on Admission to Hospital.*

Series.	Day of disease.													Totals.
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	
Vaccine. ..	15	55	64	35	38	11	3	8	1	1	3	0	1	0	235
Non-vaccine..	13	61	57	50	24	11	8	6	0	0	2	2	0	1	235
Totals ..	28	116	121	85	62	22	11	14	1	1	5	2	1	1	470

The average duration of illness prior to admission to hospital in the 235 cases treated with vaccine was 2·67 days. In the 235 non-vaccine treated (control) cases it was 2·64 days.

The two groups are strictly comparable as far as age distribution and duration of disease prior to hospital treatment are concerned. The sex distribution unfortunately varies to a slight degree.

DURATION OF PYREXIA.

In facial erysipelas the temperature tends to fall more or less abruptly with the cessation of the inflammatory process. In the absence of complications, the period of pyrexia may be regarded as a fair estimate of the duration of the illness. Table V. shows the duration of pyrexia subsequent to admission to hospital in the two groups of cases.

TABLE V.—*Duration of Pyrexia Subsequent to Admission to Hospital.*

Series.	Days.														Totals.
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	
Vaccine.. ..	36	38	34	34	27	11	16	7	8	8	5	1	2	8	235
Non-vaccine..	18	33	40	34	38	20	9	11	4	7	1	2	4	14	235
Totals ..	54	71	74	68	65	31	25	18	12	15	6	3	6	22	470

The average duration of pyrexia subsequent to admission to the wards in 235 vaccine-treated cases was 4·97 days. When we add this figure to the average duration of illness before admission—namely, 2·67 days—we arrive at an average total duration of disease in the vaccine-treated series of 7·64 days. In the 235 control cases the average duration of pyrexia subsequent to admission to hospital was 5·41 days. When we add this to 2·64 days, the average duration of illness prior to admission to the wards, we find the average total duration of disease in the control group amounted to 8·05 days.

EXTENT OF SPREAD OF INFLAMMATORY PROCESS.

Should vaccine therapy be efficacious, one would expect that the tendency of the inflammation to "wander" would be much curtailed. The incidence of the wandering type of erysipelas in the two groups of cases is shown in Table VI.

TABLE VI.—*Incidence of "Wandering" Type.*

Cases.	Extent of spread.			Totals and per cent.
	Face to neck.	Face to trunk.	Trunk to limbs or vice versa	
In 235 vaccine	17	18	9	44(18·71)
In 235 non-vaccine ..	11	33	9	53(22·5)

Whilst the figures are in favour of the vaccine-treated group, it is to be noted that extensive spread of the inflammatory lesion occurred in 44 cases in spite of vaccine administration.

INCIDENCE OF COMPLICATIONS.

The various complications met with in the two groups are given in Table VII.

TABLE VII.—*Complications.*

—	Abscesses and cellulitis.	Broncho-pneumonia.	Nephritis.	Pyæmia.	Arthritis.	Totals.
Vaccine series (235) ..	10	2	2	1	0	15
Non-vaccine series (235)	10	4	2	1	1	18

It is disappointing to note that the development of abscesses and cellulitis was apparently unaffected by the administration of vaccine. The lower incidence of broncho-pneumonia in the vaccine-treated series is interesting, although, owing to the relative infrequency of this complication, not entirely convincing.

INCIDENCE OF RELAPSES AND RECURRENCES.

A recurrence may be defined as a repetition of the disease after an interval of months or years. As a purely arbitrary standard, we shall consider a reappearance of the disease within three months of the previous attack as a relapse. Where a period of more than three months has intervened, then a flare up of the erysipelatous process will be regarded as a recurrence. Sixteen cases in each group suffered from a relapse whilst still in hospital. In the vaccine-treated group another four patients were readmitted to hospital within three months of the previous attack and will thus be regarded as suffering from relapses. The percentage of relapses in the vaccine-treated series amounted to 8·5, as against 6·8 in the control series.

No fewer than ten patients who had received a course of vaccine during one attack of erysipelas were readmitted with, in most cases, an equally sharp second attack of the disease from four to 29 months later. Details of two of these cases, chosen at random, are appended:—

CASE 1.—Mrs. A., aged 35. Original attack December, 1921. Facial. Stock streptococcal vaccine. Five doses at three-day intervals ranging from 20 million to 400 million cocci. Second attack March, 1923. Facial. Stock streptococcal vaccine. Six daily doses, 5 to 15 million cocci. Relapse occurred fourteenth day in hospital.

CASE 2.—Mrs. B., aged 58. Original attack February, 1922. Facial. Six doses mixed streptococcal and staphylococcal stock vaccine administered every third day, ranging from 10 million streptococci plus 500 million staphylococci to 200 million streptococci plus 1000 million staphylococci. Second attack March, 1923. Facial. Temperature ten days.

MORTALITY.

In Table VIII. we have the deaths which occurred in the various age-groups.

TABLE VIII.—*Deaths.*

Series.	Result.	Under 1 year.	Age-period in years.								Totals
			1–4	5–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	80–	
Vaccine	R	6	11	8	29	31	27	44	32	21	5	0	214
	D	6	1	0	0	0	3	3	2	3	2	1	21
Non-vaccine	R	6	12	3	30	32	28	40	34	19	6	1	211
	D	4	2	0	2	0	1	4	5	4	2	0	24

R = Recovered; D = Died.

The death-rate in the vaccine-treated series was 8·94 per cent. as compared with a rate of 10·21 per cent. in the control group. The slight variation in favour of the vaccine series need not, in my opinion, be regarded seriously. It is only fair to remember, however, that the preponderance of males in the vaccine-treated patients would have led one to expect a rather higher mortality in that group than in the control series.

LOCAL TREATMENT.

Without going into detail, it may be stated that a critical analysis of the various local applications led us to the conclusion that in no case did they limit the spread or materially diminish the activity of the inflammatory process. The patients certainly testified to the alleviation of subjective symptoms which followed the application of all three lotions. I still favour as a local application a cold saturated aqueous

solution of magnesium sulphate to which 10 to 20 per cent. of glycerin has been added.

Conclusions.

The study of 235 carefully controlled acute cases of erysipelas has led to the following conclusions. The administration of stock or autogenous streptococcal vaccines, or mixed staphylococcal and streptococcal vaccines, in erysipelas does not (*a*) shorten the duration of the attack, (*b*) prevent extensive spread of the inflammatory process, (*c*) lessen the incidence of common complications such as abscesses and cellulitis, (*d*) diminish the occurrence of relapses, (*e*) prevent recurrences, or (*f*) have any appreciable effect in diminishing the mortality from the disease.

SULFOSIN THERAPY.

By T. D. Power, M.D. Dub., M.R.C.P. Lond., D.P.H., D.P.M.,

DEPUTY MEDICAL SUPERINTENDENT, BRENTWOOD MENTAL HOSPITAL.

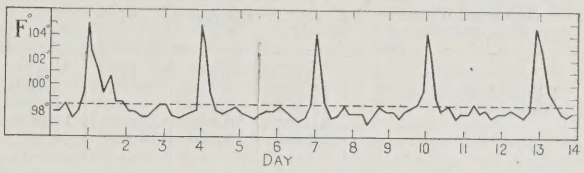
In a paper published at the end of last year Schroeder[1] advocated the use of a preparation of sulphur in oil, known as Sulfosin, in the treatment of general paralysis and certain other nervous and mental disorders. Since that date several other publications dealing with the same subject have appeared, among which may be mentioned those of Harris,[2] Shilvock,[3] and Patterson and Switzer.[4]

For a period of about eight months I have employed injections of sulfosin in the treatment of 14 cases of certified insanity, the majority being general paralysis of the insane. Unfortunately the type of general paralytic who finds his way into a mental hospital is more often than not in an advanced state of cerebral dissolution. His nervous tissue has already undergone a certain amount of irreparable damage and the most that can be achieved by any form of therapy is the arrest of the processes of destruction and the limitation of dementia. Exceptionally, patients are admitted at an early stage of the disease, and it is now generally conceded that very often these may be restored to complete normality by artificially induced malaria. Where, however, gross neuronic damage already exists, one can only appraise the therapeutic worth of any remedy by observing the treated cases over a number of years and noting whether or not the disease has been arrested. For this reason no attempt will be made here to comment on the curative value of sulfosin in the treatment of the complaint for which it was first advocated, but rather to indicate some points of interest about the therapy itself.

Pyrexia.

Regarded purely as a pyrexia-producing agent, sulfosin is, in my experience, far superior to any other substance which has been suggested for this purpose. If Schroeder's directions[1] are carefully followed, an intramuscular injection of this preparation will in the vast majority of instances produce a high temperature within the ensuing 24 hours, and this will almost invariably have completely subsided within 72 hours. By altering the dose the height of the temperature can be regulated with singular accuracy, and usually it is quite unnecessary to employ maximum doses in order to produce an intermittent pyrexia of 104° F.

CHART 1.

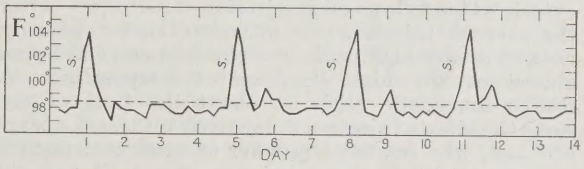


Pyrexia of induced quartan malaria.

A temperature chart closely resembling that of malaria can be obtained without any difficulty, as the accompanying records of actual cases clearly demonstrate.

Chart 1 is that of a case of a general paralytic undergoing treatment by induced quartan malaria and needs no special explanation. Chart 2 is taken from another case of general paralysis who was undergoing sulfosin treatment. In the malaria chart rises of temperature to between 104° and 105° F. are recorded regularly every 72 hours, whereas in the other chart similar pyrexial bouts are produced at any desired interval by an injection of 4·5 c.cm. of sulfosin at 11.30 A.M. on the previous day. As compared with the pyrexia associated with a malarial rigor, the temperature produced by sulfosin takes a little longer to subside, and there is usually a slight secondary rise on the second night following the injection. This secondary elevation is very characteristic of fever induced by sulfosin, but it should be noted that in the case illustrated the temperature had always entirely subsided within 48 hours.

CHART 2.



Pyrexia induced by sulfosin. Injection of 4·5 c.cm. sulfosin at S.

I usually confine myself to eight or ten injections in one course of treatment, but every case has to be judged on its merits as in malaria therapy. A few weeks are allowed to elapse before a second course of injections is given, and this may be followed later by a third course. No marked toleration appears to be established; similar rises of temperature can be obtained in the third course with very much the same doses as were employed at the commencement of the treatment.

Leucocytosis.

One of the most characteristic effects of sulfosin is the very considerable leucocytosis. This reaches its maximum 24 hours after each injection, and in a number of cases the white count has not returned to normal in 48 hours. The accompanying table shows the leucocytic changes which occurred in the blood of four of my cases. The counts were performed half an hour before each injection, and again at intervals of 3, 24, and 48 hours after it, care being taken to avoid the possibility of a post-prandial leucocytosis.

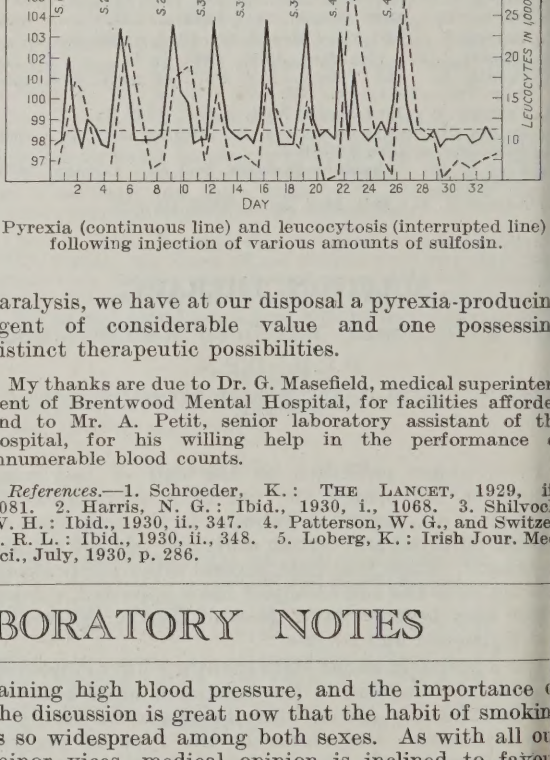
Time before and after injection.	Leucocyte count.			
	(1)	(2)	(3)	(4)
½ hour before	10,400	8,540	7,840	5,280
3 hours after	19,200	8,400	8,800	4,800
24 ,, ,, ...	31,200	16,000	28,000	15,900
48 ,, ,, ...	14,200	8,700	16,800	8,400

A differential count at the height of the leucocytosis showed in the majority of instances a marked relative increase of neutrophil polymorphonuclear cells, so that it is very unlikely that this phenomenon is due to a mere change in blood volume. It indicates rather that there is a general stimulation of the blood-forming organs. In certain cases a white blood count was done every morning at a fixed hour during a course of eight sulfosin injections. The results were very interesting and an attempt has been made to record graphically one such series of counts in Chart 3.

The unbroken line represents the maximum morning and evening temperatures. The broken line indicates the course of the daily white count, which was taken at 9.45 A.M. The amount of each dose of sulfosin, which was always given about 11.30 A.M., is also recorded. The chart shows faithfully the leucocytosis which follows each injection of sulfosin. After the seventh injection the leucocyte curve suddenly rises to a very high peak, and this is succeeded by an almost equally high elevation of temperature. A similar leucocytic crisis at about the time of the seventh sulfosin injection is reported by Karl Loberg[5] of Lund, who treated a number of cases of dementia præcox by this method. My impression is that such extreme leucocytic reactions should be regarded as Nature's distress signals and are indications that the injections should be temporarily discontinued. If Chart 3 be further examined it will be observed that there is no constant ratio between the extent of the leucocytosis and the height to which the temperature rises; nevertheless some relationship definitely exists, because in the only one of my 14 cases in which pyrexial bouts above 103° F. could not be obtained, the leucocytic responses were similarly poor, except after the sixth and seventh injections, when they were very considerable.

These effects of sulfosin on the white blood cells are of absorbing interest and are worthy of much more detailed examination. Whether or not this substance ultimately proves of use in the treatment of genera

CHART 3.



Pyrexia (continuous line) and leucocytosis (interrupted line) following injection of various amounts of sulfosin.

paralysis, we have at our disposal a pyrexia-producin agent of considerable value and one possessin distinct therapeutic possibilities.

My thanks are due to Dr. G. Masefield, medical superinten dent of Brentwood Mental Hospital, for facilities afforde and to Mr. A. Petit, senior laboratory assistant of th hospital, for his willing help in the performance innumerable blood counts.

CLINICAL AND LABORATORY NOTES

TOBACCO-SMOKING AND HIGH BLOOD PRESSURE.

BY H. H. SANGUINETTI, M.D. OXF.

"HIGH pressure is an attempt of the organism to maintain the equilibrium of its circulation." This quotation from Clifford Allbutt is placed at the head of the chapter on "the causation and significance of high arterial pressure" in Halls Dally's treatise on "high blood pressure." The conclusion to be drawn from such a statement is that it is worse than useless to lower the blood pressure in these cases unless one can at the same time remove the cause. Halls Dally proceeds, however, to point out that "the primary cause or causes of pathologically high arterial pressures are not definitely established," finally tabulating eight possible causes of the condition, among these being toxins.

There has been some discussion on the rôle played by the toxin of tobacco-smoke in producing or maintaining high blood pressure, and the importance the discussion is great now that the habit of smokin is so widespread among both sexes. As with all ou minor vices, medical opinion is inclined to favou moderate indulgence in the habit, probably a sociall wise but hardly a scientific attitude. As a contributio to the study of this question of the influence smoking on blood pressure the following case is interest:—

The patient, a man then aged 54, consulted me September, 1927, about a pain of moderate degree in t right loin, probably rheumatic. He had suffered fro nephritis while in France in 1916, and there was so permanent damage to the kidney, the urine constant containing a trace of albumin. He was micturating fr quently, and an estimation of his blood pressure gave systolic reading of 235 mm. Hg, with a diastolic pressure 135 mm. The heart was considerably enlarged, with t apex-beat in the sixth space one inch external to the nipp line. The heart sounds were normal, with the excepti of some accentuation of the second sound at the base. T radial arteries did not appear to be affected with arter sclerosis. The Wassermann reaction was negative.

The history and the clinical findings suggested that t primary condition was chronic nephritis with seconda arterio-sclerotic changes. The patient did not take alcoh

but smoked about 17 cigarettes a day. Although there were no obvious disturbances of health, except a feeling of lassitude, such a high blood pressure in a nephritic subject could not but be regarded as serious. Tests of renal function were satisfactory, showing blood-urea 0·038 per cent., urea concentration 2·9 per cent., and range of urea concentration (Calvert's test) 2·2 per cent. to 1·45 per cent. The last test indicated some impairment of water excretion, but there was no other evidence of water retention.

For three years the patient ran through the gamut of treatments: iodine, thyroid extract, a vaccine from extracted teeth, high-frequency current, venesection, a course of treatment at Harrogate, and the oral administration of sodium thiosulphate. Venesection (very temporarily) and sodium thiosulphate reduced both systolic and diastolic pressures considerably, but the latter made the patient feel so poorly that he discontinued it. In May of this year the blood pressure was 230/130; the general condition was much the same, with a possible slight impairment of renal function, the urea concentration (which had been 3·7 per cent. in 1928) being now only 2·6 per cent.

Without hope of dramatic change I urged the cessation of tobacco-smoking, a measure I had unsuccessfully urged when I was first consulted. The patient now accepted my advice, and by a gradual process had ceased smoking at the end of a fortnight. Coincident with the reduction of smoking the blood pressure fell to 182/95, while cessation of smoking was followed by a further fall to 175/85.

It cannot be said that in consequence of the reduction the patient felt better, but he had not the unpleasant sensations accompanying the fall produced by the exhibition of sodium thiosulphate, and the urea concentration of 3·6 per cent. indicates improvement of the renal function. Time is required for the organism to adjust itself to so considerable a fall in blood pressure. However, the prognosis appeared distinctly more hopeful, when the patient resumed his cigarettes, apparently not considering the lowering of the blood pressure without a more immediate improved sense of well-being sufficient compensation for the great deprivation of smoking. The blood pressure responded by rising, and when the habit had been fully resumed it had returned again to its previous high level. As further evidence of the effect of smoking on this patient I am inclined to welcome his fall from grace, but I fear that the continued high blood pressure may soon have produced irremediable changes in the circulatory system and kidneys.

London.

A CASE OF UNDULANT FEVER.

By Denton Guest, M.D. Sheff.,
PATHOLOGIST TO THE HUDDERSFIELD ROYAL INFIRMARY;
AND
. G. Moore, M.D. Vict., M.R.C.P. Lond., D.P.H.,
MEDICAL OFFICER OF HEALTH, HUDDERSFIELD.

On August 18th, 1929, a man was admitted to the Huddersfield Royal Infirmary complaining of attacks of shivering, intense sensations of bodily heat, followed immediately by very profuse sweating. He had suffered from this condition for three weeks before his admission to hospital.

On July 20th, 1929, he went to Colwyn Bay for his holidays and remained there until July 31st. During this period he had one or two shivering attacks, after which he perspired very freely, and felt generally out of sorts. He returned to work on August 1st, and on August 4th he felt very ill, had violent shivering attacks, and could not keep warm, even when near a hot fire. His doctor was called in and noted that he had a high temperature, and also that he complained of aches in his legs, but was unable to find any definite muscular pains or any evidence of gastro-intestinal disturbance. Between the rigors the man appeared to be in quite good health, but on August 18th the doctor decided to get him to hospital for investigation, and he was accordingly admitted on that day.

Clinical examination in hospital revealed nothing of note; the spleen was not enlarged, but his chart soon showed that there was a rise of temperature each afternoon, at almost the same time each day, to the region of 100° to 102° F.; this state of affairs continued for four days. In each case the rise of temperature was accompanied by a typical rigor and was succeeded by the most profuse sweating.

The question of malaria arose, but blood films failed to show any parasite, and the only occasions on which the patient had been out of England were in 1911 to Jersey, and on several occasions since to Ireland. Blood examinations revealed a leucopenia (5000 leucocytes per c.mm., of which 41 per cent. were lymphocytes). Blood cultures were collected on three occasions but remained sterile, even after ten days' incubation at 37°C. The Widal reaction was negative to *B. typhosus* and *B. paratyphosus* A and B. Examination of the urine and fæces proved negative.

At this stage a tentative diagnosis of undulant fever was made, and was confirmed by testing for agglutinating power the serum of the patient with the standardised agglutinable suspensions of *B. melitensis* and *B. abortus* supplied by the Standards Laboratory, Oxford. The patient's serum caused agglutination to a titre of 1 in 500.

By this time his condition had markedly improved; the rigors, which had occurred every day at first, became less frequent, and at the end of three weeks had completely ceased, no further rises of temperature being noted.

As soon as a diagnosis of undulant fever was confirmed it was deemed prudent to notify the medical officer of health for Huddersfield, in order that he might trace the avenues of infection. This was a matter of considerable difficulty, in view of the fact that the patient had begun to be ill in Colwyn Bay, and our thanks are due to Dr. W. McKendrick, medical officer of health for Colwyn, for his help in inquiring into the question of any similar cases, and of any cases of abortion in cattle in his area. He found no evidence of any such cases.

One of us (S. G. M.) instituted inquiries at all farms in the Huddersfield area from which milk had been supplied to the patient, but he was assured that no cases of cattle abortion had occurred in their animals, and he also noted that these farms had been recently inspected by the veterinary surgeon. Samples of milk were examined bacteriologically by the public health authority, with negative results, and samples, together with controls, were tested by one of us (D. G.) for agglutination of the suspensions of *B. melitensis* and *B. abortus*, again with negative results.

No other cases of a similar nature have been reported in the Huddersfield area, and this is evidently a sporadic case of undulant fever. We wish to emphasise the importance of coöperation, in all such cases, between the clinician and the public health authorities, with a view to tracing the source of infection, even though in our case we can only produce negative results. It would also seem worth while in the investigation of pyrexia of unknown origin to make the test for agglutination of *B. abortus* a routine procedure, as these cases appear to be on the increase in this country.

Our thanks are due to Dr. Jane Miller, honorary physician to the Royal Infirmary, Huddersfield, for permission to carry out these investigations.

Manchester Epileptic Colony Extension.—It has been decided to enlarge three of the houses of the David Lewis Epileptic Colony. Last year the average number of colonists was 376, and Dr. Alan McDougall points out in his annual report that these were patients who had failed to respond to medical treatment at home. The successes of the colony he attributes mainly to the general atmosphere and mode of life.

Swansea General and Eye Hospital.—In the report for the year 1929 attention is called to the difficulties of accommodation and the long waiting-list, which at the end of the year numbered 442. Accidents and emergencies represent approximately 50 per cent. of the total admissions; thus only half the number of beds are available for the normal numbers applying for hospital service. The average daily number of in-patients was 266·41, and the average stay 21·21 days. The average cost per bed occupied was £145 19*s.* 2*d.* The 28,891 out-patients cost 7*s.* 1½*d.* each. Employees' contributions totalled £24,816, an increase of £955 over the previous year.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

AT a meeting of this Section on Dec. 3rd, the President, Mr. C. H. FAGGE, being in the chair, a discussion on

Surgery in Diabetes

was opened by Prof. G. E. GASK. The subject fell, he thought, conveniently under headings—e.g., what should be done (*a*) when glycosuria is discovered in a patient for whom an operation of convenience (hernia, removal of appendix in the quiescent period) is proposed; (*b*) in a patient requiring a life-saving operation, such as intestinal obstruction or acute appendicitis; (*c*) in a case of gangrene associated with diabetes; (*d*) in pyogenic infection such as carbuncle associated with diabetes. In 1898 Treves wrote: "Diabetes offers a serious bar to any kind of operation for injuries involving open wounds; hæmorrhage or damage to vessels are exceedingly grave in the subjects of this disease." If a patient at that time came to St. Bart.'s and was discovered to have diabetes, operation was avoided. This was in pre-insulin days. The introduction of insulin had greatly modified surgical practice; operations previously undreamed of in diabetic subjects were now carried out with comparative safety.

Dealing with heading (*a*), he would say that, given proper treatment and a due quantity of insulin, there was no bar to operation, for there would be but little more risk than in the ordinary patient. Under heading (*b*) he would say that the life-saving operation should not be postponed. The surgeon should inject a proper amount of insulin and give an appropriate course of antidiabetic treatment. Under heading (*c*), he was speaking of the type of patient who had arterio-sclerosis plus diabetes in addition, with commencing gangrene of a toe. Here he did not feel justified in speaking dogmatically, as he did not feel quite sure. In pre-insulin days he would have advised amputation of the limb, high up where collateral circulation was best. Now a more conservative treatment could be carried out with safety. By the proper use of insulin, associated with warmth and light treatment, much could be done to prevent the spread of the gangrene and its change from the dry to the wet form. Under heading (*d*) he felt that more than in any other kind of case, insulin should be given, and given early, steps being taken to lessen the severity of the pyogenic infection, for suppuration had a serious effect on the diabetic process.

Local anæsthesia was to be preferred, said Prof. Gask, in the great majority of cases. But if local anæsthetics were not available or there was some good reason against their use, a general anæsthetic must be given. Operation had to be done quickly, and the choice of the anæsthetic must be subservient to that. If gas-and-oxygen was not sufficient, it should be supplemented by ether; chloroform was to be avoided.

MEDICAL ASPECT.

Dr. GEORGE GRAHAM said that under Prof. Gask's first heading the prime necessity was to make a diagnosis, for not every one who had dextrose in the urine was diabetic. If diabetes was diagnosed and operation was required, there should be a proper preparation of the patient by insulin and dieting. That should always be possible, unless the diabetes was very severe, in four to seven days. Every large hospital should by now, he thought, have an expert dietitian, with proper kitchen, so as to ensure a patient having the food he was supposed to have. Three hours prior to operation such patients should be given a definite dose of sugar, and 15 or 20 units of insulin; half an hour before operation was due to commence another dose of sugar should be given, to ensure that the patient had enough glycogen in the liver in case it was necessary to give ether as a general anæsthetic. In acute cases it was impossible to delay the operation while the patient was being prepared in the way mentioned; but if time allowed, a blood-sugar estimation should be done, 50 g. of dextrose being given by the mouth. Some people with severe diabetes did not have a high blood-sugar; a large dose of insulin did them harm. He gave insulin before the dextrose. If the patient was vomiting sugar should be given intravenously in a pint of saline. Saline was useful in a vomiting patient as it gave him back some of the salts he had vomited.

There was, he thought, no such condition as diabetic gangrene in the sense that diabetes predisposed to gangrene; these people had gangrene because they had bad arteries; possibly a badly chosen diet, with much fat, had helped to produce the arterial disease. But diabetes certainly made the gangrene worse. Once diagnosed the sooner pathogenic infections were dealt with the better, because all septic conditions adversely affected the patient's sugar tolerance. The longer such patients had the infection and were without due quantities of insulin, the worse would the diabetic condition become; any disease would have the same effect. A woman of 77 with carcinoma of the breast, for which radium was inserted, required double the amount of insulin during the time the radium was in situ in order to keep the sugar curve right. On the removal of the radium a return to the former insulin dose was possible. In such conditions as severe carbuncles insulin was very valuable; the same was true in many states of deterioration of tissue, and in certain patients who had not got frank diabetes.

DISCUSSION.

Dr. R. D. LAWRENCE wished, for practical purposes, to make a clear distinction between ordinary surgical procedures in diabetics, and surgery in conditions produced entirely or partially by diabetes. In the first group he considered that the surgeon need have no special considerations or special responsibilities. Patients in the second group required special thought. He showed a table of 163 cases of diabetes which had been operated upon, with 13 deaths. Most of the patients who died were elderly and were, he said, carried off mainly by complications to which anyone of similar age would be liable. In all these operations the thing to fear was the onset of acidosis. A glycosuria lasting only a few days needed little consideration so long as the sugar was controlled. It was impossible to lay down a standard of treatment for every case; each patient must be separately dealt with. Often there was a changing degree of sepsis in these conditions, and as the sepsis became better the diabetes grew less.

Chloroform was the worst anæsthetic because it had the greatest toxic action on the liver; even under the best conditions of treatment the liver of the diabetic never had as much glycogen as the normal

ne; a liver deficient in glycogen was liable to suffer arenchymatous damage from chloroform. So long s no local sepsis was present, he thought local næsthesia was best. For operations on the lower mbs, spinal anæsthesia was ideal. Avertin was rgely used in American clinics for diabetic cases; e had tried it in two cases and had been very tisfied. It was important to avoid vomiting fter operation; if the patient vomited and was not iven carbohydrate and insulin he drifted into cidosis, and the vomiting became worse. After peration it was necessary to watch the patient losely, and, if necessary, to vary the treatment from our to hour, certainly from day to day.

If the circulation was good, a case could be treated n the usual surgical principles, the best guide to the ate of the circulation being the degree of pulsation in ie dorsalis pedis artery. Sometimes there was present combination of calcification and obliterative ndarteritis. The skiagram was apt to mislead ecause apparent calcification did not necessarily ean that the leg must be amputated high up. 1 the presence of a rapidly spreading sepsis and mphangitis there was no possibility of saving the mb; one could only strive to save life. In cases of hat might be called the diabetic acute abdomen, was difficult to decide what to do; it might be 1 acute appendix, a perforated gastric ulcer, or other bdominal catastrophe. If the temperature was ised, that was in favour of the pain and symptoms ot being entirely due to the diabetic condition. there was reason to suspect acute disease, like ppendicitis, it was better to operate, even at the sk of being proved wrong.

Mr. CYRIL NITCH said that to deal successfully ith cases of diabetes required close coöperation etween surgeon, physician, and biochemist. In man of 80 with prostatism, he had seen extreme rvousness produce a reduction of Fehling's solution; hen the nervousness had passed the urine was normal ain. Insulin must never be given in a haphazard ay; it must always be controlled. A minor opera- on might be dangerous, whereas a major operation ight restore the balance. When the case was not gent, stabilisation could be produced by diet alone, only a small amount of insulin might be needed fore (and possibly after) operation. In emaciated d septic cases insulin must be given with caution, only a small amount of it might cause hypo- ycæmia. In the presence of severe acidosis which ght develop two days after ether anæsthesia, ucose should be given intravenously. Fluid in antity should be given, because comatose patients re rapidly dehydrated. He agreed that spinal æsthesia was best for operations below the umbilicus. 1 objectionable sequel of gas-and-oxygen was anosis; unless administered by an expert it was t suitable for prolonged operations. He recognised o types of gangrene: (1) due to arterio-sclerosis— ., senile gangrene in a diabetic; (2) due to infection gravated by diabetes but not always complicated a defective circulation. Non-operative measures re applicable to superficial gangrenous patches or ers; these included systematised exercises— o minutes elevation of the limb, followed by three nutes depression—and the use of artificial sunlight. r sepsis and spreading gangrene high amputation uld be done without delay.

Dr. OTTO LEYTON said it was not infrequent for angrenous patch to heal even when there was no preciable pulse at the ankle. At the London spital he treated his cases of gangrene with hot ine, and with warmth for long periods. He could confirm the good results obtained by H. N. Mukhirjee, from the use in these cases of phospho-tungstate of insulin.[1] It seemed as if, in the future, it might be possible to control diabetes mellitus by the administration of this insulin preparation by the mouth though it was true that about six times the usual dose was needed.

Dr. P. W. CAMMIDGE spoke of the high proportion of diabetics who had septic feet; when treated with insulin, local cleansing, and careful dieting even apparently hopeless cases recovered. He spoke approvingly of avertin as an anæsthetic. To cases of diabetes requiring operation he gave insulin and glucose before the operation, and an injection of glucose in a considerable quantity of fluid immediately after. The whole of the treatment should be controlled by blood-sugar analyses.

Mr. J. B. HUNTER spoke of the control of severe cellulitis in young patients by means of insulin; the process was in this way kept local, and the abscess could subsequently be evacuated. Diabetics often developed a sore on an unclean foot which was not gangrenous. These cases should be sat up in bed to check the tendency to spread into the tendon sheaths.

Dr. E. SKIPPER also emphasised the importance of the care of the feet, especially in the middle-aged. At the London Hospital it was the practice to watch these cases as long as possible, giving them local treatment such as saline baths, covering with a layer of gauze and exposure to the sun.

SECTION OF OTOLOGY.

AT a meeting of this Section, held on Dec. 5th, with Mr. ALEXANDER TWEEDIE, the President, in the chair, a discussion on

Intracranial Complications of Otitic Origin

was opened by Dr. GEORGE RIDDOCH, who dealt with neurological examination and the indications which should lead the clinician to suspect the spread of infection inwards and the presence of retained pus within the skull. His contribution, he said, might be regarded as complemental to a paper on the diagnosis and localisation of cerebral abscess, read by Dr. C. P. Symonds to the Section three years earlier.[2] What symptoms and signs should, Dr. Riddoch asked, lead to the suspicion that intracranial symptoms might develop in cases of ear infection? He thought it best to limit the discussion to cases in which adequate drainage had been established, as by spontaneous rupture of the drum, or by paracentesis. If in acute ear disease, in spite of good drainage, the patient continued to feel ill and had no appetite, had also headache and increased pulse-rate, spread of the infection was probable. After a few days the symptoms might subside, and not recur, owing either to the mildness of the infection or to the patient's natural powers of resistance. Yet the passage of the acute stage did not necessarily mean that danger was past. Instead of subsiding, the symptoms might merge into those of acute intracranial complications, such as lateral sinus thrombosis, extradural abscess, meningitis, and encephalitis. The occurrence of these symptoms should demand periodic examination for some months.

Acute complications.—Lateral sinus thrombosis was indicated by a swinging temperature, shivering or rigors, and tenderness over the jugular. Additional evidence was sometimes supplied by Queckenstedt's test. Extradural abscess was notoriously difficult

[1] See THE LANCET, Sept. 27th, p. 707.
[2] THE LANCET, 1927, i., 392.

to diagnose, especially in cases of acute otitis media before drainage had been established, as the symptoms were overshadowed by the aural condition. In regard to mastoiditis, Dr. Symonds doubted whether uncomplicated mastoid disease was associated with spontaneous complaint of headache, though tenderness to pressure was an almost constant and a very important sign. If that were true it was a great clinical help. Dealing next with meningitis, Dr. Riddoch considered that the qualification "serous" should be abandoned, as it had no pathological meaning. Meningitis might be mild or severe, localised or general, but it was always caused by pyogenic organisms involving directly the meninges. When the infection was of low virulence, no organisms were found in the cerebro-spinal fluid, though there was an increase of mononuclear cells. If no abscess formed the meningitis frequently cleared up. Absence of organisms from a sample of cerebro-spinal fluid drawn off was of great prognostic value. Mild cases of meningeal inflammation tended to clear up spontaneously if the source of the infection was eliminated. Concerning meningeal abscess, he recalled Dr. Symonds's remark that for some reason unknown the infection in the route from ear to brain was stopped at the level of the lepto-meninges and formed pus, which was shut off, so that the infection was prevented from spreading throughout the sub-arachnoid space, and the brain was affected only superficially.
